IN the *Gardeners' Chronicle* for July, 1907, was published an illustration and my description of Dendrobium acuminatum, Rolfe. I regret this, as Mr. Oakes Ames, in his forthcoming Volume II. on *Orchidaceæ*, will describe and picture it as a new species under the name of Dendrobium Lyonii. The very much larger flowers than those of D. acuminatum were noted at the time, but were attributed to the vigour and size of the plants collected. Although a congener, it turns out to be distinct in many particulars. Mr. Ames writes that with the possible exception of D. superbum, it is much the most attractive species yet recorded from the Philippines. *Wm. S. Lyon, Manila, February, 1908.*

ORCHID NOTES AND GLEANINGS.

DENDROBIUM CRINIFERUM.

OUR illustration, taken from a photograph by Mr. Raffill of a plant which flowered at Kew, represents this curious little Malayan species which formed the subject of some interesting remarks by Mr. H. N. Ridley in the *Journal of the Asiatic Society*. Mr. Ridley calls attention to the regularity with which the "Pigeon Orchid"—D. crumenatum—flowers in its native habitat, and the singular fact that D. criniferum invariably opens its flowers in Singapore the day before those of D. crumenatum expand. The point is that whereas some species open their first blooms at different times, others keep time with the season with remarkable regularity. D. criniferum is an interesting species requiring to be cultivated in a warm house.

* CHAMAECYPARIS OBTUSA (*Sieb. et Zucc.*), FORM. FORMOSANA.—Strobili ut typicae, sed multo minores, 8 mm. in diametro, seminibus minoribus, cum alis 2 mm. in diametro.

† KETELEERIA FORMOSANA (*Hayata*), SP. NOV.—Ramuli dense papilloso-puberuli. Folia laxe inserta, plana, linearilanceolata, 30 mm. longa vel longiora, 5 mm. lata, nervis prominentibus, margine parum deflexa, in utraque facie vermicea, subtus vix pallidiora, apice obtusa (ramuli hornotini aristato-acuta) basi in pedem brevem compressum demum contortum attenuata. Strobili erecti, cylindracei, obtusi, 9 cm. longi, 5 cm. lati; squamae coriaceae, ovato-rotundatae v. cordatae, superne sensim attenuatae, apice subreflexae, basi breve unguiculatae, extus longitudinaliter striatae, puberulae, margine tennes, irregulariter serrulatae; bracteae squamis duplo breviores, spathulatae, membranaceae, dorso fuscae, apice cuspidatae vel trifidae, irregulariter serrulatae, ad medium contractae. Semina pallide fulva, basi acuta, cum ala concolore cultriformi, squamis aequilonga. Semen cum ala 27 mm. longum.

Hab. Shinjuki, Shinkocho, leg. N. Konishi, anno 1902.

ORCHIDS AT GATTON PARK, REIGATE.

The collection of Sir Jeremiah Colman, Bart. (gr. Mr. W. P. Bound), contains a remarkable display of Dendrobiums, most of them hybrids raised at Gatton Park. A fine feature was made of these in the group which secured a Gold Medal at the Royal Horticultural Society's meeting on March 3. Many of the plants are still in bloom, the Gatton Park variety of D. Cybele, which was awarded a First-Class Certificate, being a fine, distinct, and perfect flower, and one of the handsomest of the genus. In a new batch of D. Thwaitesiæ (splendidissimum grandiflorum × Wiganiæ) some very remarkable varieties are in bloom, the difference between the flowers of the plants being very great. The largest and darkest flower resembles D. splendidissimum grandiflorum, but the flowers are larger and tinted of a deep magenta rose, the base of the lip being claret coloured, with an orange disc. The other extreme of the same cross is a charming cream-white flower, with a light violet centre; three others are very dissimilar from either of those already named.

The raising of hybrid Orchids has been attended with much success at Gatton Park, and a very large proportion of the plants in the collection are of that class. Cymbidium Lady Colman, C. gattonense, Dia Cattleya Colmaniæ, and the very beautiful yellow and ruby-red hybrid Spathoglottis, recently commented on in the *Gardeners' Chronicle*, are most of them still in bloom, and among the Spathoglottis are some remarkable crosses yet to flower. Several of the low span-roofed houses are filled with thousands of hybrid Cattleyas, Lælio-Cattleyas, and other showy kinds. Quantities of various crosses of Sophro-Cattleya, Sophro-Lælia, and Brasso-Cattleya are nearing the flowering stage; and the hybrids of Odontoglossum, Cochlioda Noezliana, and especially Odontoglossum Edwardii, which has been largely used on account of its rich purple colour, are to be seen in all stages, and in the most healthy condition. Various crosses of some of the prettier "botanical" species have also been made, and some interesting results are expected. At the end of one of the houses which contain seedlings is a small batch of albino Cypripediums, including C. bellatulum album, C. Lawrenceanum Hyeanum, C. callosum Sanderæ, and C. Maudiæ magnificum; and at the moist and warm end of the next house a good batch of Cœlogyne pandurata, which regularly produce their light Apple-green and black flowers. These plants have all been obtained, by division, from a plant with about eight pseudo-bulbs, purchased a few years ago. The main corridor range connecting the ends of the block of larger Orchid houses has many Dendrobiums in bloom; some Phaio-Calanthe Colmanii, which has both white and rose-tinted varieties, lasting a long time in flower; a nice lot of Cœlogyne cristata alba and lemoniana; a good collection of Lælia anceps, principally white varieties (not in bloom); and some very handsome plants of finely-pitchered Nepenthes, together with many specimens of rare and interesting species.

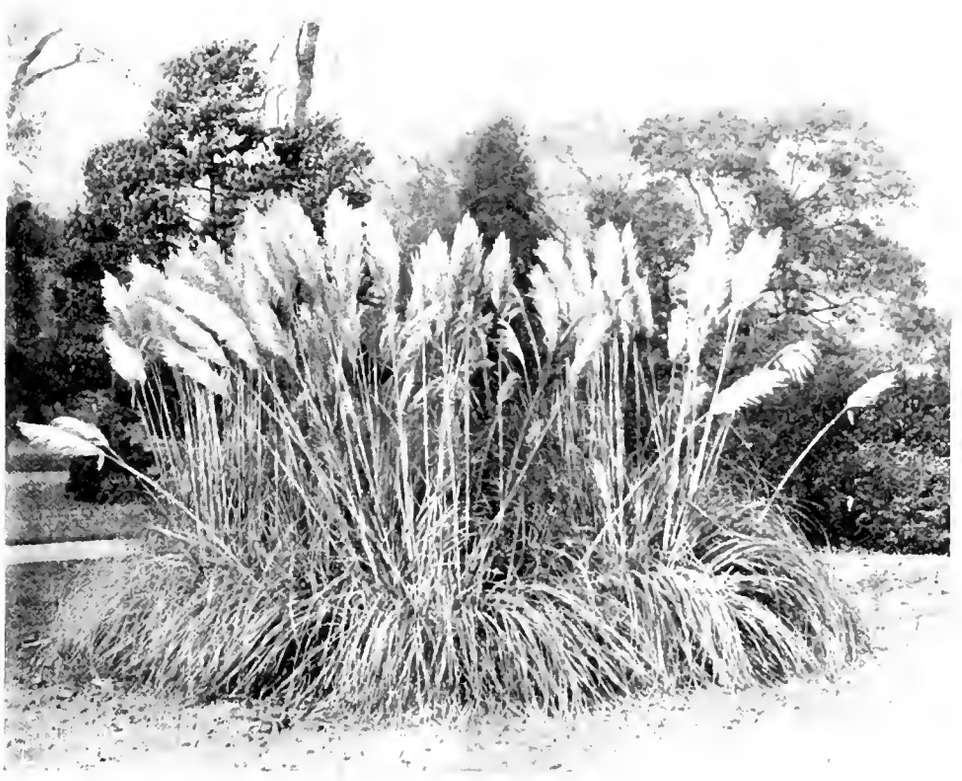
In the first house leading out of the corridor is a selection of plants belonging to the less showy species, including two species of the dwarf-growing Trias, a nice lot of Bulbophyllums and Cirrhopetalums, the rare and curious B. mandibulare, B. Pechei, C. refractum, and some others being in bloom. In other houses are a selection of Pleurothallis, Restrepias, Octomerias, and other small-growing species, among the prettiest in flower being Restrepia striata, and the densely-flowered, white, Angræcum hyaloides.

The Cattleya and Lælia houses contain many fine varieties of the showier species, a goodly number of pure white forms, and the most complete set in existence of albinos having a slight lavender or blue shade, or with white flowers, having lilac or blue colour on the labellum, that class being special favourites at Gatton Park. In flower in the Cattleya houses are some good varieties of Cattleya Trianæ, several hybrids, &c. The Odontoglossums are just commencing to flower, the plants throughout being well furnished with very stout flower-spikes.

In an intermediate house a number of hybrids of Epidendrum Boundii are in bloom, also E. × Boundii itself, which seems to remain superior to its descendants, the fine heads of yellow, orange, and red flowers being brighter than any of its class, and capable of lasting in bloom for a very long time.

Plants in flower in the other houses included several good Cypripediums; some fine examples of Cymbidium grandiflorum (Hookerianum), blooming among several other Cymbidiums; some pretty Masdevallias; the graceful Zygonisia Rolfeana; the violet-marked Zygocolax Veitchii Colman's variety, Saccolabium bellinum, Miltonia Warscewiczii, well-flowered, the orange-coloured Epidendrum aurantiacum, &c.

The smaller plants, and especially the store pans of seedling Odontoglossums, are suspended near to the roof glass, and the vigour of the Odontoglossums only 2 or 3 inches in height is pleasant to behold.



[Photograph by C. P. Raffill.

Fig. 82.—THE PAMPAS GRASS, CORTADERIA ARGENTEA.

Other very handsome Gatton Park hybrids are D. Chessingtonense Gatton Park variety, with yellow flowers and claret-coloured base to the lip; some very large and finely-coloured forms of D. Othello, and several new, light-coloured hybrids, one resulting from D. Wiganiæ × D. Wiganianum, being milk-white, with sulphur-coloured disc, and light purple base to the lip; D. Mrs. Alfred Rogers, a very floriferous kind, with delicate blush-white flowers, with soft green disc to the lip; and others of the class are in bloom, making quite a section of this delicately-tinted class.

Of species there are a good selection of D. nobile; the pure white D. Wardianum album, "Gatton Park variety," which has no other colour than the chrome yellow of the base of the lip; the fragrant pale yellow D. heterocarpum, D. signatum, and others. Dendrobium McCarthiæ, which does not succeed very well in most gardens, is grown most luxuriantly by Mr. Bound, who suspends it from the roof of a warm house near to the moist back wall of the structure.

THE PAMPAS GRASS.

(Cortaderia argentea.)

The Pampas Grass is amongst the noblest herbaceous plants in cultivation. Cortaderia argentea, illustrated at fig. 82, has few rivals for beautifying an open space such as a wide lawn or broad terrace. The plant is perfectly hardy in this country and increases in size with freedom; it may be readily propagated by division of the large thick tussocks. The species has been known under several names, succeeding botanists having conferred fresh titles, which in turn have been superseded. Thus it has been known as Arundo dioeca, A. Selloana, Gynerium argenteum, G. dioicum, and G. purpureum; this and much other information will be found in Dr. Otto Stapf's excellent monograph of the Pampas Grasses, published in the *Gardeners' Chronicle*, November 20, November 27, and December 4, 1897.

FRUIT REGISTER.

APPLE, HAMBLING'S SEEDLING.

This proves to be a most useful variety for March, an excellent cooker, and one that may also be used for dessert if ordinary dessert varieties are not available; the trees here are standards, planted in 1896, they have made good progress since that date, and will, I believe, eventually prove to be good bearers. The fruits are large, very even in outline, have the eye open, and the skin pale yellow; the flesh is firm and white. The general appearance of the fruit is very similar to that of the Duke of Gloucester, but this latter variety is ready for use in October. *W. H. Divers, Belvoir Castle Gardens, Grantham.*

TREES AND SHRUBS.

STACHYURUS PRÆCOX.

ATTENTION is frequently directed to the various shrubs which open their flowers during February and March, but it rarely happens that the above-mentioned plant is included in the lists. This is doubtless due to the fact that it is a comparatively unknown shrub except in the botanical gardens, notwithstanding that it has been in the country for nearly 50 years, is of distinct appearance and extremely ornamental. Though widely different from the Actinidias, Stewartias, and Camellias, Stachyurus is allied to those genera, being included in the order Ternströmiaceæ. S. præcox is a native of China and Japan, and is reported as found in many parts of both empires, frequently occurring in mountainous regions. When mature it is met with as spreading specimens 10 feet or so high, but requires very many years to attain to that height. The leaves are from 4 to 6 inches long, ovate-lanceolate and deciduous. The flowers are borne freely in axillary, drooping racemes 3 to 4 inches long; they are pale yellow in colour, and from 15 to 20 are borne on each inflorescence. Buds are formed in autumn and they remain dormant until early in February, the first flowers commencing to expand towards the latter end of the month. At Kew a bush, 2½ to 3 feet high and 4 feet across, in the vicinity of King William's Temple, is now (March 21) covered with its pretty catkin-like inflorescences, which have a very good effect against the reddish bark of the branches. At Kew this species is found to succeed best on light soil into which a little peat has been dug, and in an open position rather than in shade. *W. D.*

PROPAGATION OF IVIES.

THE Ivy (Hedera Helix), in its numerous varieties, is one of the most useful of all garden plants, for it may be utilised for many purposes, such as carpeting the ground beneath trees, for training in festoons along the terrace, covering unsightly buildings, forming edges to walks, &c. There are many beautiful variegated varieties of the common Ivy, and these are suitable for planting against walls, arbours, or pillars, or for furnishing hanging baskets and vases.

Suitable plants for the latter purpose can be obtained in eight months by grafting, and undoubtedly this is the most satisfactory method of increasing all the variegated forms of this popular climber, for it is a much quicker method of propagation than raising them from cuttings. The stocks for grafting may be raised from cuttings of the commoner varieties. An ordinary warm greenhouse is required for the grafting process, and if a propagating case is available in this house it will be an advantage, but it is not essential, as the pots may be placed on the ordinary staging if the atmosphere and surroundings are kept moist and the plants covered for a fortnight with a layer of paper. Before potting the stock, the bud or buds which are found at the base of the stem should be removed, to prevent the formation of suckers, and the stocks may be either established in pots when they are worked, or be potted afterwards. The grafting may be performed any time between November and March. Two buds should be retained on the scion and the ordinary method of whip grafting be employed, care being taken to finish the cut with an acute angle, thus enabling the scion also to make roots. An ordinary potting compost is all that is necessary for a rooting medium.

The "tree" or arborescent forms of the common Ivy have all originated from branches "in the adult stage" of the climbing varieties. These tree Ivies are admirably adapted for planting on lawns or in shrubberies. These are also best raised by grafting, and if two-year-old stocks established in pots are available they will be found an advantage, because large heads or branches can be used as scions, and consequently good specimens are obtained in a comparatively short time. Their subsequent treatment should be the same as that advised for the climbing varieties. *W. B. Little.*

NUTTALIA CERASIFORMIS.

THIS pretty Californian shrub is not by any means tender, for it succeeds in gardens in the neighbourhood of London. It is remarkable for being the first of the deciduous shrubs to put forth its leaves, the foliage buds often appearing in the months of February. Before the leaves are fully expanded the white flowers appear, carried in drooping clusters on slender sprays, which they almost entirely cover. In

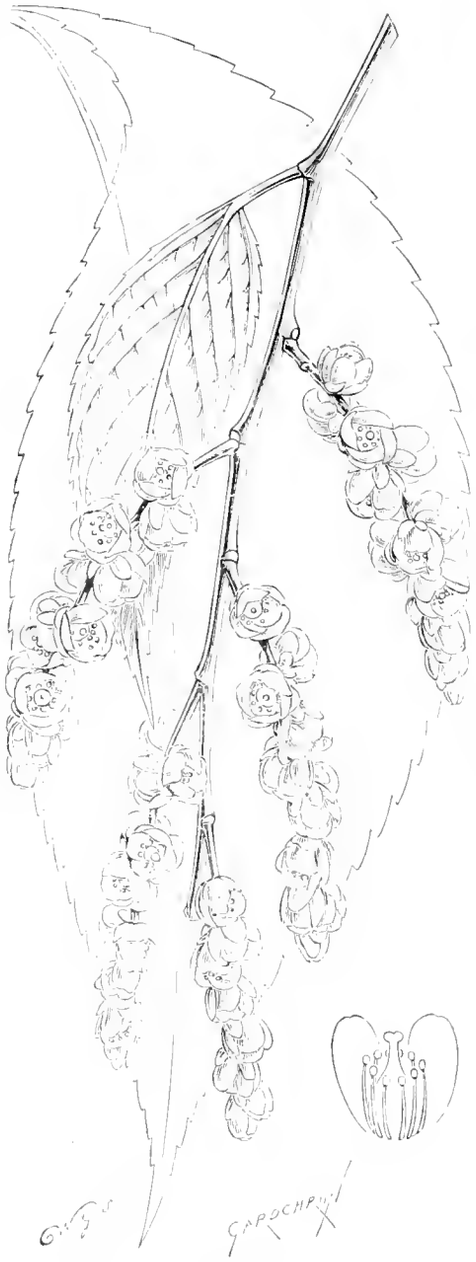


FIG. 83.—STACHYURUS PRÆCOX: FLOWERS PALE YELLOW.

their habit of growth they much resemble the far better known flowering Currant, Ribes sanguineum. In mild winters the flowers may sometimes be seen as early as the concluding days of January, but in ordinary winters they are fully three weeks later. A handsome specimen, over 8 feet in height and as much in diameter, growing in this neighbourhood, is always a pleasing sight in the early days of the year.

COCHLEARIA (IONOPSIDIUM) ACAULE.

THIS charming little annual is now a lovely sight in the garden, where it has propagated itself broadcast from self-sown seed. A sunny border where early bulbous Irises, such as I. alata, I. Danfordiæ, I. Histrio, I. histrioides, I. Rosenbachiana, I. Heldreichii or stenophylla, I. Tauri, I. orchioides, I. persica, I. Warleyensis, I. bucharica, and I. pavonia are growing, is now entirely covered with a veil of Lavender about 2 inches in height, out of which the arching leaves and flowers of the Irises appear. In another spot it has carpeted a colony of Chionodoxa sardensis, with its flowering growth and the deep blue glories of the snow look lovely spearing through the sheet of blossom. A single sowing suffices to establish this plant. In my garden some plants may be found in bloom in every month of the year. They spring up everywhere, flower and scatter their seed, and the seedlings soon come into bloom. The plant, being a very shallow rooting species, does no harm to anything, and, here, is never interfered with except to make room for fresh plants. A few years ago it unexpectedly appeared in another garden some distance away, where it had had never been sown. Possibly a seed or two may have been brought up with some bulb that was shifted. Its advent was welcomed with delight, and it has now spread all over the garden. It is particularly valuable, since it is in full flower during the months of January, February, and March, when the garden is rather bare of colour. It is a native of Portugal, and is sometimes known as the Diamond Cress. *S. W. Fitzherbert, Kingswear, Devon.*

NOTICES OF BOOKS.

* "THE GARDEN BEAUTIFUL: HOME WORDS AND HOME LANDSCAPE."

MR. W. ROBINSON is well known as an advocate for natural beauty in gardens, and this is the dominant note of his *Garden Beautiful*, though the gardens of which he is here thinking are rather the woodlands of his sub-title than gardens in the ordinary acceptation of the term. Many suggestive hints are given as to ways of planting the grounds for beautiful effects, treating the trees of the forest as really woodland plants and not merely as park specimens, but whatever one may think of this from the artistic point of view, we cannot always endorse his physiological reasoning. There is much vigorous writing against the rather vulgar prejudice in favour of variegated trees for the waterside, but perhaps all his readers will not agree with him in banishing the Copper Beech from such positions, however much they may admit the desirability of Willows for the actual water's edge. Some of the hints as to the woodland garden strike us as a little "inclusive" perhaps, having regard to the different requirements of Box and Gaultheria, for example, in the matter of soil.

Many readers would be glad to be able to agree with the author in his belief that London smoke will be overcome and banished before many years are passed, but it is difficult to feel sanguine as to the success of a park at Richmond to be devoted to evergreen forest trees. Unfortunately, the zone of evergreen luxuriance is rapidly shifting outward from the suburbs at the present time, and the prospect of its closing in, or even ceasing to retreat, seems a remote one. But whatever we may think of these things, those who read Mr. Robinson's book will certainly derive both instruction and enjoyment. It is impossible to end this brief notice without mentioning the beautiful wood-cut plates which form a most attractive feature of the book.

† "GARDEN LIFE" PICTORIAL GUIDE TO GARDENING."

UNDER the above title, the editor of *Garden Life* has brought out a useful work, interspersed with 220 illustrations. The very lucid manner in which the propagation of flowers, vegetables, shrubs, &c., are treated, as well as the errors in planting, &c., that are to be avoided, should make it especially attractive to amateurs. The moderate price at which the book is published places it within the reach of all.

RHODODENDRON COUNTESS OF HADDINGTON.

This hybrid, although one of the oldest, is amongst the most beautiful of the greenhouse Rhododendrons. As far back as March 19, 1862, the Floral Committee of the Royal Horticultural Society awarded a First Class Certificate to this plant, the exhibitor being Mr. Parker, of Tooting. The Society's *Journal*, 1861-2, describes the plant as "a vigorous-habited variety, evidently bred from R. Dalhousiæ. It has rather small, stout, dark-green, convex, ciliated leaves, and large long-tubed flowers of great substance, somewhat drooping and of a delicate blush-white colour." R. Countess of Haddington is of doubtful parentage, but is generally supposed to be the result of a cross between R. Dalhousiæ and R. Gibsonii. The plant represented in our illustration at fig. 84 is growing in one of the borders in the Temperate House at Kew, where one of the wings is largely devoted to the planting of these Rhododendrons. At this season of the year nothing more floriferous can be imagined than the view presented by these large specimens of Rhododendrons flowering in the huge building, with a setting of other handsome subjects around them. The visitor will find it difficult to determine which is more worthy of appreciation amongst such plants as Rhododendron Countess of Haddington, R. Veitchii, R. Veitchii lævigata, R. Fosterianum, R. Duchess of Edinburgh, R. Gibsonii, R. Princess Alice, and R. Lady Alice Fitzwilliam.

A plant of R. Countess of Haddington grown in Mr. J. Cypher's nursery, and measuring 6 feet by 6 feet, formed the subject of the Supplementary Illustration to our issue for May 19, 1888.

The section of greenhouse Rhododendrons which includes "Countess of Haddington" is of very easy cultivation in pots, tubs, or in the border of a greenhouse. They need a peaty compost containing plenty of coarse sand. Unless it is wished to raise seedlings, the seed pods should be prevented from forming, as these would otherwise impose a considerable strain upon the plants.

FOREIGN CORRESPONDENCE.

PHILODENDRON HYBRIDS.

I am much interested in the remarks applying to Philodendron × Corsinianum, published on pp. 25 and 69. Aroids still claim an important position among decorative stove plants, and admirers of them have a desire to know more about them than their habit and mode of growth. The statement of Mr. Watson, originally appended to the description of the plant in the *Bot. Mag.*, t. 8, 172, as being "the only hybrid Philodendron that has been raised," brought to my mind several other examples of hybrid origin in cultivation. One of them was distributed from the Cambridge Botanic Gardens, being P. gloriosum × Andreanum. Two others exist probably only in the Berlin Botanic Garden at Dahlem. These are: P. pinnatifidum × (?) Melinonii (or (?) Simsii) and P. pinnatifidum × Wendlandii. There is no reason to suspect that the latter two crosses exist in nature, as their habitats differ widely. P. pinnatifidum comes from Venezuela, P. Melinonii from French Guiana. P. Simsii occurs far more west, being a native of British Guiana, P. Wendlandii was found by Wendland in Costa Rica. P. gloriosum and P. Andreanum, however, are both growing in Columbia. Are these Philodendron hybrids but little known, or are they regarded as of natural production? There is no doubt of the Philodendron Lindenii, given by Dr. Ragionieri as one of the parents of P. × Corsinianum, to be P. Lindenii, Hort., which is a synonym of verrucosum Mathieu (like daguense Lind. et André, and Carderi Hort.), but what is meant by P. lucidum? *E. B. B., Berlin.*

— —The editor has kindly allowed me to read *E. B. B.*'s note. I had never heard of the Cambridge hybrid he mentions, and on enquiry I learn from Mr. Lynch that no Philodendron hybrid has ever been raised in the Botanic Gardens there, nor has one been cultivated there, so far as he knows. Mr. N. E. Brown, whose knowledge of Aroideæ is exceptional, is unacquainted with any hybrid Philodendron other than P. × Corsinianum. The two hybrids in the Berlin Botanic Garden have not, so far as I know, been previously recorded. *E. B. B.* does not state that they were artificially raised there. I know nothing of a Philodendron lucidum. *W. W.*

The Week's Work.

THE ORCHID HOUSES.

By H. G. Alexander, Orchid Grower to Major G. L. Holford, C.V.O., C.I.E., Westonbirt, Gloucestershire.

Deciduous Dendrobiums. The species and hybrids of this section flower late in winter and early in spring. Many of these plants will have now ceased flowering, and new growths may be seen pushing forth from the last made pseudo-bulbs. If such plants require to be repotted or top-dressed, the work may now be carried out. Young plants in vigorous health may be shifted into larger pots, taking care not to disturb the roots more than is necessary. Others that have sufficient rooting space and are well established in sweet material should not be disturbed more than is necessary in taking away a little of the surface material in order to apply a fresh top-dressing. Specimens which show signs of exhaustion from the strain of flowering should be turned out of their receptacles, and have all the old material shaken from their roots. Divide the plants and cut away all old and therefore useless pseudo-bulbs and dead roots, then pot up the divided plants into smaller pots to become re-established in cultivation again under ordinary conditions. For the purpose of re-potting employ a compost consisting in equal parts of Osmunda or Polypodium fibre and sphagnum-moss. The moss should be carefully cleaned and chopped before use. A fair quantity of rough sand and finely-broken crocks may be mixed with the compost. Ensure good drainage by filling the pots two-thirds of their depth with clean crocks and lumps of charcoal. Pot the plants moderately firm, keeping the base of each plant a little below the rim of the pot, and apply a thin layer of sphagnum-moss on the surface. These Dendrobiums require a strong heat, and moist but buoyant atmosphere during the season of growth, and exposure to sunlight, excepting that period when the growths are very young, or when more re-potting has taken place, when shading is necessary. During the early stages of growth only sufficient water should be given round the edge of the pot to keep the rooting medium just moist, as young growths are often shrivelled through allowing an excess of moisture. Later, when growth is more advanced, and the roots are extending freely in the compost, the quantity of water afforded may be gradually increased. Small plants should be

cultivated in receptacles that may be suspended from the roof rafters, while the larger ones can be best accommodated on an open trellis staging. Success in the cultivation of deciduous Dendrobiums depends largely on the plants being kept clean from insect pests. The plants are liable to attacks from almost every species that is known to infest Orchids.

Propagation.—It is a good practice to maintain a stock of young plants by propagating a certain number each year. This may be done by cutting off some well-ripened back pseudo-bulbs, choosing, as far as possible, those that have not bloomed. Cut these into short lengths and insert them as ordinary cuttings in pots filled with chopped sphagnum-moss and sand, or lay them on a bed of moss. They may then be placed in a warm, moist propagating case, when they will soon develop new growth. When the new roots make their appearance they can be potted off separately in the usual way.

Thunias.—When the young growths are about 2 inches long they will produce new roots freely. Re-potting is necessary every year, and it should be done before the new roots commence to grow. Shake all the old material from their roots, which, being dead, must be cut away, but not so severely that nothing is left to hold the pseudo-bulbs firmly when re-potted. These latter may be potted singly, or made up into specimens by putting five pseudo-bulbs in a 24-size pot, securing them to neat stakes. As abundance of water is needed when the plants are in full growth, good drainage is essential. The rooting medium may consist of two-fifths lumpy peat, two-fifths lumpy loam, and one-fifth chopped sphagnum-moss, adding plenty of crushed crocks and silver sand to keep the compost porous. Pot firmly, and let the surface be about one-half inch below the rim of the pot. Until new roots are made, the plants will not require much water. These plants may be grown in any plant stove where they can be exposed to full sunshine and be frequently syringed.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree, Hertfordshire.

Potatos.—Preparations ought now to be made for planting the principal crop of Potatos, especially by those who will plant them on high situations, or who reside in the southern and western counties. The earlier the tubers can be placed in the ground with safety the better it will be for the crop, as it prevents waste and the crop will more quickly mature. If a crop can be lifted early in the season, it is more likely to escape serious attacks of disease. All the tubers intended for planting should be carefully examined for the purpose of rejecting any which do not show signs of making strong sprouts. Large tubers may safely be cut a week or ten days before planting, at the same time dipping the cut parts into fresh lime. The cultivator should take out proper trenches, as this system is much to be preferred to that of planting the tubers in holes made by a dibber. A little "London" or stable manure should be placed in the trenches both before and after planting. This is especially necessary on heavy, retentive soils. I have also found Messrs. Wood & Son's Potato manure of much value in assisting the growth if applied both at the time of planting and again during the season of growth. If there are wireworms in the soil, apply a dressing of vaporite. In order to obtain specially good tubers some decayed leaf-soil may be mixed freely in the soil.

Asparagus.—The permanent beds should be neatly raked down, removing the roughest of the material, which should be retained in the trenches. Strictly avoid growing any other crops on the beds, but when space is a consideration a crop of Cauliflowers, Lettuce, Onions, or Radishes may quite safely be cultivated in the alleys, and in this case the beds themselves will afford shelter to such crops. Newly-formed beds should be planted not later than the first week in April.

Seakale.—Cuttings which were properly prepared at the time of lifting the crowns in the autumn should now be fit for planting out on land which has been deeply trenched and well manured in an open position in the garden. The rows should be placed at 18 inches apart, and distances of 1 foot should be allowed from set to set. It is a capital plan to cover the centres well over with finely-sifted cinder ashes, a sure preventive against the ravages of slugs. The cuttings should be dibbed in and made very firm. Established crowns in the permanent beds will now only need to have the air and light excluded to ensure perfect blanching, as the slower growth is made the finer will the produce be. All fermenting materials and the pots should be cleared away from plants which, having been forced, have yielded their produce; the crowns should be covered with fine cinder ashes and the ground between them neatly forked over.

Rhubarb.—This may be brought forward with the greatest of ease by placing pots or tubs over the permanent crowns, and as with the Seakale so with Rhubarb; immediately a fair quantity of stems have been taken from the crowns remove the coverings and expose them so that there may be plenty of time for the plants to make a good growth before the autumn.

Peas.—Make yet another sowing of the large podded varieties in boxes for subsequent planting out. Sow the seeds thinly and raise the seedlings in a cool house or unheated frame. A sowing should also be made in the open on land which has been deeply tilled and well enriched with good farmyard manure.

THE FLOWER GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

Hardy annuals.—I have recently prepared a border for hardy annuals. It is about 100 yards long and from 4 to 12 feet wide, of crescent shape, dotted at irregular intervals with bushes of Lavender, Rosemary, and occasional clumps of Lilium candidum, and has a background of shrubs. The ground has been deeply dug and enriched with manure. This work was done some time since, but we have recently forked over the surface soil and prepared it for receiving seeds. Many of these being very small, the soil should be made as fine as possible. Before sowing the seeds it will be necessary to consider the height and colours of the various species and varieties. We shall avoid formality as much as possible. At the back of the border the plants will consist chiefly of Sweet Peas of various colours, and planted in groups of various shapes and sizes, and corresponding, in a measure, with the irregular outline of the shrubs. There will also be occasional groups of such varieties as Mrs. George Higginson, Countess Spencer, King Edward, Dorothy Eckford, Evelyn Byatt, and Miss Willmott. There will be further groups of Lavatera rosea splendens, Lupinus Hartwegii, Linum grandiflorum, Nigella, "Miss Jekyll," Love Lies Bleeding (Amaranthus caudatus), Coreopsis (crimson varieties), Clarkia (Salmon Queen and double pink varieties), Chrysanthemums in variety, Cyanus, Candytuft (White Spiral, Carmine Empress, and Pigmy), Eschscholtzias, and Godetias in variety, Shirley Poppies, Bartonia aurea, Phacelia viscaria (cardinalis and dwarf carmine). The sorts already mentioned will be sown on the border, but the following species will be sown in heat, and the plants will have to be transplanted to the border at the end of May. These include Cosmus (useful for sitting-room and dinner-table decoration), Delphiniums Queen of the Blues, Nemesias, Phlox Drummondii, Kochia trichophila, Salpiglossis, Scabious, Marigold (Legion of Honour), Ricinus Gibsonii, Verbenas, Asters, and Stocks in variety. Wherever the seed is sown the soil should first be made fine and pressed moderately firm, either by treading, or, if the seeds are sown indoors, by the hands. Owing to the diversity of seed, they cannot all be treated in the same manner with regard to the depth of covering. The Sweet Peas, for example, should be planted from 2 to 3 inches deep; but Shirley Poppies are best when sown on the surface. As a general rule, seeds of every description are sown too thickly, and the plants afterwards become weakly through overcrowding. Very small seeds should be mixed with some finely-sifted dry sand, and they should be sown thinly. It may afterwards be necessary to thin out the seedlings as soon as they are large enough to be handled, thus providing space for each plant to develop to the greatest dimensions possible. The work of thinning should be done at a time when the ground is in a moist condition.

Pricking out.—Most of the seeds which are sown indoors will require to be pricked out as soon as they are large enough to be handled. Such plants include Antirrhinums, Dianthus, Petunias, Pyrethrums, Lobelias, &c. They should be pricked out into unheated frames, where they can be given protection from frost, if necessary, and ventilation can be employed to keep the growth as sturdy as possible. Other plants, such as Anchusa italica, Hollyhocks, Centaureas, Alonsoa gracilis, Nicotianas, Salvias, Carnations, etc., should be potted singly into small pots in a compost consisting of leaf-mould, loam, and sand. If the atmosphere is kept close for a few days afterwards, the plants will be encouraged to form fibrous roots quickly.

FRUITS UNDER GLASS.

By T. COOMBER, Gardener to LORD LLANGATTOCK, The Hendre, Monmouthshire.

Mid-season Grapes.—Vines that are intended to crop in mid-season, although at present in various stages of growth, require similar cultural conditions. Shoots that were left at the time of disbudding should now be stopped at two or three leaves beyond the inflorescence, according as the spaces between the rods are large or small. Let the shoots be trained down to the wires gradually. If it is attempted to draw them down at one operation, many of them will be liable to break off. Remove a considerable number of the bunches (or inflorescences) before the flowers open, leaving the final thinning to be done after the fruit is set, when a selection can be made of the most perfect and best placed bunches. The atmospheric temperature at night during the time the vines are in flower should be at about 60 to 65 degrees, this being enough for the free-setting varieties, but 70 degrees may be allowed for varieties of Muscat. These temperatures, however, should be permitted to fall a few degrees on very cold nights. The heat during the day-time may rise 5, or even 10 degrees above the temperatures already enumerated. When it has to be determined what bunches of fruit shall be left for the crop, it should be borne in mind that overcrowding of the vines would result in the production of fruits of poor quality, and, in extreme cases, shanking would be likely to follow. Until the flowers expand, the vines should be syringed with tepid soft water early in the morning, and again in the afternoon when closing the house, provided the weather is bright, but the syringing must be discontinued as soon as the blooms have opened. Damp the available surfaces in the house with water to promote moisture in the atmosphere, and pay strict attention to ventilation. During the actual flowering period, the atmosphere will need to be somewhat dry, and sufficient ventilation should be employed to cause the atmosphere to circulate freely. Artificial pollination should be carried out during the warmest part of the day, using the pollen from free-setting varieties upon the flowers of varieties that do not set so freely. Soon after the fruits upon free-setting varieties commence to swell, it can be seen whether the berries have been properly fertilised or not, and any that have failed in this respect should be cut out. A longer period, however, is necessary to determine these berries in the case of Muscat and other varieties that set their fruits with difficulty.

Melons.—The comparative absence of sunshine has not been favourable to the growth of Melons. Ventilate the structure with great care. Maintain the atmosphere moderately dry, and pay frequent attention to the pollination of the flowers and the stopping of shoots at one leaf beyond the fruit. If the fruits have commenced to swell, three of the most promising specimens upon each plant (if grown as cordons) should be chosen for the crop, and made secure to the trellis, removing all the remaining fruits. After this stage of growth the fruits will swell quickly, and liberal supplies of manure water or other suitable artifical manures and top-dressings will be necessary. The atmospheric temperature at night should be 70 degrees, allowing this to rise 10 degrees or more during the day if the weather is favourable. Close the ventilators early in the afternoon, and syringe the plants and damp all the surfaces in the house with tepid water. Attend to the sowing of seeds and transplanting of young plants for successional crops.

THE HARDY FRUIT GARDEN.

By F. Jordan, Gardener to The Dowager Lady Nunburnholme, Warter Priory, Yorkshire.

Grafting.—If the trees were "headed" or cut down, as advised in a previous calendar, the preparations for grafting may now be commenced, and as soon as the sap begins to circulate in the stem the actual process of inserting the scions may be carried out. The time for doing this will depend upon the season and the locality. In order to graft with success it is necessary to exercise the greatest care, and to use dormant scions which have been heeled-in under the shade of a north wall since December last. If the stocks to be grafted and the scions are of about the same size, the process of inserting the scions is simplified, and the method known as whip or tongue grafting is most suitable. Remove a portion of the top from the stock at the joint where it was cut, then make a slit in the bark of the stock in an upward direction. This slit must be made of the same size as the scion so that they will fit perfectly. Make a slit, or tongue, about half way down the cut surface of the stock in a downward direction, and a corresponding slit on the scion, and fit the scion into the stock. Bind the graft round with matting, firmly, but not too tightly. Afterwards apply clay or grafting wax over the matting to exclude moisture. The selected scions should possess from four to six buds each, the middle portion of a shoot being generally best. If much grafting has to be carried out, grafting wax may be purchased in tins from most of the nurserymen. If a limited number of trees are to be grafted, however, some clay, if worked into a pliable state, free from grit, with a little cow manure added, will do very well. [Directions for making a good form of grafting wax were also printed on p. 192 of the last issue. —Ed.] The clay should be covered with moss to prevent it cracking. It is necessary to exclude air until a union has taken place. Dwarf stocks may be earthed-up with soil, which will serve to keep the clay moist.

Fig. 85.—Whip or tongue grafting.

Cleft grafting (see fig. 86).—The method known as cleft grafting is useful for larger trees, being frequently employed in cider districts for the grafting of orchard trees. The unions resulting from cleft grafting are very seldom broken by strong winds. Choose short-jointed, well-ripened shoots for forming the scions, each having about four buds, and one of these should be near to the base. Cut the scion to the shape of a wedge, and open the stock with a mallet and chisel, inserting the scion before the chisel is removed. Two, four, or six grafts may be inserted by cleft or crown grafting in one stock, if the stock is a very large size.

Crown grafting (see fig. 87).—This process is similar to cleft grafting, and is preferred for use upon large branches. Remove a portion of the stock until a part is obtained which is smooth, and therefore in the best position for receiving the grafts. Make the ends smooth with a sharp knife, and cut the rind about 3 inches down the stock. Remove a portion of the scion for a similar length, leaving a small shoulder projecting that will rest on the top of the stock. It is necessary that the end bark should be made to join perfectly on both sides in order that a successful union may take place.

PLANTS UNDER GLASS.

By Thomas Lunt, Gardener to A. Stirling, Esq., Keir, Perthshire, N.B.

Dracæna Sanderiana.—This ornamental foliage plant forms a better specimen if several plants are placed together in the same pot or pan. At the commencement six or seven may be placed in a pot having a diameter of 8 inches. The compost should consist exclusively of peat and sand, and in the process of potting, this compost should be pressed moderately firmly. When the plant has established itself and has filled the pot with roots, an occasional application of an artificial manure containing iron may be given by sprinkling a little on the surface of the soil. This species should never be given liquid from the farmyard, as this form of manure causes the plant to lose its colour. When the shoots have grown to a height of 2 or 3 feet, they may be cut down to within 6 inches of the rim of the pot. This will cause the plants to produce young shoots from the base, and when these have become sufficiently long they may be staked out to form an effective bush-like plant. The ordinary temperature of the stove suits this species perfectly.

Helicenia illustris.—This species is also suitable for forming large specimens. It may be easily grown in the stove, but will not succeed if cultivated in a cooler atmosphere, exposing to cold for two days being sufficient to cause damage to the roots. The present is a good time to repot the plants. For furnishing a compost, mix together some rough pieces of light loam, peat, sand, charcoal, and broken bricks, with a liberal supply of chopped sphagnum-moss. The pots need to be provided with an extra amount of drainage material, as it is necessary to afford the plants a great amount of water during the season of growth. Shake the old soil away from the roots, and, in the potting process, carefully mix the fresh compost amongst the roots, and press them together moderately firmly. After the re-potting has been done, the plants will need to be syringed three or four times each day in bright weather. Maintain a high degree of heat, but do not apply water to the roots for some time after the re-potting has been done, for the water afforded by the syringings will be sufficient. Manure of the same nature as that recommended for Dracæna Sanderiana will suit this plant, which needs very liberal treatment when growing freely in order that the colour may develop well and the leaves grow to as large a size as possible.

Hoffmannia (Camptolobotrys) refulgens is another plant possessing fine foliage and suitable for forming large specimens. It may be started in the same manner as Dracæna Sanderiana, affording it a compost of loam, leaf-mould, peat, and sand in equal parts. Press this material firmly together, as the roots are of a fine nature. When the flower-spikes appear they should be removed, and, by liberal feeding with liquid manure obtained from the farmyard, the plants should be encouraged to make growth. When the shoots begin to hang over the sides of the pot it will be necessary to place two stakes flat on the pot, each of them 6 or 8 inches longer than the diameter of the top of the pot. Tie a hoop to each of the four corners. A good hoop may be formed of a piece of wire run through a piece of old half-inch garden hose. The shoots should be trained regularly over the hoop, and a plant may thus be grown until it measures 3 feet or more in every direction, making a most attractive specimen when suspended from the roof of a house. This species requires the temperature of a stove, and should be shaded from bright sunshine.

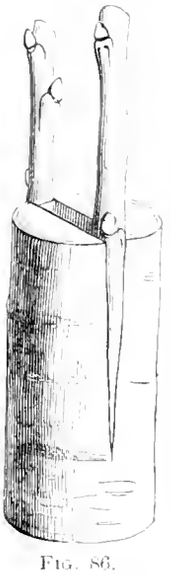

Fig. 86. Cleft grafting.

PUBLIC PARKS AND GARDENS.

By James Whitton, Superintendent of the Parks and Open Spaces in the City of Glasgow.

The provision of music.—In the month of March it is necessary to make preparations for providing musical performances in the parks and open spaces during the coming season. It is the custom in some towns to appoint a musical expert or director to assist the parks Committee in this matter; but in others, as in Glasgow, all the arrangements have to be carried out under the supervision of the park Superintendent. He submits his proposals to a sub-committee. It frequently happens that members of this committee possess a knowledge of music. The proposals, however, have to be drawn up with extreme care, because, in some cases, the amount of money that can be spent for this purpose is definitely specified by an Act of Parliament. The committee, when considering the arrangements for the season, have sometimes to refuse requests made by more or less influential bodies to have higher-class bands, as well as a greater number of performances in the districts they happen to be interested in. The employment of local bands is another matter demanding some tact and discrimination. In addition to high-class bands that are usually to be found in large industrial centres, there are always some who, being less efficient, are none the less energetic in their claims for recognition by the municipality. The committee may be anxious to encourage local talent, but it is commonly a waste of money to employ such bands, as the public would not be likely to listen to them. The public is fearless in its criticism of weak musical performances, and there should therefore be no hesitation in maintaining a high standard. In practice we give the lesser-known bands an opportunity to prove themselves by first employing them in the smaller parks and open spaces, and by their performances there it can be seen whether their services will be suitable for filling more important engagements. Another point meriting careful consideration is that of placing the bands. Our present system has been in force for some years with marked success, and it was inaugurated by the convener of the music committee. This system is to have a series of high-class bands playing in some park daily throughout the season. The bands are given weekly or fortnightly engagements, and appear in succession in the various parks. If a band is engaged from a distance, it gives two performances daily in different parks, thus affording residents in various districts an opportunity of hearing them. In the principal parks musical performances are given twice a week, and in secondary parks once a week, the performances in the smaller ones being at longer intervals. The desire that exists in a particular district for the band is judged by the attendances at the local performances. The actual music season commences in Glasgow about the middle of May, and extends to the second week of August. Performances are usually given between the hours of 7 and 9 p.m., except in cases where the bands have been brought from a distance, when they play during the afternoon in residential districts. In the selection of bands it is good policy, no matter how excellent the local bands may be, to employ a few high-class ones from a distance. Such an arrangement fosters a spirit of emulation, which is the mainspring of improvement in every profession. We have had such companies as Besses o' the Barn, Black Dike Mills, Wingate Temperance, Yorkshire Dragoons, Newcastle Artillery, Northumberland Hussars, and others, and occasionally one of the leading military bands from London, and, at still rarer intervals, one from the Continent. In regard to the composition of the bands, the military and brass bands are the best for outdoor performances. It having been found that, for the full enjoyment of orchestral music, shelter and perfect quietness are necessary, and these requisite conditions are rarely to be found in the vicinity of a bandstand in the public park.

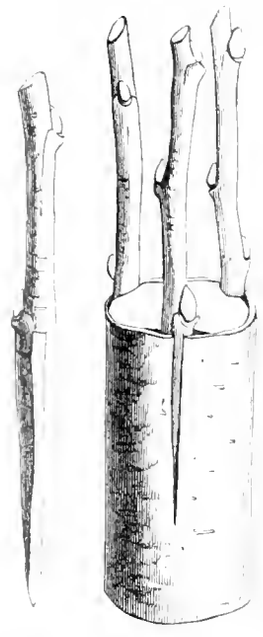

Fig. 87.—Crown or rind grafting.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS.

TUESDAY, MARCH 31—
Roy. Hort Soc. Coms. meet at Hort. Hall. (Prizes are offered for Hyacinths).

WEDNESDAY, APRIL 1—
Winter-flowering Carnation Soc. Spring Sh. at Hort. Hall, Westminster.

THURSDAY, APRIL 2—Linnean Soc. meet.

SATURDAY, APRIL 4—
Soc. Franç. d'Hort. de Londres meet. German Gard. Soc. meet.

TUESDAY, APRIL 7—
Brighton Spring Fl. Sh. (2 days). Cornwall Daffodil and Spring Fl. Soc. Exh. at Truro (2 days). Nat. Amateur Gard. Assoc. meet.

WEDNESDAY, APRIL 8—
Liverpool Hort. Assoc. Spring Fl. Sh. (2 days).

FRIDAY, APRIL 10—Exeter Daffodil and Spring Fl. Sh.

MONDAY, APRIL 13—
United Hort. Ben. and Prov. Soc. Com. meet.

TUESDAY, APRIL 14—
Royal Hort. Soc. Coms. meet. Brit. Gard. Assoc. Ex. Council meet. Nat. Rose Soc. Com. meet.

WEDNESDAY, APRIL 15
Roy. Caledonian Hort. Soc.'s Spring Sh., in Waverley Market, Edinburgh (2 days). Kent, Surrey and Sussex Daffodil and Spring Fl. Soc. Sh. at Tunbridge Wells.

FRIDAY, APRIL 17 *Good Friday.*

MONDAY, APRIL 20—*Easter Monday.* Bank Holiday.

TUESDAY, APRIL 21—
Huntingdonshire Daffodil and Spring Fl. Soc. Sh. at Huntingdon. Devon Daffodil and Spring Fl. Sh. at Plymouth (2 days).

WEDNESDAY, APRIL 22—
Roy. Bot. Soc. Exh. at Regent's Park.

THURSDAY, APRIL 23—
Midland Daffodil Soc. Sh. at Bot. Gardens, Birmingham (2 days).

SATURDAY, APRIL 25—
Quinquennial Exh. of the Soc. Roy. d'Agri. et de Botanique de Gand at Ghent, Belgium, lasting until May 2.

TUESDAY, APRIL 28—
Roy. Hort. Soc. Coms. meet, and Nat. Auricula Soc. combined show at Hort. Hall, Westminster. Shropshire Hort. Soc.'s Spring Fl. Sh.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich 42·7°.

ACTUAL TEMPERATURES—
LONDON. *Wednesday, March 25* (6 P.M.): Max. 53°; Min. 44°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London. *Thursday, March 26* (10 A.M.): Bar. 29·7; Temp. 45°; *Weather*—Slight rain.
PROVINCES.—*Wednesday, March 25* (6 P.M.): Max. 48° Cornwall and Ireland S.; Min 30° Scotland S.

SALES FOR THE ENSUING WEEK.

MONDAY AND WEDNESDAY
Sale of Bulbs, &c., at Stevens' Rooms, King Street, Covent Garden, W.C.

WEDNESDAY—
Lilies, Border Plants and Bulbs at 11.30; Roses and Fruit Trees at 1.30; Azaleas, Palms, &c., at 5, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

THURSDAY—
Herbaceous and Border Plants, Lily and other Bulbs at 12; Roses at 1.30, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

FRIDAY—
A selection of 300 lots of Hybrid Orchids from the Chessington Collection at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

Value of Records in Arboriculture.

At the commencement of the nineteenth century there was a considerable movement among the owners of estates in Great Britain in the direction of laying-out and planting of arboretums. It seems to have been the fashion at that date to make pleasure grounds and plant them with the new and rare trees and shrubs which were then being so largely brought from abroad; for a greater number of new species were introduced between 1800 and 1830 than had ever been brought into this country up to that time. Immense sums of money were spent on carrying out various schemes of landscape gardening and the grounds so laid out were all planted with various trees and shrubs. At about the height of the fashion, or perhaps when it was just on the wane, Loudon published his *Arboretum et Fruticetum Britannicum*, and one would have thought that the appearance of this book would have tended to keep up the interest in the subject of arboriculture, at any rate among the owners of arboretums, the trees in which had been referred to by Loudon in the statistics which he gives at the end of the description of each species.

Unfortunately for the cause of arboriculture, Loudon's mention of these specimens, giving their age, height, and girth, seems to have been, in most cases at any rate, labour thrown away; for except in the rarest instances is it now possible to identify with any degree of certainty the particular specimen at any given place that was mentioned. The loss to arboriculture in consequence is very great, for we are unable to learn anything from the life history of these trees. We do not know whether the tree which cannot now be traced was cut down, or whether it died from other causes. We do not know if it grew well or badly, whether the soil of the particular place suited it or not. Did some gale blow it down, or was some winter too cold? Why has it disappeared? What was the cause of its death? We cannot say. A century of experiment has thus been lost to us.

If the trees that Loudon mentions could have been periodically visited and their growth recorded at varying intervals, the reasons why they died or were cut down, and the quality of the timber stated, together with notes on the soil and situation, relating any exceptional gales and frosts which caused damage to the trees, an enormous amount of interesting matter could have been amassed, which would now be of incalculable service to those who are interested in the subject. The loss of this knowledge affects not only the arboriculturist, but in some degree the sylviculturist also; the former has, as a rule, the first chance of dealing with a new tree and judging of its characteristics and constitution. A tree is probably fairly well known in the arboretum before the forester attempts to deal with it. A new tree cannot as a rule be planted out on a large scale when it is first introduced into this country, for the difficulty of obtaining it in sufficient quantities is a bar to this, not to mention the loss which might be incurred by the owners of estates, who, though brave enough to experiment, should find out afterwards that the tree on which they had spent their money was not, after all, suited to this country, or that the local climate or soil did not favour its growth. In consequence, then, it is the arboriculturist who ought first to obtain useful knowledge with regard to a new tree, and he can pass on this knowledge to guide the forester in the choice of trees that he can plant with any expectation of success. The former plants chiefly for pleasure, the latter for profit; but the information the former could collect for the benefit of the forester is so great that it seems a pity the arboriculturist should not take more trouble to study each tree after it has once been planted.

It must be admitted that few people take an interest in both branches of tree-growing, and so the knowledge that might be obtained by one section is lost to the other. If one glances at the nurseryman's catalogues of some years ago one realises that some trees must have been distributed throughout the country in great quantities, but where are the specimens now? They have all presumably died, and so we naturally draw the conclusion that they will not thrive here. In regard to others, it might well be wrong to infer that they are not suited to any soils or any climate in the British Isles because they do not now exist; we cannot jump to the conclusion that because a tree may not be a success on one estate, it would be a failure on another where the conditions may be different. If only, as we have said above, Loudon's recorded trees could have been watched up to their death, much valuable information which has now been lost to us could have been obtained, and those of us who may be interested in this subject would not find it necessary to traverse the same grounds over which our predecessors have gone before us.

At the present time a good deal of interest seems to be arising again among many landowners in the planting of their parks and pleasure grounds with new and rare trees and shrubs. Some are fortunate enough to possess places where trees have already been planted, and they are now busy in planting either newly-introduced species or such sorts which, though introduced many years ago, are not already included in their garden. They may wonder why a certain tree is not to be found in their collection; they may think it curious that all the other trees introduced at the date when their collection was started are there, but not this or that particular one. The possession of properly kept records in such a case might have obviated further disappointment, as well as expense, by showing that failure had already attended the attempt to acclimatise it. Others who are not so fortunate as to own an arboretum are beginning for themselves to plant where no trees before existed, but it is to be hoped for the benefit of posterity that all who take up the planting of trees will keep some record of what they are doing and of the species that they are planting.

There are, of course, obvious difficulties to be met; human lives are so short, compared with the life of a tree, and it may take three or four generations before it is possible to form an estimate of the value of an introduced species. In some cases a man may take an interest in the trees that he has

planted, but when he dies his son may not; his son's son may however again take an interest in the subject, but if his grandfather has left no record of his successes and failures, he may have to experiment all over again, and in any event will lose much interesting information.

In other cases estates where trees have been planted are cut up for building purposes. Many trees are cut down, and are lost for ever, but if a record of them had been kept many details of permanent interest would have been preserved.

It is to be hoped that future planters will endeavour, even though in a small way, to keep some sort of log book of what they are doing. The difficulty in all cases is the identification of the particular tree which it is desired to study; it is necessary that it should have some sort of label attached to it to distinguish it, and it may be urged that the expense of this and the trouble of keeping them in repair is too great. In order to keep trees labelled as they are at Kew, for instance, it would necessitate great expense and labour, but such a method as this is not necessary for the requirements of the case. All that is absolutely necessary is to keep a log book of the trees planted; in this book should be stated the origin of the tree, stating either where the seed was obtained or where the young tree was procured, its pedigree, if any, and the date when it was planted; its dimensions could be added from time to time without much trouble. The tree could have a number assigned to it in the planting book, and this number could be affixed to the tree when it was planted out. At a very little cost (12s. per gross) numbers can be obtained stamped on metal, which would last indefinitely; a hole should be bored at the top of the label, through which a piece of copper wire can be passed, and the labels can be either suspended on the young trees or nailed on to the older ones. This would enable each tree to be identified for future reference.

Any note of interest could be added in the planting book as years went by; when it bore fertile seed, if at all; when it was mentioned in any book on the subject, and so on; then the difficulty of identifying that tree again would be enormously reduced. We should know what had happened to the tree in question, whether it had a constitution that could withstand frost or wind, whether the drought of a certain summer was too much for it; whether we were wise in planting that tree on a large scale or whether it would be unfitted for planting for purposes of profit. As each was cut down, its timber could be examined to see how it compares with that obtained from abroad, and a note of this could be added in the book. In this manner the arboriculturist could materially help the sylviculturist in his selection of trees, and the former, although he may be pursuing his hobby for his own pleasure, would nevertheless have the satisfaction of knowing that he was at the same time contributing to the general stock of useful knowledge, and of adding materially to the value of his collection.

Our Supplementary Illustration affords a view of the Pagoda in the Royal Botanic Gardens, Kew, a building which forms a conspicuous feature of the landscape, whether seen from the neighbouring towns or from the banks of the Thames, which forms the boundary of the gardens on the Middlesex side of the river. This Pagoda was built in 1761-2, at which period such architectural structures

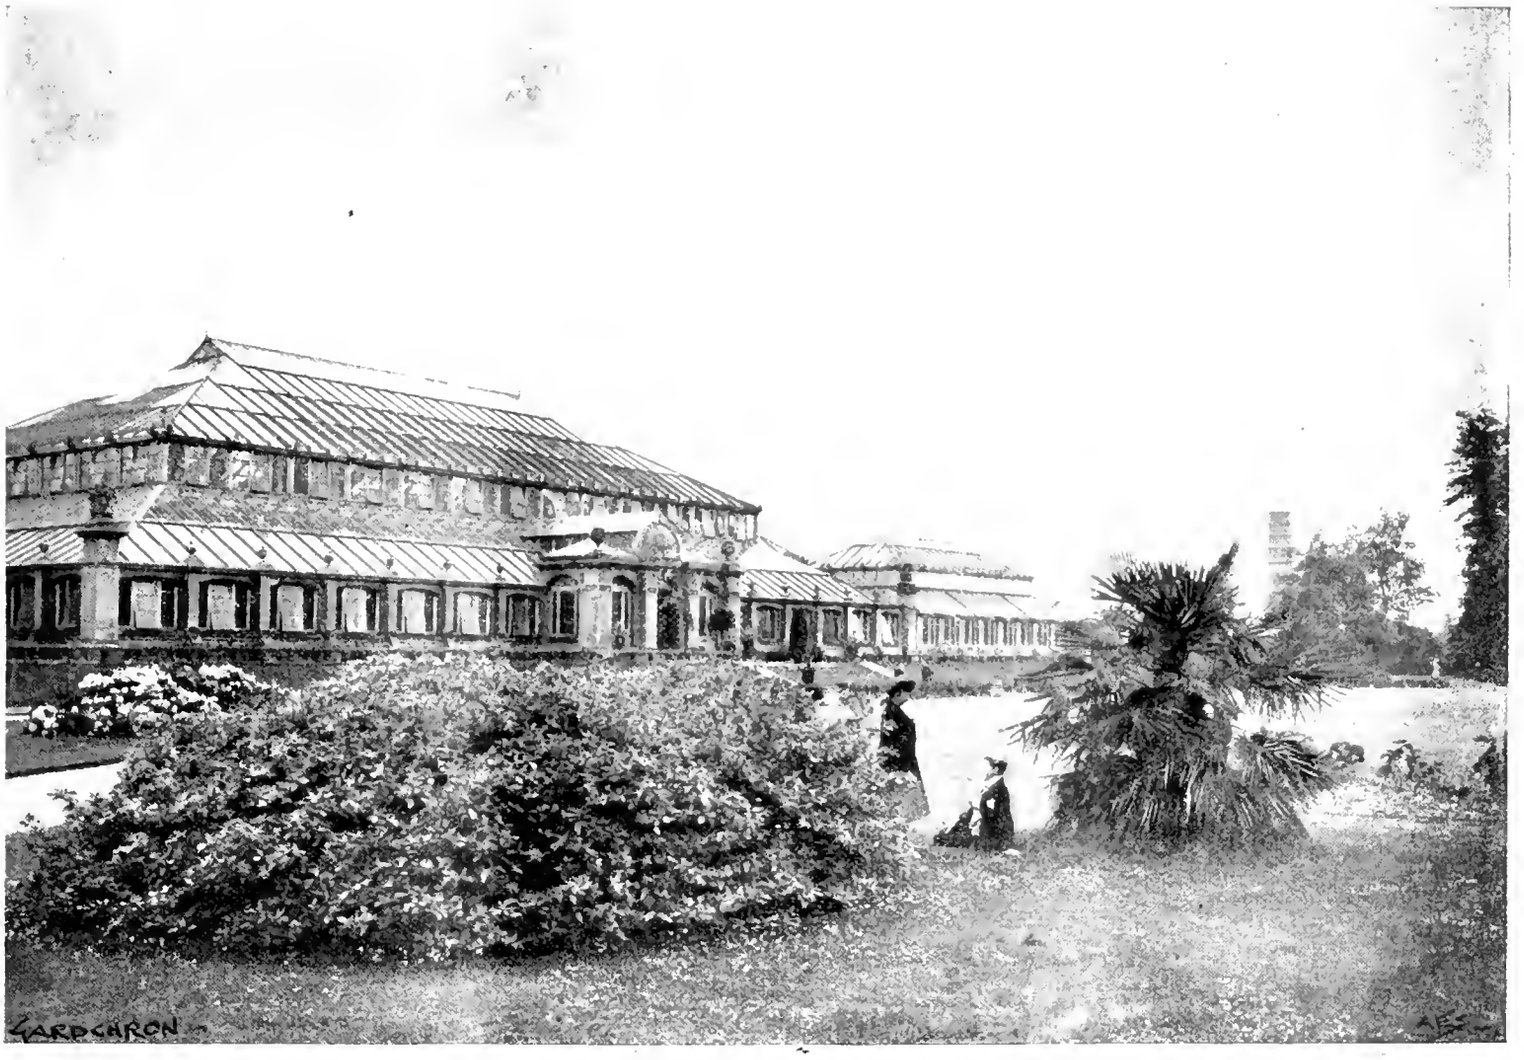

Fig. 88.—View of the Temperate House, Royal Gardens, Kew, with the Pagoda in the distance.

were considered fitting complements to garden scenery although they have long since fallen out of fashion. The substantial Orangery, which is now utilised as a museum, was erected at the same date as the Pagoda, and another building, known as the Mosque, which stood near to the Pagoda, was built in 1761. Sir William Chambers, the architect of Somerset House, and of the Kew Pagoda, erected a number of these buildings, many of which were built of fragile materials, and most of them have long since disappeared. The Pagoda is situated not far from the great Temperate House, of which we publish an illustration at fig. 88, and close to the town of Richmond. When the Pagoda was first erected, all the angles of the roof were orna-

mented with large dragons, 80 in number, covered with a kind of thin glass of various colours, but these have long since been removed. The building is not now open to the general public, although in former years visitors were permitted to ascend the winding staircase and view the gardens around. In the vicinity of the Pagoda is the arboretum, containing the rich collection of trees and shrubs for which Kew is famed, and the pretty sunken Rose-garden, which is so beautiful a spot in summer time. The building forms a fine setting at the far end of the broad vista which leads from a point near the great Palm House, past the still larger Temperate House. It is 49 feet in diameter at the base, and rises to a height of 163 feet. The circumference at the base is 87 feet 4 inches. The first storey opens on to a verandah, which extends to a distance of 15 feet from the building on all sides. Altogether there are nine storeys, and these are reached by a central staircase, consisting of 253 steps in nine flights. On each floor, except the bottom one, are four windows, their place on the ground floor being taken by doors, that alternate with recesses in which are seats. The windows in each instance open on to balconies, which are protected from the storey above by overhanging slate roofs. The building terminates in a tall staff that is surrounded with eight hoops and a cap.

THE TEMPERATE HOUSE, KEW.—We have on several former occasions given illustrations of the interior of this large plant-house. At fig. 88 a view is shown of the exterior of the main building and one of the wings, which latter is largely planted with Rhododendrons of the type shown at fig. 84. The building consists of five distinct portions, connected with each other, and were designed by DECIMUS BURTON. The extreme length is 628 feet, the central and largest section being 216 feet long, 140 feet wide, and 60 feet high, inside measurements. The two wings are connected with this main portion by octagon-shaped buildings, leading through lobbies, each 12 feet long and 7 feet wide. Each wing is 116 feet long, 64 feet wide, and 38 feet high. The front and back entrances to the main building include porches, each 12 feet long and 8 feet wide; the greatest width is therefore 164 feet, if these are taken into consideration. The octagons were built in 1861, the central portion was completed in 1862, the south wing was added in 1896, and the north wing in 1898-9. The total cost for the whole building was about £43,000. The hot-water system is heated by eight boilers, which are placed in crypts beneath the octagons. The whole building covers an area of nearly 2 acres, and stands on a raised terrace. A gallery runs around the central section at 30 feet above the ground. Further particulars will be found in an article published in the *Gardeners' Chronicle*, July 23, 1904, p. 55.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Committees will be held on Tuesday, March 31, at the Vincent Square Hall, Westminster. In the afternoon a lecture will be delivered by the Rev. Prof. G. HENSLOW, V.M.H., on "The History of the Cabbage Tribe."

LINNEAN SOCIETY.—A meeting will be held on Thursday, April 2, at 8 p.m., when the following papers will be read: Dr. HANS GADOW, F.R.S., "Altitude and Distribution of Plants in Southern Mexico"; Miss WINIFRED SMITH, B.Sc., F.L.S., "The Anatomy of some Sapotaceous Seedlings"; Dr. N. ANNANDALE, B.Sc., F.L.S., "Notes on some Sponges recently collected in Scotland."

HORTICULTURAL CLUB.—The next house dinner of the Club will take place on Tuesday, March 31, at the Hotel Windsor, when the Rev. JOSEPH JACOB will lecture on "Tulips."

THE GHENT QUINQUENNIAL.—The list of judges who have accepted invitations to officiate at the forthcoming exhibition has been published. There are 240 members, including representatives from Britain, Germany, America, Austria, Belgium, Brazil, Egypt, France, Spain, Denmark, Holland, Italy, Russia, Grand Duchy of Luxembourg, Sweden, Switzerland, &c. The English jurors are expected to include Messrs. JAMES BACKHOUSE, THOMAS BEVAN, H. GILLARD COVE, CHAS. H. CURTIS, HERBERT J. CUTBUSH, DE BARRI CRAWSHAY, — FINDLAY, J. GURNEY FOWLER, GEORGE GORDON, JAMES GUTTRIDGE, Major G. S. HOLFORD, R. W. KER, STUART H. LOW, W. H. MASSIE, JOHN MCMECKIN, F. W. MOORE, J. S. MOSS, GEORGE NICHOLSON, JAS. O'BRIEN, CHAS. E. PEARSON, R. HOOPER PEARSON, H. T. PITT, Col. PRAIN, Lord REDESDALE, JOHN ROBSON, THOMAS ROCHFORD, R. ALLEN ROLFE, F. SANDER, HARRY J. VEITCH, W. WATSON, JNO. WEATHERS, and BRIAN WYNNE. The jury will assemble on Friday morning, April 24, at 9 o'clock in the reception hall at the exhibition, and judging will commence shortly afterwards. They will meet again at 2 p.m., when luncheon will be served. At 5 p.m. there will be a botanical lecture by Professor NOEL BERNARD. At 8 p.m. members of the jury are invited to attend a performance in the Theatre Royal, which has been arranged by the society "l'Avenir Horticole." The exhibition will be formally opened by King LEOPOLD on Saturday morning, April 25, at 11 o'clock. At 8 p.m. on the same day there will be a reception at the Town Hall. On Sunday, April 26, at 11 o'clock, the monument erected to the memory of the late President of the Society, Comte DE KERCHOVE DE DENTERGHEM will be officially unveiled. At 1 p.m. the members of the jury are invited by the Chambre Syndicale des Horticulteurs Belges to attend a "Raoût," and at five o'clock the usual grand banquet will take place in the Theatre Royal.

THE YORKSHIRE GALA.—The council of the Grand Yorkshire Gala propose to send a deputation to the centenary show of the Société Royale d'Agriculture et de Botanique, which will be held at Ghent from April 25 to May 2. The members will leave Dover at 4.30 p.m. on April 23 for Ostend, and will subsequently proceed to the Grand Hotel Mengelle at Brussels, which will be their headquarters during the stay in Belgium. A visit will be made to the Ghent show on Saturday, April 24, and the party will return to England on the following Wednesday.

THE VEITCH MEMORIAL TRUSTEES.—We are informed that the trustees will offer the following prizes for competition at the shows of the Royal Horticultural Society. At the fruit show to be held on October 15 and 16 next:—A first prize of £10 and a Silver Medal, a second prize of £5 and a Bronze Medal, and a third prize of a Bronze Medal, for the best collections of five distinct varieties of Grapes, three bunches of each, to include two distinct white varieties, grown by the exhibitors only. At the meeting to be held on December 8 next, and at the first meeting in April, 1909:—One medal and £5 on each occasion for the best group of winter and spring-flowering Carnations, either in pots, or as cut flowers, or a combination of both, to occupy a space of 100 square feet, and grown by the exhibitors only. All these prizes will be open to competition by amateurs only.

HARDY TREES AND SHRUBS.—We are informed that Messrs. SMITH, ELDER & Co. will shortly publish a third and revised edition of Mr. A. D. WEBSTER'S work on *Hardy Ornamental Flowering Trees and Shrubs.*

THE NATIONAL HORTICULTURAL SOCIETY OF FRANCE.—The Spring Show will be held from May 22 to 29 next, in the large greenhouses, Cours la Reine, Paris. The schedule comprises 389 classes, divided into 18 sections. Those who cannot attend the Ghent Quinquennial will have an excellent opportunity of seeing a fine Continental flower show by visiting this one in Paris. A conference dealing with various subjects relating to horticulture will be held in conjunction with this show.

EARLY WORK ON THE CHRYSANTHEMUM.—The last three issues of *Le Jardin* have contained some interesting articles on the first book on the Chrysanthemum. It was published in Vienna in 1833 by Mr. J. P. RUPPRECHT. M. RENE MOMMEJA has made a translation from the German of the chronological and literary portion of the work, which, as Mr. HARMAN PAYNE points out in the current issue of *Le Jardin*, were not the result of original research on the part of RUPPRECHT, but largely borrowed from the writings of JOSEPH SABINE, Secretary to the Horticultural Society of London (now the Royal Horticultural Society).

THE FRENCH NATIONAL CHRYSANTHEMUM SOCIETY.—*Le Chrysanthème*, the official journal of the French National Chrysanthemum Society, has now reached its 101st number. We notice the Society now numbers 774 members, including 58 affiliated societies. Its next annual conference and exhibition will be held at Tours. Among other interesting articles we notice "Chrysanthemum Sports Exhibited and Certificated by the National Horticultural Society of France during 1907," and the text of one of the papers read at the Toulouse Conference by M. PERAGULLO last November.

THE GERMAN BOTANICAL SOCIETY celebrated the twenty-fifth year of its existence at Dresden on September 12 and 13, 1907, on which occasion eight honorary members and 26 corresponding members were added to the previously small number enjoying the distinction. Prof. BOWER, of Glasgow, and Colonel PRAIN, of Kew, are among the new honorary members, and Mr. W. BOTTING HEMSLEY, Kew; Mr. H. N. RIDLEY, Singapore; Dr. O. STAPF, Kew; and Dr. J. C. WILLIS, Ceylon, were elected corresponding members. In allusion to this selection, Dr. SCHWENDENER, the distinguished president, says the *Berichte der Deutschen Botanischen Gesellschaft*, stated that in selecting foreign members into its body, the society was animated by the sincere desire of showing its appreciation of the scientific work of the elected, and he trusted that the honour thus bestowed would be received in the same spirit. In the name of the society he sent greetings to the newly-elected members.

THE SOCIETY OF AMERICAN FLORISTS AND ORNAMENTAL HORTICULTURISTS will hold its first national flower show at Chicago on November 6 to 15 next. The society, in making this effort, will have the active co-operation of the American Carnation Society, the American Rose Society, the Chrysanthemum Society of America, the Illinois State Florists' Association, the Horticultural Society of Chicago, and the Chicago Florists' Club. An executive committee has been formed, consisting of nine chairmen of sub-committees. The general secretary is Mr. J. H. BURDETT, 1,411, First National Bank Buildings, Chicago, Ill.

Fig. 59.—View in the gardens at Compton Place, Eastbourne, one of the residences of the late Duke of Devonshire. (See p. 204.)

THE DUKE OF DEVONSHIRE. The lamented death of the Duke of DEVONSHIRE induces us to publish the view in the gardens at Compton Place, Eastbourne, shown at fig. 89, which has been prepared from a photograph taken by Mr. KING during last September. The deceased Duke was a liberal patron of horticulture, and the gardens at Chatsworth, Derbyshire (see fig. 90), which were formed by his predecessors, and which at one time were in the care of Sir JOSEPH PAXTON, have a world-wide reputation. The illustration of the gardens at Compton Place show a particularly pleasing portion of the pleasure grounds, known as the "Round" Garden, where the brilliant effects afforded by the beds of flowering plants are relieved by the presence of standard trees of ornamental species, and by other interesting features. It was at Compton Place that the late Duke carried out a considerable part of the entertaining for which he and the Duchess were celebrated. Fellows of the Royal Horticultural Society will remember that the site on which the old Chiswick Gardens were formed belonged to the dukedom of DEVONSHIRE, and that the Society eventually surrendered to the Duke their interest in the unexpired lease.

SALE OF "WESTFIELD" ORCHIDS.—The results of the first day's sale of the collection of Orchids belonging to FRANCIS WELLESLEY, Esq., Westfield, Woking, by Messrs. PROTHEROE & MORRIS, on Tuesday, March 24, tended to confirm the fact that, while there is a depreciation in the value of the commoner sorts, choice and distinct Orchids may be sold for higher prices even than formerly. A plant of Cypripedium insigne "Francis Wellesley" realised 100 guineas, and a small one of the same variety 32 guineas; Cypripedium Thalia giganteum, 66 guineas; C. Thalia Mrs. Francis Wellesley, 125 guineas; the very fine C. Æson giganteum, raised by Messrs. JAS. VEITCH & SONS some years ago, 220 guineas; C. Germaine Opoix Westfield variety, 280 guineas. The total receipts on the first day exceeded £1,700. The receipts on Wednesday, the second day, amounted to about £1,200.

THE FLOWERING OF THE ALMOND.—The first flowers on an Almond tree in a favourable position in Wandsworth, situated five miles south-west of London, expanded fully on Monday last, March 23, as against March 20 last year, February 28 in 1906, March 7 in 1905, and March 21 in 1904.

TREES AND SHRUBS AT THE ARNOLD ARBORETUM.—We have received the first part of the second volume of Professor SARGENT'S work on *Trees and Shrubs*, the material for which was mainly derived from the collection at the Arnold Arboretum. Amongst the species figured are several Chinese Viburnums, *e.g.*, V. cinnamomifolium, described by A. REHDER. This forms a shrub or small tree, with dark, reddish-brown branches. Its handsome evergreen foliage makes it a valuable decorative plant for the grounds in temperate regions. Unfortunately, the flowers do not, from the horticultural standpoint, compare favourably with many of the other species of the genus. Several new species of Lonicera, collected by E. H. WILSON from Central and Western China, are also described. The price of the volume will be $5 net.

DEPARTMENT OF HORTICULTURE IN BELGIUM.—Replying to questions addressed to him on March 18 in the Belgian House of Representatives, the Minister of Agriculture, M. HELLEPUTTE, announced that the Government would reorganise the Board of Agriculture by creating a special department for horticulture, to be presided over by a separate council. We congratulate M. LOUIS GENTIL, the energetic and capable editor of the *Tribune Horticole*, and all who have worked in the cause, upon the perfect success which has rewarded their efforts.

NOTES FROM THE "FRENCH" GARDEN.

ALL arrangements in the French garden are now based upon the Melon crop. The making of the hot beds for the planting of Lettuces and Carrots is so arranged that the frames and lights may be available when the Melons are ready for planting in them.

Under certain circumstances frames and lights are specially reserved for the planting of Melons, and this system has been followed this season. The first batch will be planted this week. The hot beds were prepared on the 21st inst. Trenches 3 feet wide and 1 foot deep were dug, the soil of the first trench being placed in the path next to the last bed. A mixture of two-thirds fresh manure and one-third old, dry manure was employed, and this was trodden firmly, the top being formed 3 inches above the level of the path. The frames were next placed in position and filled with the soil removed from the next trench; in the centre of each light was placed half a barrowfull of well-decayed manure. The Melons were planted when the heat of the bed was 70° F. Previous to the making of the beds the young plants were cut back to two eyes, cutting the plants across the third node. The cotyledons or seed leaves were also cut close to the stem for the purpose of destroying the buds at this spot.

The planting of Cauliflowers amongst the Carrots on hot-beds has been commenced. The Cauliflowers were sown on the 15th of September, and pricked off during the first week of October in frames. The winter having been very mild has necessitated their being transplanted a second time in December, to check their growth and to induce greater development of the roots. The variety preferred for this batch is "Drianc urt." The crop will be ready for consumption in June.

The weather of last week has militated against the growth of the Lettuces and Carrots under the lights and cloches. Twelve degrees of frost were experienced on Thursday, March 19, and, although the cold has not been very severe since, the sky has always been overcast. Fortunately, we had taken the precaution of spreading mats over the lights and cloches at night-time, yet this protection has been insufficient on two occasions. The mats were allowed to remain on the glass till 10 or 11 a.m., by which time they lose their stiffness. *Paul Aquatias, Mayland, Essex, March 21.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

THE FLORIST'S ART.—I was pleased to note the generally appreciative remarks of your correspondent *E. M.* on the subject of florists' exhibitions in the issue of the *Gardeners' Chronicle* for February 29. Exhibitions of the florist's art are required in many centres, and Schedule framers should apportion prizes, medals, money, &c., at every big show. If competent florists could be induced to go round and discuss the merits, or the reverse, of the devices placed on view, it would effect great improvements in the art of displaying table and other kinds of floral decoration in the dwelling. So far, the methods now employed by the exhibitors of Chrysanthemums, winter-flowering Tree Carnations, Roses, Narcissus, Tulips, Sweet Peas, &c., are worthy of imitation in certain directions, and these are greatly superior to the older ones once so generally in vogue. Gardeners, like the rest of mankind, are copyists. There is no offence in this statement. But the models should be good ones, showing restraint in the matter of the species of flowers chosen; their colours, whether harmony or contrasts be required; and whether for effect in daylight or artificial light. There are incongruities in the choice of flowers and foliage which must be avoided by the decorator of the table, the jardinière, and the flower-stand. For example, the flowers of Orchids associated with overpowering out-of-doors subjects such as Rhododendrons, Azalea sinensis, Dahlias, and Chrysanthemums would certainly be unpleasing to most persons. Orchids afford the best effects when employed by themselves, although a mixture may be made with some of the more delicately-tinted Roses of the type of Niphetos or Devoniensis—to name Roses everyone knows—or even with some of the flowering Crab blossoms, which are just as fair. They might "go" well with Wistaria sinensis, with Forsythias and Irises. Among Roses there is great choice of varieties, especially in the so-called 'garden" Roses, as distinguished from the exhibition varieties. In the "garden" Roses it is the individual form that pleases, even more than the colour; then many of them have the charm of old acquaintance and of memory. The young gardener cannot know anything of these points in the Rose. It may come to him, too, if he chance to live long; but to those advanced in life it is a rare pleasure to behold these old favourites. I am not sure that a simple low bowl of one or two varieties of the Rose cut with quite short stalks is not more pleasing to most persons than the flamboyant blooms with stalks of 2 feet in length, stuck into those most prodigious cylinders of glass in which they are shown at exhibitions. These American Roses and pretentious methods of display may not perfectly suit the average Briton, and I anticipate a return to the use of the older short-stalked Rose and its accompanying buds. *F. M.*

———The decoration of dwelling rooms, and especially of tables, is not always, as some persons imagine, an expensive luxury, for the hedgerows and ditches of almost every neighbourhood contain many beautiful flowers and foliage plants that are admirably adapted for this kind of decoration. There we may find flowers, grasses, Ferns, fruits, mosses, and beautiful leaves at almost every season of the year, and yet how seldom are these wildlings utilised for floral decoration indoors. Exotic plants, including Orchids, may be considered by some critics more ornamental, yet they lack the light, natural appearance of these plants of our hedgerows. Orchids, in common with all other flowers used for table decorations, should be arranged in a light and graceful manner, and their receptacles need carefully selecting. More prominence should be given to this branch of the gardener's art by the framers of exhibition schedules, who will find that the public interest in their displays is not likely to diminish, even if table decorations largely occupy the place at present held by groups of plants. *W. Fyfe.*

SUNSHINE AT VENTNOR.—To-day we have had nine hours' sunshine, and although the wind is from the east the weather is very warm. The past winter, like the two preceding winters, has been rather severe. Many people had planted Ivy-leaved Pelargoniums to grow up the walls under verandahs, and had covered them with mats, but the frosts have in most places killed them. In one garden the frosts during February have killed a fine plant of the Golden Aloe, which passed safely through the winter of 1906-07. Calceolarias that usually live out of doors from year to year have all been killed. Violets are very backward this year, but many other plants are in full bloom, such as Veronicas, Polyanthus, Double Daffodils, Primroses, white and blue Aubrietias, Tritomas, Wallflowers, Ribes, &c. People who have lived at Ventnor for some years say the winter climate is changing considerably, getting colder and more severe. *T. P., Ventnor, March 20.*

LILIUM GIGANTEUM. The finest specimen of Lilium giganteum I have grown in my garden produced six or seven offsets, of which the largest took fully five years to build up its immense flowering bulb. I think Sir Herbert Maxwell (see p. 172) is right in his affirmation that this great Lily usually succeeds well in fibrous loam impregnated with pulverised peat; but as I have already indicated, it also (unlike most other Lilies) grows admirably in a strongly fertilised soil. This indeed I feel sure is requisite in most situations for the attainment of its greatest possible height and strength. Extra nourishment is essential for a giant like this. *David R. Williamson.*

The Gardeners at Kew.—I should have taken no notice of such a letter as that signed *C. H. M.* if it had not been for the concluding remark, which implies that the fact of a man having been at Kew is a hindrance to his obtaining a good situation, and the assumption that a man who uses a lens and a notebook is not usually a practical gardener. I have seen the work of Kew gardeners in many places, and can say that several of the best and hardest-working head-gardeners I know, including my own, came from Kew; and they have told me that a good deal of their knowledge was gained there. It is a libel on the excellent staff at Kew to say that the majority leave there without little better scientific knowledge than they had when they went. The writer of this letter, like a good many so-called practical gardeners, does not seem to know what is meant by scientific knowledge, and if he can tell us of any garden at home or abroad where the general cultivation of all kinds of plants, together with neatness and order, is so well maintained as at Kew, I can only say that I have not yet to visit it. *H. J. Elwes, Colesborne.*

Leaf Curl of the Peach and Nectarine.—A wall tree of Peach Condor in these gardens is usually badly damaged by this affection, but last season scarcely a leaf was injured. In addition to a usual winter dressing with a fungicide and insecticide, I dressed the border in which the tree was growing with a mixture of superphosphates of lime, potash, and sulphate of iron, and possibly the sulphate of iron may have been partly responsible for the absence of "blister." My experience has proved that some varieties of Peaches are more susceptible to an attack of blister than are others, whilst a few are entirely immune from the disease. The neighbouring tree to the specimen of Condor referred to is of the variety Dymond, and whilst the former has always been more or less affected with blister, the disease has never been present in the leaves of the latter, although the branches of the two trees meet when tied out during the growing season. The Peach and Nectarine trees in these gardens are protected from frost and cold winds with shutters that are 2 feet wide and are hinged on to a skeleton frame, one side of which is fastened to the wall, the other side being supported by poles inserted in the border. When the weather is fine these shutters are turned back to the top of the wall to admit all the light. The front of the trees are covered with double-width "cheese-cloth" during the presence of frost or cold winds, and this protection is afforded from the time the buds commence to swell until all fear of danger from frost is over. *W. W., Doddington.*

The Species of Phormium.—Hitherto all the species and forms of the genus were considered to be perfectly hardy throughout Cornwall, but since the disastrous frosts of the beginning of January last this opinion has undergone modification. Except in the mildest parts of the county one hears the same tale of woe: "How are your species of Phormium? Mine are lying flat on the ground." As a rule, in Cornwall Phormiums are planted in moist situations, which, as Mr. A. J. Bliss shows in his interesting note, nearly approximates to the conditions under which they grow in New Zealand. They thrive amazingly under these circumstances, and unless the plants are copiously watered during the season of growth, it is the only way to realise to the full the beauties of the species. At the same time my experience agrees with that of Mr. Mallett, and I have found them to be far hardier when grown in "dry, well-drained soil," although even then they are not absolutely hardy. Mr. Bliss suggests that plants grown under drier conditions than those natural to them results "in a lack of vigour which renders it (them) less able to withstand a low temperature." This is quite contrary to my experience with half-hardy plants and trees. When grown under drier conditions, the growth made is usually harder, well ripened in short, and is better calculated to withstand a low temperature. For this same reason, when permanently planting any plants of a tender nature, I put them in a comparatively poor soil, planting them as firmly as is consistent with the well-being of the subject. The fact that the species of Phormium grow naturally in water is valuable, and may account for the hardiness of these plants, as observed by Mr. Bliss. It is generally known that the Arum Lily (Richardia aethiopica) is capable of withstanding over 20° of frost when growing in water, while a few degrees is often fatal to plants growing in soil in the open garden. I hope shortly to plant Phormiums in water. Contrary

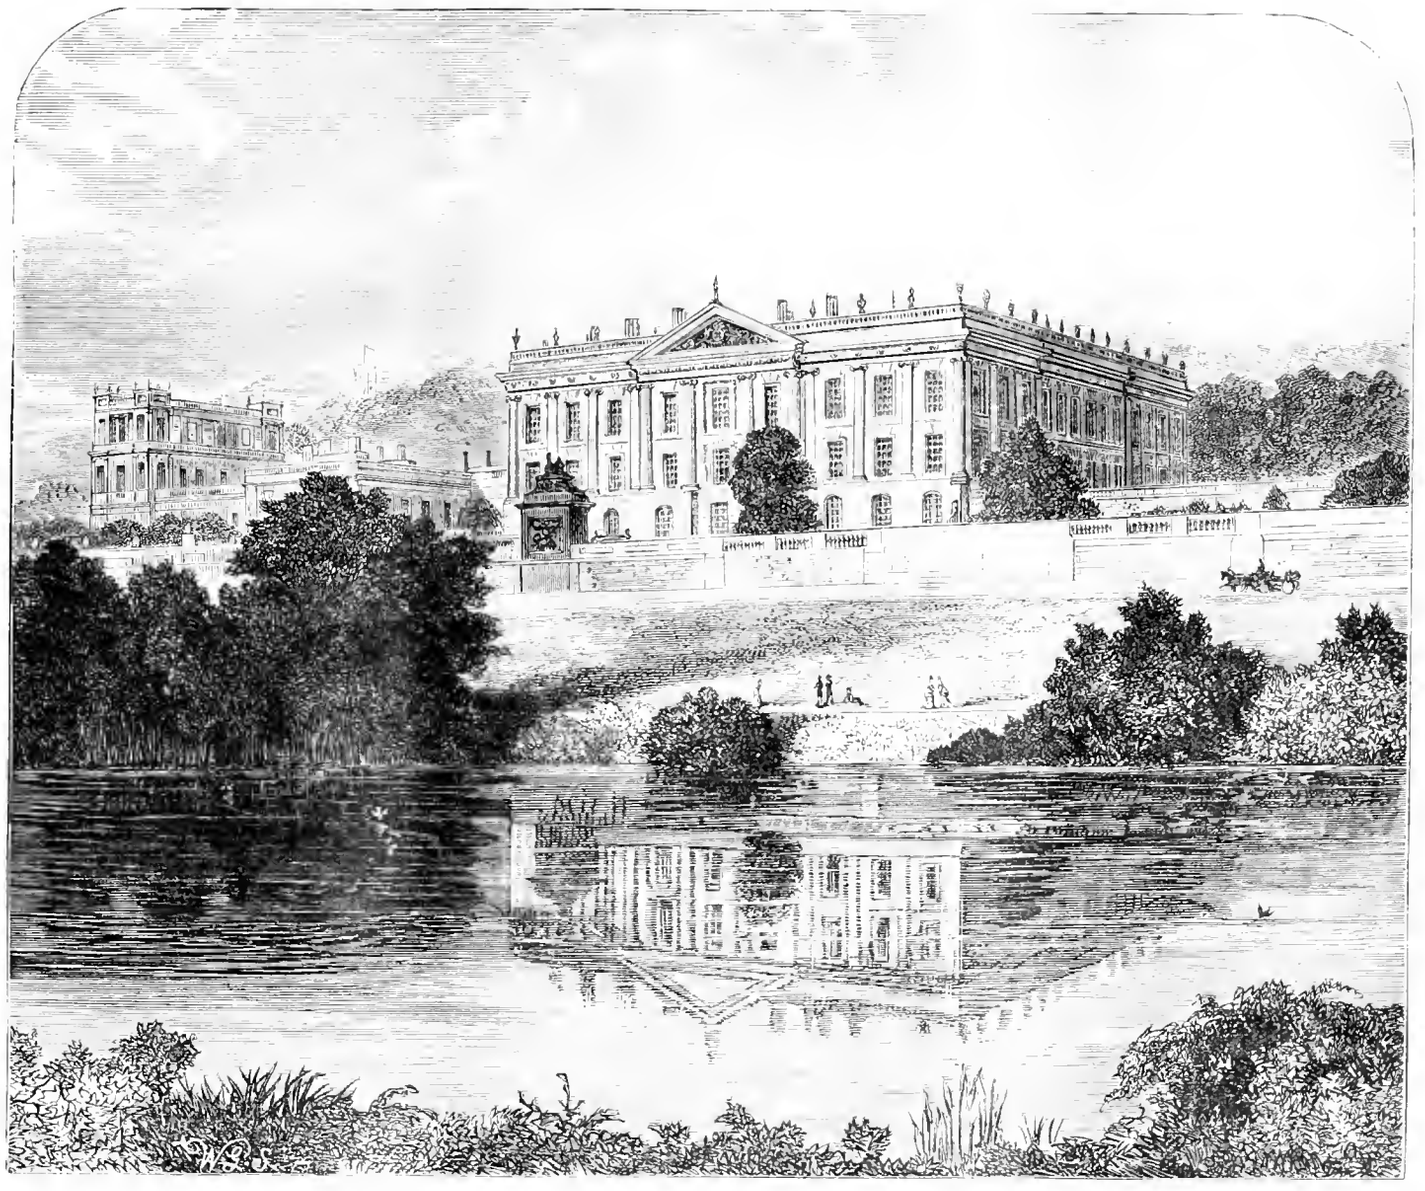

Fig. 90.—Chatsworth House, as seen from the River Derwent. (See p. 204.)

to Mr. Mallett's experience, I find that severed plants transplant most successfully provided it is done just as growth commences. As Mr. Mallett notes, seedlings of the variegated forms do not reproduce themselves. As a rule, they produce plants having leaves of the same shape as the parents, but without the colouring. Does not this failure to come true from seed disqualify them from being classed as varieties? [It shows that they are not species.—ED.] *A. C. Bartlett, Pencarrow Gardens, Cornwall.*

ARTIFICIAL MANURES.—I read an article recently in *The Country Gentleman's Estate Book* which stated it was much better to dig in artificial manures than to rake or harrow them in. The writer even asserted that it had been proved by experience that sulphate of ammonia and nitrate of soda gave immensely better results if dug in 7 inches deep. Is this the experience of any readers of the *Gardeners' Chronicle*? *W. C.*

MEALY BUG ON VINES.—Is there any preparation that will destroy this pest by means of fumigation or vaporising? I know there are many preparations that will destroy it by actual contact. For instance, paraffin, or mixtures containing paraffin. I had the impression that the XL-All vaporising compound was effective, but having given it four trials, my opinion is modified. The two last trials were made in a small, newly-constructed Cucumber house, and plants affected with mealy bug were placed on a temporary shelf near to the glass. A sheet of paper was put under them to catch any of the bugs that might drop, but I did not find one bug upon the paper afterwards. We remove the rough bark from our vines each year (though I do not like doing this), and I soak the rods with paraffin and soapy water, but mealy bug still makes its appearance each season. I am convinced that the pest is not in the border nor the woodwork, for the whole of the interior of the house is syringed more than once with a mixture of paraffin, and the border is covered with a thick layer of littery horse manure freshly obtained from the stables. I cultivate a few pot vines, and in consequence of the necessary reconstruction of the house last year, they were put to ripen in a structure which contained mealy bug. Before starting these vines in the following season, they were washed with a mixture of paraffin and soapy water, and on every bright day from the time shoots were 6 inches in length until the fruit had set, a few bugs were found, some of them fully developed, showing how rapidly they must grow and increase under the bark. It is only by frequent inspection and the use of a small brush and paraffin that we can keep this pest from gaining access to the bunches of fruit on our permanent vines. Red spider gives me little or no trouble, and thrip we seldom or never see. Mealy bug appears to be carried from one place to another in buckets and watering cans, and I have seen it on the men's garments after they have syringed houses containing overhead creepers. Until we get some kind of fumigation to destroy this pest, it appears we shall always be pestered with it. *W. P. R.* [Has our correspondent tried fumigation with hydrocyanic acid gas?—ED.]

CHALK PEAR (see p. 192).—This is a small Pear usually eaten by children; it ripens early in summer. The tree grows to a great size. It is common in Kent. *W. Roupell, Harvey Lodge, Roupell Park.*

SOCIETIES.

BRITISH GARDENERS' ASSOCIATION.

MARCH 21.—A meeting of this society was held at Carr's Restaurant, Strand, W.C., on the above date, for the purpose of establishing a London branch, as resolved at the meeting held on March 7. Mr. George Gordon, V.M.H., occupied the chair. The attendance included about 60 persons.

The Chairman, in his introductory remarks, stated that the formation of the proposed branch was very desirable, and that as many meetings as could be arranged to suit the convenience of members should be held, especially during the autumn, winter, and spring months.

Mr. E. F. Hawes moved that a London branch of the British Gardeners' Association be established for mutual improvement, and this was duly seconded and supported by several speakers, including Mr. Frogbrook, who pointed out the desirability of public bodies adopting some guide, such as the membership of the B.G.A. afforded, in selecting men for working in public parks and gardens. He stated that on a register of unemployed men with which he had to deal, 50 applicants were entered as gardeners, but they had no claim whatever to the title. Mr. C. Harding and Mr. George Hemming spoke in favour of the motion. The chairman then put the proposition to the meeting and it was carried.

It was next resolved that the name of the branch be the London Branch of the B.G.A., and that the affairs be managed by a committee of 12 members, with chairman, vice-chairman, and secretary. Considerable discussion followed relative to the election of the committee and officers, but ultimately the following were appointed:—Messrs. R. Lewis Castle, Cyril Harding, Thomas Winter, Thomas Lewis, Cresswell, Hill, Brien, Wood, Barnes, Parrott, Goreham, and Gibson, with Mr. E. F. Hawes, of the Royal Botanic Gardens, Regent's Park, as chairman; Mr. R. J. Frogbrook, of the Public Parks, Leyton, as vice-chairman, and Mr. Alfred James Hartless as secretary. It was decided that the meetings should be held at 7.30 p.m. in Carr's Restaurant, Strand, on the second Thursday in each month, the first to take place in April next. Each meeting will be open not only to members of the B.G.A., but to all gardeners who may wish to attend. The opening address will be given by Mr. E. F. Hawes on "The Present Opportunities of Improving Gardeners' Education."

——— At the last meeting of the executive council held on March 17, 25 new members were elected, bringing the total up to 1,188.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

MARCH 5.—*Committee present:* Messrs. E. Ashworth (Chairman), R. Ashworth, Ward, Warburton, Cowan, Cypher, Sander, Keeling, Shill, Ashton, Lœmann, Parker, Walmsley, and Weathers (hon. sec.).

The committee have decided to hold a special exhibition in St. James's Hall, Manchester, on April 1 and 2, and provision was made for a guarantee fund sufficient to cover all expenses. A good display of plants was seen at the meeting.

Messrs. CYPHER & SONS, Cheltenham, were awarded a Silver-Gilt Medal for a group of choice plants, in which were forms of Cattleya Schroderæ, several good examples of Dendrobiums, Brassavola Digbyana, Epiphronitis Veitchii, &c.

A. WARBURTON, Esq., Haslingden (gr. Mr. Dalgleish) was awarded a Silver-Gilt Medal in the "Thompson" Competition, and a Silver Medal in the "Sander" Competition, for Cypripediums. Both groups contained well-grown specimens.

J. MCCARTNEY, Esq., Bolton (gr. Mr. Holmes), obtained a Silver Medal in the "Low" Competition, and a similar award in the "Thompson" Competition.

S. GRATRIX, Esq., Whalley Range (gr. Mr. Shill), obtained a Silver Medal for a choice group of plants, five of which received Awards of Merit (see below).

Z. A. WARD, Esq., Northenden (gr. Mr. Wetherby), staged a good group of Odontoglossums, which included a beautiful form of Odontoglossum Pescatorei called "Ward's variety."

Messrs. HUGH LOW & Co., Enfield, Middlesex, staged some well-flowered plants of Dendrobiums. The group contained some of the best forms of both species and hybrids, including D. × splendidissimum. (Silver Medal.)

A. J. BROMILOW, Esq., Rainhill (gr. Mr. Morgan) received a Silver Medal in the "Sander" Competition for Cypripediums.

W. BOLTON, Esq., Warrington, staged a group of Cattleyas and Odontoglossums. The most prominent plant in this collection was one of Cattleya Schroderæ—labelled C. S. var. Boltonii; the flowers possess as deep a colouring as those of the best type of Cattleya Warneri, and although the plant was not in a robust condition, the Committee awarded it a First-Class Certificate.

Mr. WEBSTER, Shackleton, Bradford, was voted a Bronze Medal for an interesting group of Orchids.

Mr. J. ROBSON, A'trincham, exhibited Cypripedium × Victor.

FIRST-CLASS CERTIFICATES were awarded to Cattleya Schroderæ var. Boltonii, shown by WM. BOLTON, Esq.; and Odontoglossum Pescatorei, "Ward's variety," exhibited by Z. A. WARD, Esq.

AWARDS OF MERIT were conferred on Cattleya Schroderæ var. splendidissima, and C. S. "Heys House variety," both shown by J. MCCARTNEY, Esq.; Brasso-Cattleya Thorntonii variety magnificum, Cypripedium × Orion variety aureum, C. × Lady Wimborne variety Crippsii, C. × exquisitum, Dendrobium × Wiganianum, Gratrix's variety, and Odontoglossum Wiganianum, West Point variety—these six were from the gardens of S. GRATRIX, Esq.; Cypripedium × aureum, Ward's variety, shown by Z. A. WARD, Esq.; C. × Leeanum, Warburton's variety, C. × Duchess variety Sappho, and C. × Euryades variety Mikado, these three were exhibited by A. WARBURTON, Esq.; and C. villosum variety colossus, shown by J. H. CRAVEN, Esq. *P. W.*

DUTCH BULB GROWERS' SOCIETY.

SINCE January last fortnightly meetings have been held by this society at Haarlem. Up to the present date the following awards have been made:—

First-class Certificate for single early Tulip Brilliant Star, orange-scarlet with black base; for Tulipa Fosteriana, a species with large scarlet flowers with yellow or black base; and for Hippeastrum procerum, a scarce, mauve-coloured species.

Awards of Merit for single early Tulip La Reine des Reines, a lovely shade of pink; and for the single early Tulip Hermann Schlegel or Primrose Queen, a sport from the well-known variety La Reine; the flowers are of light sulphur-colour, shaded white.

GARDENING APPOINTMENTS.

Mr. GEORGE PATERSON, of Messrs. LAIRD'S Nurseries, Edinburgh, as Gardener to W. H. ASKEW, Esq., Pallinsburn, Cornhill-on-Tweed, Northumberland.

Mr. F. LOVELESS, for the past 2½ years Gardener to P. H. STOTHERT, Esq., Woolley Grange, Bradford-on-Avon, Wilts, as Gardener to Col. MALLOCK, J.P., Friarmayne, Dorchester.

Mr. F. W. WISE, for the past 8 years Gardener at St. Catherine's House, Guildford, as Gardener to Miss M. H. DODGE, Loseley Park, Guildford.

Mr. WILLIAM R. BAILEY, late Gardener at Birlingham House, Pershore, Worcester, as Gardener to SAMUEL BAYLISS, Esq., The Wood House, Tettenhall, Wolverhampton.

Mr. H. MARTIN, for the past 3½ years Foreman at Beech House, Christchurch, as Gardener to C. A. HOGG, Esq., Alltrees, Coolham, Sussex. (Thanks for 1s. 3d. as a contribution to the R.G.O.F. box.)

Mr. T. HARRISON, for the past 6 months Gardener to Mrs. LANGFORD BROOK, at Mere Hall, Knutsford, as Gardener to J. W. PROCTOR, Esq., at the same address. (Your contribution has been placed in the R.G.O.F. box.)

Mr. JOHN GILLIES, Foreman at Warter Priory, previously employed at Frogmore and Sandringham Gardens, as Gardener to Mrs. GERARD LEIGH, Lees Court, Faversham, Kent.

Mr. FREDK. STREETER, for the past 2 years and 4 months Gardener to the late Mrs. B. F. BARTON, Birtley, Bramley, Guildford, as Gardener and Bailiff to H. S. BARTON, Esq., Hewshott House, Liphook, Hants.

Mr. JOHN BURROWS, for 4 years Gardener to the Rev. D. F. WRIGHT, at Langar, and previously 22 years in the Herbaceous Garden at Shipley Hall, Derby, as Gardener to H. FITZHERBERT WRIGHT, Esq., West Hallam Hall, near Derby.

Mr. H. WHITE, for the past 6 years Gardener to the Hon. Mrs. GUY SCOTT, Money Hill, Rickmansworth, Herts, as Gardener to R. SLONE STANLEY, Esq., Bay House, Alverstoke, Hants. (Your contribution of 2s. has been placed in the R.G.O.F. box.)

Mr. HARRY WADEY, for the past 6 years Gardener to Sir BOURCHIER WREY, Bart., Tawstock Court, Barnstaple, Devon, as Gardener to E. POWELL, Esq., Lenton Hall, Nottingham.

Mr. G. W. LUCAS, for the past 2 years Gardener to W. GRAZEBROOK, Esq., Thenford House, Banbury, as Gardener to Mrs. J. LOCKER LAMPSON, Rowfant, Crawley, Sussex.

Mr. W. TEE, for the past 8½ years Gardener to H. STEVENS, Esq., Addlestone Lodge, Addlestone, Surrey, as Gardener to ARTHUR GIBBS, Esq., Birtley House, Bramley, near Guildford, Surrey.

Mr. DAVID MASON, for the past 4 years Foreman at Ford Manor Gardens, Lingfield, Surrey, as Gardener to J. S. BEALE, Esq., Standen, East Grinstead, Sussex.

MARKETS.

COVENT GARDEN, March 25.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—Ed.]

Remarks.—The first arrival of Black Hamburgh Grapes from Guernsey for this season has been received, but at present the fruit is unsold, and until the supplies of English Gros Colmars are exhausted they will not be likely to sell well. Cucumbers are cheaper owing to the increased quantities received. Cape fruit is not quite so plentiful and prices are higher. Rhubarb is dearer. Large consignments of Lemons are arriving, and the fruits are slightly cheaper. Barrel Apples are selling freely, especially the varieties Fallawater, Newtown Pippin, and varieties of the Russet type. Home-grown Beans are cheaper. The trade for vegetables remains good. *P. L., Covent Garden, Wednesday, March 25, 1908.*

Remarks.—The volume of trade is about the same as that of last week; the demand is good and the stock in London is small. *E. J. Newborn, Covent Garden and St. Pancras, March 25, 1908.*

COVENT GARDEN FLOWER MARKET.

Business has shown a slight improvement during the past week, but the cold weather has militated against the trade in hardy flower roots. Pansies of the best quality are seen with their first flowers expanded. There are few other hardy plants which sell so readily as these: boxes containing two dozen plants realise from 2s. 6d. to 3s. 6d. per box. These figures are wholesale prices, as are those given in the preceding columns, and of course retail prices are higher. Gardenias, which a few weeks ago were difficult to procure at prices ranging from 4s. to 8s. per dozen, can be purchased for 1s. 6d. to 2s. 6d. per dozen. Daffodils grown under glass are nearly over, and owing to the cold weather those from the open will not be in flower in time to succeed them. Roses are very prominent in the market: best quality blooms of Kaiserin A. Victoria, Mrs. J. Laing, Caroline Testout, Capt. Hayward, Madame A. Chatenay, Richmond, Liberty, and General Jacqueminot are plentiful. Carnations are abundant. Best quality blooms of the "Malmaison" varieties are the most valuable; the winter flowering varieties can be purchased at about half the price they realised a few years ago. Liliums are of uncertain value, some of the best blooms of L. longiflorum find buyers at 4s. per bunch, but many of lesser quality are sold at from 2s. to 3s. per bunch. L. auratum and L. lancifolium are both of good quality. Callas are very cheap. Daffodils have not advanced in value, though supplies are shorter.

Pot Plants.

There is little variation in this department. Mignonette is of better quality, and for best plants of the Machet variety 10s. per dozen is asked. Boronia heterophylla is obtainable: B. megastigma has not quite so large flowers as is usual, but good prices are maintained owing to a scarcity. Erica Wilmoreana is still very good, also E. persoluta alba. E. Cavendishii will soon be ready for marketing. Cinerarias are remarkably good. Indian Azaleas are becoming scarcer. Marguerites, Tulips, Hyacinths, Daffodils, Arums, Genistas, and Hydrangeas are all plentiful. There is no change to record in Palms, Ferns, and other foliage plants. *A. H., Covent Garden, Wednesday, March 25, 1908.*

CATALOGUES RECEIVED.

Thos. Bros., 133, London Road, Brighton—Farm seeds.

S. Mortimer, Rowledge, Farnham, Surrey—Carnations, Dahlias, &c.

Georg Egger, Jaffa, Palestine—Flower bulbs and roots from Palestine, Syria, and Asia Minor.

Barr & Sons, 11, 12, 13, King Street, Covent Garden, London, W.C.—Hardy Perennials, Alpines, Aquatics, &c.

SCHEDULES RECEIVED.

Darlington Horticultural Society's spring flower show, to be held in the Drill Hall, Darlington, on Wednesday, April 29, 1908. Hon. sec., Mr. A. H. Harrow, Priestgate House, Darlington.

Hemel Hempstead Horticultural Society's 49th annual exhibition and floral fete, to be held on Wednesday, August 19, 1908, in the Bury Grounds, Hemel Hempstead. Hon. sec., Mr. Geo. Burrows, Shendish Gardens, Hemel Hempstead.

National Dahlia Society's exhibition, at the Royal Horticultural Hall, Vincent Square, London, on Tuesday, September 3, 1908.

Sandiway and District Horticultural Society's third exhibition, to be held at Sandiway, on Saturday, August 15, 1908.

DEBATING SOCIETIES.

BECKENHAM HORTICULTURAL. At the meeting of this society, held on March 13, Mr. A. Dean, V.M.H., gave a lecture on "Annuals." The lecturer stated that for obtaining a display of these flowers in spring the seed should be sown in pots in autumn, and the plants be wintered in frames. If seeds of about a dozen varieties of annuals be mixed together, sown on a bed broadcast, and the plants be afterwards well thinned, an effective display of flowers will result. The lecturer gave a list of the best varieties for planting, including climbing varieties. *T. Cary.*

CARDIFF GARDENERS'.—The 22nd annual general meeting of this society took place at the Philharmonic Restaurant on March 17th, Mr. H. K. Farmer presiding. The hon. treasurer presented the balance sheet for the past year, and this was considered satisfactory. The hon. secretary's report stated that successful meetings had been held during the session 1907-8, and the society was making good progress. J. J. Neale, Esq., J.P., was asked to again officiate as president. Mr. H. K. Farmer was re-elected chairman. Messrs. T. Malpass and R. T. Weut were re-elected hon. treasurer and secretary respectively. The members of the committee were all re-elected, and three additional members appointed. *R. T. W.*

CROYDON & DISTRICT HORTICULTURAL.—A meeting of this society was held on Tuesday, March 17, under the presidency of Mr. F. Oxtoby. The lecture was delivered by Mr. W. Lintott, Marden Park Gardens, his subject being "The Cultivation of the Grape Vine." Mr. Lintott stated that the vine borders at Marden Park Gardens are formed of ordinary garden soil, but they are enriched frequently by top-dressings of decomposed organic matter, wood ashes, and mortar rubble, and this is well forked into the border before starting the vines into growth.

LOUGHBOROUGH GARDENERS'.—"Holiday Notes" was the subject of a lecture delivered, on March 17, by Mr. D. Roberts, Prestwold Gardens, who gave an interesting description of his rambles through the principal London parks, Kew Gardens, Hampton Court Palace, and some wholesale seed warehouses. The essayist gave a select list of the different kinds of plants used for bedding in the parks he visited.

READING AND DISTRICT GARDENERS'.—A meeting of this association was held in the Abbey Hall on Monday, March 2. The subject for the evening was "Violets," the lecturer being Mr. F. C. Loader, Holme Grange Gardens, Wokingham. Full cultural details were given under the following headings: Position of frames, time to commence operations, situation, preparation of soil, propagation, planting, early summer treatment, preparing winter quarters, lifting and planting, ventilation, watering, &c. At the meeting held on the 16th inst. the subject was "Some Insectarian Reflections," and was introduced by Professor Cole, of the Reading University College. At the outset the lecturer stated that he should treat the subject from a scientific rather than from a practical point of view. The various parts of an insect were dealt with, special reference being given to the organs of sight, smell, and flight. A description of the life history of the green fly brought a very interesting discourse to a close.

REDHILL AND REIGATE GARDENERS'.—The members of this association held their usual fortnightly meeting on March 17, Mr. Seaman presiding. Mr. D. Watson, a representative of the Guildford Gardeners' Association, gave a paper on "Wild Gardening." *G. P. S.*

WARGRAVE AND DISTRICT GARDENERS'.—The last two meetings of this association have been well attended. At the one held on March 4, Mr. T. Tunbridge, of the Gardens, The Three Elms, Remenham, read a paper on "Winter and Spring Bedding." He spoke of the preparation of the beds in the autumn, and gave a list of suitable plants, and stated how to combine them for best effect. Rockeries and wild gardens were also referred to by the lecturer. The meeting on March 18 was addressed by Mr. W. Pope, of The Willows Gardens, Wargrave, his subject being "Caladiums." The paper was short but practical. He described the attention necessary to ensure success, and dwelt on the kind of soil best suited to the strong and weak growing kinds respectively, shifting, watering, dividing the tubers, syringing, and general care during the growing season, as well as during the period when the plants are dormant.

THE WEATHER.

THE WEATHER IN WEST HERTS.

Week ending March 25.

A sudden change to warmer weather.—After 10 days of cold weather a change took place on the 23rd to warmer conditions. During the cold period in question there did not occur a single unseasonably warm day or night, and on the five coldest nights the exposed thermometer indicated from 13° to 16° of frost. On the coldest day during the past week the temperature in the thermometer screen never rose higher than 42°, whereas on the warmest day the highest reading was 57°—which is higher than any reading previously recorded here this year. At the present time the ground is at about an average temperature at 1 foot deep, but 1° colder than is seasonable at 2 feet deep. In the last three days the temperature at 1 foot deep has risen as much as 5°. Rain fell on three days, but to the total depth of less than ¼ inch. At the time of writing light rain has been falling without intermission for the last 21 hours. No measurable rain has come through the percolation gauge on which short grass is growing, and only small quantities through the bare soil gauge. The sun shone on an average for 3½ hours a day, which is half an hour a day short of the average for the time of year. The atmosphere was mostly calm, but on one day the mean velocity for the windiest hour amounted to 19 miles—direction S.S.E. The average amount of moisture in the air at 3 p.m. was 5 per cent. in excess of a seasonable quantity for that hour. An Early Rivers Peach tree growing on a south wall in my garden came first into blossom on the 21th, or two days later than its average date for the previous 22 years, and 3 days later than last year. *E. M., Berkhamsted, March 25, 1908.*

Obituary.

OTTO BALLIF.—The death is announced of M. Otto Ballif at the age of 50 years. M. Ballif was an authority on Orchids and a journalist of repute, having been for many years a member of the staff of the *Moniteur d'Horticulture*. If we are not mistaken, M. Ballif was of Swiss nationality, and resided for a short period in England.

Answers to Correspondents

CARNATION: *Fungi.* The plant is affected with the fungus Helminthosporium echinulatum. Pick off and burn every diseased leaf and continue to do this as long as the disease shows itself. Spray the plants occasionally with potassium sulphide, made by dissolving 1 oz. of potassium sulphide in a quart of hot water, afterwards making it up to 2½ gallons with cold water.

CASE OR BOX OF ORANGES AND LEMONS: *Fruit.* Oranges are packed in boxes containing 420 or 714 fruits; the Mandarin Orange is sent to the market in small boxes each containing 25 fruits. Lemons from Messina are sent in boxes of either 300 or 360 fruits; a box of Murcia Lemons contains 200 fruits. A box or case of Pomelo or Grape Fruit—Citrus decumana—may contain 54, 64, 80, or 96 fruits, according to the size of the box.

CHRYSANTHEMUM LEAF MINER: *F. B.* The eggs, from which the grubs are hatched, were deposited in the interior of the leaf by the perfect insect. As the miners are below the epidermis, or skin of the leaf, you cannot kill them by applications of poisonous compounds on the surface, and nothing will destroy them except picking off the affected foliage and burning it, or piercing the grubs with a large needle. The parent insect may be prevented from alighting on the foliage and depositing her eggs there by syringing the plants with some distasteful substance, such as quassia extract, or by dusting the leaves with Hellebore powder. Once the eggs are laid in the leaf the mischief is commenced. As the female insect is not present at this season of the year, the small dots on the other leaves you send are not concerned with the leaf miner. The insect that lays the eggs is developed from the grub which is burrowing in the leaves.

CORRECTION: In the report of the R.H.S. meeting in our last issue, Cypripedium Bridgei grandiflorum and other Cypripediums referred to on p. 190 as shown by F. Menteith Ogilvie, Esq., were exhibited by G. F. Moore, Esq., Chardwar, Bourton-on-the-Water, Glos.

CUCUMBERS FAILING: *E. F. T.* We find no disease present on the plants you send. The injury appears to have been caused by some external condition, such as burning by sunshine or by excessive heat from the hot-water pipes.

FAIRY RINGS IN GRASS: *Fairy Rings.* Remove the affected turf and burn it. Next take out the old soil to a depth of 1½ feet and bury it deeply in some distant part of the garden. Replace with fresh soil and sow the ground with grass seeds or lay turves. Treat the grass and soil in the neighbourhood of the infected area with a solution of permanganate of potash, made rather stronger than rose-red.

FRUIT SALESMAN: *Dorset.* You have not enclosed your name and address, according to the conditions on p. 200. Apply to Mr. H. Rides, Central Avenue, Covent Garden Market, London, W.C.

GARDENING IN INDIA: *S. P.* Firminger's *Manual of Gardening for Bengal and Upper India*, or Marshall Woodrow's *Gardening in India*, may be found suitable for your purpose. The former may be had from our publishing department, price 15s. 9d., and the latter for 7s. 6d. post free.

HIPPEASTRUM FLOWER. *H. S.* The portion of the inflorescence you send is injured by the Eucharis-bulb mite, of which plenty were found on examination. In all probability the bulb of that particular plant will be found to be badly infested with this pest, and if this is so, your best plan is to destroy the bulb by burning, and any others similarly affected.

HYDRANGEA FLOWERS: *A. P.* The plants can be made to produce blue flowers by watering the roots with a solution of alum water. There are many other contributory causes for the development of blue colour, as may be seen from the correspondence on this subject published in *Gardeners' Chronicle*, February 2, 9, 16, 23, and March 2, 1907.

MUSHROOM SPAWN: *H. D. C. P.* This is the name given to the mycelium or fungal threads of the Mushroom plant, and is usually sold in this country, ramifying in a mixture of manure and clay. These white cotton-like growths are equivalent to the plant proper, the Mushroom being really the fructifying organ only. In order to prepare Mushroom spawn, a mixture of manure and clay is moulded in the form of an oblong (the bricks, as they are termed), and whilst the soil is moist, a portion of an older brick containing some of the living mycelium is inserted in two or three places, and the new brick is placed in a warm, moist atmosphere. The fungus grows and permeates the brick, after which further growth is arrested by drying all the moisture from the cake of soil. The fungal threads will remain in a dormant condition in this hard, dry soil, to start into growth again when they are inserted in a suitable warm and moist medium. A bed of manure surfaced with a layer of soil is prepared in a dark, warm shed, and portions of the brick containing the living plant are inserted at intervals. This is termed spawning. In time the mycelium ramifies through the decaying vegetable matter, or manure, and at length produces its reproductive organs which, as we have already said, are known as Mushrooms.

NAMES OF FRUITS: *W. S., Cardiff.* The fruits are over-ripe. Send specimens earlier next season.

NAMES OF PLANTS: *J. H.* Cattleya labiata.—*F. S.* Eupatorium trapezoideum (syn. E. adenophorum).—*R. J. F.* 1, Cypripedium callosum; 2, Cypripedium Leeanum; 3, and 4, Dendrobium Pierardii.—*J. H.* Dendrobium Wardianum.—*A. F.* 1, is a poor variety of Cypripedium Leeanum, or a secondary cross of that hybrid; 2, this specimen is scarcely worth naming; 3, is a very distinct variety of Cypripedium nitens.—*J. K.* Velthemia viridifolia.—*W. G. S.* Odontoglossum loochristiense.—*W. P.* 1, Pelargonium quercifolium; 2, P. ardens; 3, P. betulæfolium; 4, P. crispum minor; 5, P. Radula major; 6, not recognised. You should have sent a shoot, rather than a single leaf only of each variety.

TOMATO PLANTS: *C. S.*—The plants are attacked by the "damping off" fungus—Pythium de Baryanum. Afford more ventilation and less moisture to the plants, and spread them well apart on the stage. If they are attacked when in the seed-pan dust the affected area with sulphur and lime.

VALUE OF IMPORTS OF PLANTS, BULBS, &C.: *M. C.* You will find particulars in the *Annual Statement of the Trade of the United Kingdom*, Vol. 1, 1906, published at 6s. 8d. This work deals with the subject up to the year 1906, and gives comparisons with the imports of previous years. A smaller publication dealing with 1907 only is *Accounts Relating to Trade and Navigation of the United Kingdom, 1907*, published at 1s. 2d. Another work which also contains information on the subject is *Agricultural Statistics*, Vol. xli., part iii., price 8½d. For these works apply to Messrs. Wyman and Co., Breams Buildings, Chancery Lane, London, E.C.

A NEW CHERRY DISEASE.

DURING the early summer of 1907 a fungus disease, affecting cultivated sweet Cherries, which does not seem to have been hitherto recorded from this country, was sent in to the College by several fruit-growers in Kent.

The first specimens were sent to me in June last from Ash, near Sandwich. The grower remarked that he had noticed it only on one tree during the season of 1906, but that by the next year it had spread "all over the orchard"; he concluded by remarking, "I am afraid I shall lose the trees altogether unless I can find a remedy."

The disease was again sent in during June by Mr. L. Levy, of Borden Hall, by Sittingbourne. Mr. Levy wrote that his fruit-foreman spoke of the disease as "red rust," and that he had observed it appear regularly on certain trees year after year, also that it had spread considerably during the last season or two, with the result that a large number of fresh trees were now affected.

I then received the disease from Mr. A. O. Walker, F.L.S., of Ulcombe Place, near Maidstone. A note accompanied it stating that only one branch of the tree was affected, but that that "looked very bad."

The disease was also brought to me from the Horticultural College, at Swanley, where it had appeared on a number of young trees recently planted. In this case the disease was having a decidedly injurious effect upon the growth of the young trees, and if it had

FIG. 91.—TWIG OF CHERRY WITH LEAVES (X) AFFECTED BY EXOASCUS MINOR.

not been attended to the disease would undoubtedly have spoilt their growth.

I have also seen the disease in a number of Cherry orchards in the neighbourhood of Pluckley and Charing.

The general appearance of the affected branches can be seen in fig. 91. The disease causes the leaves of the Cherry to curl, as shown at X, and at this stage they become pinkish-red in colour. Soon a delicate whitish bloom is visible spreading over the greater part of the under-surface of the leaf; then the affected leaves turn brown, and very

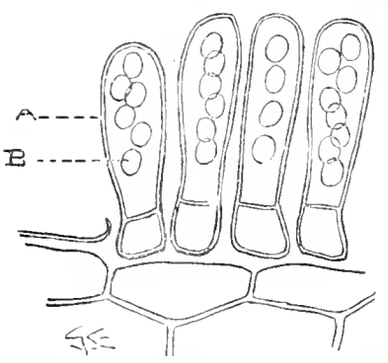

FIG. 92.—THE FRUCTIFICATION OF THE FUNGUS, EXOASCUS MINOR, BURSTING THE CUTICLE OF THE EPIDERMIS OF THE AFFECTED LEAF.

A, a spore-sac or ascus; B, an ascospore.

soon blacken and decay and rot off. Frequently only a single leaf on a branch will show the disease, in other cases two or three leaves scattered here and there will be affected, while, in rare cases, most of the leaves on a branch will be attacked.

If a section is cut of a diseased leaf at the time when the whitish superficial "bloom" is visible, and placed under the microscope, we shall find, projecting from the under surface of the leaf, myriads of very minute sacs (asci), each containing four, six, or eight spores (ascospores). (See fig. 92.) These little sacs are packed closely side by side, and extend continuously over the surface of the diseased part of the leaf, giving it the appearance of being covered with a delicate "bloom." When ripe, the ascospores escape from the sacs into the air, and are borne by the wind or insects to the leaves of other healthy branches, or to those of neighbouring trees, and are able at once to infect them, and so spread the disease.

The name of the fungus causing this disease is Exoascus minor Sadebeck. It is closely allied to E. deformans Fckl., which causes the "Leaf Curl" or "Blister" of the Peach, and also to E. Cerasi, the cause of the "Witches' Brooms" of the Cherry, a disease which will be described below.

As Sadebeck noted,* when first describing E. minor, the rapid decay and rotting away of the affected leaves are due to a large extent to the fact that various saprophytic "moulds" and other organisms are able to obtain free entrance into the inner tissues of the leaf after the cuticle has been destroyed by the serried ranks of asci breaking through it.

The spawn (mycelium) of the present fungus hibernates, that is, passes the winter, in the buds of the Cherry, and then in the spring grows forth into the young leaves, causing them to curl and become more or less wrinkled. Sadebeck notes that these leaves have an odour of cumarin, the scent of new-mown hay. The fungus then forms its fructification, consisting of asci and ascospores, on the under surface of the leaf, as described above, while the spawn grows along in the wood and into the new buds as they are formed, there to wait until, in the following season, the buds open out into the new leaves, which will then in their turn be attacked.

In large old Cherry trees it is seldom that more than a few branches are attacked, and the damage done is not often serious. But in the case of young trees, where it is necessary that all the wood formed should be healthy in order to produce a well-shaped tree, the present disease may become a serious pest. A badly-attacked young tree, if not attended to, will be permanently ruined, through the annual appearance of shoots bearing a number of diseased leaves which soon drop off and so cause the growth of the shoot to be arrested.

The disease can be cured by pruning. As the spawn of the fungus is perennial, living on from year to year in the buds and young wood, it is absolutely necessary to cut off each affected branch well below the last diseased leaf. The spawn does not extend backwards, or downwards, into the lower main branches or the stem, consequently the pruning will completely remove the disease. It is well, however, to spray during the first season with Bordeaux mixture using 4 lbs. copper sulphate, 4 lbs. quicklime, 50 gallons

* *Kritische Untersuch. ueber die durch Exoascus-Arten hervorgebrachten Baumkrankh.* (Jahrb. Hamburgisch. Wissenschaftl. Anstalt. viii., 24 (1890).)

water) at the time when the leaves are just expanded. Severe pruning on these lines, and spraying as directed, will restore to complete health in a single season Cherry trees which have been long suffering from the present disease.

As mentioned above, it does not appear that the present disease has been recorded hitherto as occurring in this country. Possibly it has been confused with the "Witches' Broom" disease caused by E. Cerasi, since in both cases the leaves on the affected shoots turn a pinkish—or carmine—red colour. E. minor is distinguished from E. Cerasi by the fact that it attacks only the leaves, never irritating the shoots so as to cause the formation of a "Witches' Broom." In this respect E. minor is similar to E. deformans, which causes Peach "Leaf curl." Further, the asci of E. minor are smaller, being 30-35u. long, and 6-8u. wide; they contain larger, oval ascospores, 6-7u. by 5u. E. Cerasi causes the production of large "Witches' Brooms," and forms longer and narrower asci, 35-50u. long, and only 5-7u. wide; the ascospores are smaller, and roundish, measuring 3-5u.

E. minor was first described by Sadebeck in 1890 as attacking "single shoots or shoot systems of Prunus Chamaecerasus Jacq.," near Hamburg, Germany. It does not hitherto seem to have been recorded from elsewhere. Tubeuf* states that it has been found on P. Cerasus.

We will turn now to the disease produced by E. Cerasi. This is what is known as the "Witches' Broom" of the Cherry, and occurs not uncommonly in Cherry orchards in England. In some parts of Kent I have heard it called "Bull wood," or "Bull branch." In France it is called "Balai du Sorcière," and in Germany "Hexenbesen."

The Cherry tree when attacked exhibits a curious malformation among the branches, so that at a distance it looks somewhat as though a bunch of Mistletoe were growing there. At the place attacked a number of long branches, close together, develop, growing out in a tufted manner from a single point, as it were, and thus forming a "broom"-like growth among the branches in the middle, or towards the outside, of the tree. The branches of the "broom" are frequently four to five times as thick as the surrounding healthy ones. This abnormal thickness is due to the irritation caused by the fungus-spawn living in the wood. The whole of the abnormal growth, resulting in the formation of a "Witches' Broom," is due to the attacks of the fungus E. Cerasi. The shoots composing the "broom" remain completely barren, never producing any flowers. The disease is most apparent in the spring, at the time of the blossoming of the Cherry, because then the diseased branches forming the "broom" break out precociously into leaf, as is shown in fig. 93, while the rest of the branches are covered with blossom. The "brooms" in a tree become consequently very conspicuous, appearing as little green bushes, as it were, in the midst of the white blossom-covered branches.

As the leaves on the diseased branches unfold, they turn to a carmine-red colour. If at this stage a branch is cut off, it exhales after a little time a sweet smell like that of woodruff, due to the presence of cumarin. Normal healthy shoots do not behave thus. Soon a whitish "bloom" begins to spread over the under surface of the leaves on the diseased branches. This "bloom" is in reality composed of a serried mass of naked asci breaking through the cuticle and projecting from the under surface of the leaf, exactly as in the case of the fructification of E. minor described above. By the time the "bloom" appears, the leaves on the surrounding healthy shoots are just expanding, and are thus exposed to infection by the ascospores as these escape from the asci on the leaves on the diseased shoots. We see, then, the reason for the precocious unfolding of the buds on the shoots of the "broom," and the important part it plays in the life-history of the fungus.

Fig. 93.—A branch of Cherry badly affected with Exoascus Cerasi, which has caused the branch to assume the character of a "Witches' Broom"

The ascospores on reaching a healthy leaf infect it at once, and the resulting spawn grows down the leaf-stalk, and penetrates into the wood. The spawn continues to grow forward into the young wood, which, as a result of being attacked, becomes abnormally thickened and lengthened, and further develops no fruit-buds—in other words, becomes the starting-place of a new "broom."

There are usually several "brooms" formed in a diseased tree, and the disease invariably appears on these year after year, even if the "brooms" do not increase in number. The damage done is appreciable; in the first place the mass of branches forming the "broom" is so much absolutely barren wood; in the second place, the "brooms" in their vigorous growth use up a good deal of food-material which should go to the making or ripening of healthy wood.

Now, the spawn of this fungus does not extend backwards (downwards) into the tree; consequently if all the "brooms" are completely cut out of a Cherry, that tree stands completely healthy again. If, however, there are trees with "Witches' Brooms" in the neighbourhood, then it is necessary to spray with Bordeaux mixture (as described above) at the time when the leaves are just unfolding, as otherwise they will be liable to be infected by the air- or insect-borne ascospores.

This disease, like the Cherry Leaf Scorch, is one for which the co-operation of fruit-growers is required before it can be entirely exterminated throughout a district. I have repeatedly seen a number of good Cherry orchards situated close together, all suffering from this disease, the various owners not having thought it worth while to cut out the "brooms," which have in consequence increased from year to year. Indeed, many growers seem to look upon the malformed growth of the branches forming the "broom" as something inevitably connected with the age, or nature, of the tree, attributing it often to the action of "physiological" causes due to some fault of soil or cultivation. Whereas it is entirely a fungus disease, and one which can easily be cured. The "brooms" are best cut out in the winter, at any time between October and February. They should always be removed and burnt before the fructification of the fungus appears. *E. S. Salmon, F.L.S., Mycologist to the South-Eastern Agricultural College, Wye, Kent.*

* Tubeuf, *Diseases of Plants*, p. 161 (English translation).

ORCHID NOTES AND GLEANINGS.

ORCHIDS AT BURFORD, DORKING.

The collection of Sir Trevor Lawrence, Bart. (gr. Mr. W. H. White), contains such an enormous quantity of pretty species as well as a fine representative collection of showy varieties and hybrids, that it provides an interesting display of flowers all the year round.

At the present time the greatest show is made by the Dendrobiums, the large house in which they are staged when in bloom having a charming bank of them literally covered with bloom, representing no fewer than 58 kinds, made up of species and hybrids, many of them in several distinct varieties. Among the hybrids it is interesting to note that some of the earlier introductions, when well grown, are as beautiful as those more recently raised. Good examples of this are D. euosmum virginale, D. euosmum leucopterum, and the very handsome D. micans. Several handsome forms of D. Clio, a select set of D. Wiganiæ, including a fine example of the yellow variety xanthocheilum; some of the best forms of D. nobile; several plants of D. Ainsworthii varieties, amongst which intertextum and other cream-white and yellow-tinted varieties predominate; the yellow D. Melpomene, and variety inversum; and the finer yellow Dendrobe raised at Burford out of D. signatum aureum, a good specimen of which is also in bloom. D. Kenneth (Bensoniæ × McCarthiæ), one of Mr. Cookson's hybrids has a very distinct and pretty flower; and the charming forms of D. melanodiscus, including chrysodiscus, Luna, Hebe pallens, and Rainbow, raised at Burford some years ago and frequently shown at the meetings of the Royal Horticultural Society, are still among the best of their class. Interesting and pretty species are represented by finely-flowered plants of D. Wardianum, D. crassinode, D. fimbriatum, and others of the showier kinds, with some specimens of D.

primulinum and D. cucullatum giganteum, which are often confused as one species, although the latter, as seen here, is slender, like D. Pierardii, and with a much larger pale primrose labellum than in D. primulinum. D. æmulum, D. Kingianum, and others of the smaller species are in bloom, together with the yellow and fragrant D. heterocarpum, and its variety album. In D. specioso-Kingianum, also in bloom, we have a link with the past, the plant having been raised, it is said, between D. speciosum and D. Kingianum by the late Mr. Spyers when Orchid grower at Burford many years ago.

These pleasant reminders of the earlier days of Orchid growing are not infrequent at Burford, where some of the specimens of Vanda suavis and V. tricolor have been in the collection about 30 years; some of the grand specimens of Phalænopsis now in bloom for nearly as long a period; while in the case of some of the curious species the specimens are the type plants. One grand specimen of Phalænopsis amabilis (grandiflora), with many large leaves, bears a branched inflorescence bearing more than 90 blooms; a large, old plant of the pink-tinted P. Sanderiana has 32 flowers, and there is a good show of bloom on P. Aphrodite, and other species, the fine white P. amabilis Rimestadtiana being one of the freest in growth and blossoming. In the same house, among other species in flower, are Angræcum bilobum Kirkii, with sprays of pretty white flowers; A. odoratissimum, the white Eria laxiflora, E. stricta, and Tainia penangiana. The Phalænopsis house is maintained as nearly as possible at an uniformly warm and comfortable temperature throughout the year. There are two critical times with these plants, viz., the middle of a hot summer, and the latter half of a dull, protracted winter, and much care is needed to tide the plants over these trying periods. Excessive heat in winter, especially at night, is the more dangerous by reason of its being attained by artificial means.

A long, cool, intermediate house has many Cœlogyne cristata, alba, and C. c. Lemoniana in bloom, together with other pretty species, and a most interesting set of the smaller habited species, among which was noticed the elegant cream-white Maxillaria arachnites, having scores of blooms, M. pumila, the rare M. Houttenana, with reddish-scarlet and white flowers resembling those of M. tenuifolia, but larger, and on a plant of very different habit; M. variabilis unipunctata, and several of the small-habited species, the allied Camaridium Lawrenceanum, of trailing habit, and bearing pretty purple-spotted flowers, &c. Oncidium graminifolium, O. barbatum, and O. chrysomorphum are yellow-flowered species rarely seen in gardens; Cochlioda sanguinea has branched sprays of rose-pink flowers, which open first from the extremity of the inflorescence, and in succession back towards the plant. A pleasing contrast of colour is seen in a grouping of white Odontoglossum pulchellum majus and orange-scarlet Ada aurantiaca and its variety maculata, which is spotted with chocolate purple. A grand example of floral beauty is the large pink and purple Cymbidium insigne Sanderi superbum, which gained a First-Class Certificate at the Royal Horticultural Society, March 3, this year.

In the large Cattleya house are some good varieties of Cattleya Schroderæ and C. Trianæ in bloom; also a fine dark form of C. Luedemanniana, several brightly-coloured Lælio-Cattleyas, three distinct forms of L.-C. Myra, showing great variation in colour, one of them being wholly canary yellow. There were also a fine specimen of an extraordinary variety of Lælia harpophylla, much stronger in growth and larger in the size of its orange-coloured flowers, of which it bears four spikes; two good Oncidium Cavendishianum, and a wonderful specimen of the natural hybrid Brasso-Cattleya Lindleyana, with over 50 white and rose flowers, and some masses of the scarlet Epiphronitis Veitchii, a foot across. All these enumerated are fine examples of good culture. Epiphronitis are rarely seen so fine as those now in flower at Burford, and the good quality of the plants is attributed to their being grown in teak baskets, and suspended in the shady part of an intermediate house, near to the glass of the roof.

A glance through the many other commodious structures devoted to Orchids reveals a very remarkable number of rare species in bloom. In one house is the most complete collection of Cirrhopetalums in any private garden in Europe, some of them being in bloom, including the little feather-lipped Bulbophyllum tremulum. With these is a very fine batch of rare Catasetums, which Mr. White grows most successfully by giving them similar treatment to that afforded deciduous Dendrobiums. They have thus a distinct dry resting season, and a correspondingly moist season of growth, the plants being all suspended. Mormodes and Cycnoches are treated in a similar manner.

In the large intermediate house, in which the Sobralias and taller Epidendrums are grown, the specimens of Miltonia vexillaria are in admirable condition, together with M. Bleuana and M. Phalænopsis. Here the oft-noted specimens of Platyclinis are well furnished with spikes, the largest specimen of P. glumacea having about 100 inflorescences. A brilliant batch of scarlet and yellow Sophro-Cattleyas and Sophro-Lælias give bright colour; pans of two forms of Epidendrum polybulbon were well furnished with bloom, Masdevallia tovarensis, Spiranthes colorata, Epidendrum variegatum, E. Ellisii, E. xanthinum, E. evectum, E. Wallisii, E. Endresio-Wallisii, a fine example of the rose-purple and white Zygopetalum Ballii, Zygo.-Colax Wiganianus, and many others are in bloom, including Cymbidium Woodhamsianum, whose large ivory-white flowers, with some purple markings on the lip, constitute it one of the very finest hybrid Cymbidiums. The Odontoglossums are in splendid condition, some of the good forms being in bloom, including O. crispum, with a few O. Edwardii, the grandly-coloured O. Vuylstekeæ Lawrenceana, and other hybrids. Colour is given by some bright scarlet Sophronitis grandiflora, the chrome-yellow variety of Lælia Cowanii, and rose-coloured Pinguicula caudata. The Masdevallia house has a few plants in flower, and the many forms of M. Harryana are commencing their show of mauve, purple, and scarlet flowers. Two pretty, dwarf-growing, cool-house species here are the white Odontoglossum Oerstedii majus and Sarcochilus Hartmannii. Some showy Cypripediums are also in bloom, a very fine specimen of Lælia rubescens, with many spikes, and various interesting Pleurothallis, Stelis, and other curious species. The raising of hybrids at Burford is restricted to reasonable limits, but there are a large number of hybrid Dendrobiums, Lælio-Cattleyas, Odontoglossums, &c., and already some of these plants have bloomed. *J. O'B.*

ODONTOGLOSSUM ARDENTISSIMUM PEETERSII.

I have received a bloom of this magnificent variety of Odontoglossum ardentissimum from M. F. Peeters. It is a seedling now blooming for the first time, having been raised from the capsule out of which the variety Robsoniæ was obtained. It will be remembered that the variety Robsoniæ bloomed in 1907, and was much admired at the Temple Show held in that year. The photograph of O. a. Robsoniæ, published in the *Orchid Review* for August, 1907, p. 241, will almost serve as an illustration for our present subject if the following details are added:—It is almost identical in form, but is, perhaps, a little less round; this, however, I am not able to perfectly determine, as the bloom was slightly bruised at the margins. O. a. Peetersii is far superior in colour, the intensity of the "port-wine" purple being almost matchless. Two-thirds of the surface of the sepals are covered with this rich colour upon a rosy base, the latter due to the almost entire reverse being violet-purple. The petals are similarly coloured, and in common with the sepals have a pure white margin. The lip and column are similar to those of O. a. Robsoniæ. The bloom has great substance, although developed from a small plant, and partakes much of the characteristic of the crispum parent. This variety will be one of the greatest value for hybridising purposes. It is one of the finest hybrid Odontoglossums, which goes far to prove that the raising of gorgeous garden hybrids is only in its infancy. *de B. Crawshay.*

LÆLIA ANCEPS ROEBLINGIANA.

Mr. Roebling, of Trenton, N.J., U.S.A., has sent me a pressed flower of this variety for description in England. The only reference yet published appears to be one by Mr. Rolfe in the *Orchid Review* for 1898, page 40, and it will therefore be well to describe this remarkable peloriate variety in detail. It must be pointed out, however, that the dimensions have been obtained from a pressed flower, therefore they may be less than those of the actual size, owing to shrinkage of the nerves. The sepals are 2⅜ inches by ½ inch. The colour is pale rose. The petals are 2¼ inches by 1¼ inch at the broadest part, and the lip is 1¾ inch long. The true lip has the usual bright yellow throat and purple nerves. The keel is normal in form and colour. Around its apex is a small, light coloured area, but the rest of the three lobes and margins to the tube are entirely of rich deep purple, similar to that in Lælia anceps as distinguished from the purple of L. Schroderæ.

The two petals flattened out by pressing are indisputably imperfect lips. The lower half instead of being yellow and having a purple margin is of pale rose colour, and, like the sepals, contains numerous nerves, radiating, as in a true lip, to the median distances, some extending to the apex, the central ones being a strong, richly-coloured purple, the remainder being intermittently coloured. At the base there are yellow marks on each side. Where the keel in a true lip usually extends into the purple there is a yellowish white area of exactly the same form, the outer halves of the petals being almost as deep purple as the true lip. It is a very remarkable variety—so far as I know the only case of peloria in L. anceps, and I hope Mr. Roebling will send us a photograph at a future time. *de B. Crawshay.*

NEW OR NOTEWORTHY PLANTS.

ODONTIODA KEIGHLEYENSE

(Cochlioda Noetzliana × Odontoglossum cirrhosum).

Five blooms of this bigeneric hybrid have been sent me by Messrs. J. Charlesworth & Co., Heaton, Bradford. In form the flowers are very similar to those of Odontioda Bohnhoffiæ, they also have a suffusion of mauve in the lower half of both sepals and petals. The influence of the spotting, which is characteristic of O. cirrhosum, is evident as in Odontioda heatonense, but it is less marked, though there is a distinct arrangement of spotting, if I may term it so, by the red being deeper where the spots would ordinarily be found. The intensity of the two shades is unusual, each shining through the other. When the flowers were quite fresh they must have been very beautiful. The lip is almost wholly orange red, having broad side lobes and a narrow apiculate median lobe, which bears a darker blotch at its centre. The four keels are similarly coloured. The column is of the same form as O. cirrhosum, and the stigmas are similar to those of Cochlioda. It is a very small plant, but the flowers possess extremely good colour. *de B. Crawshay.*

THE ROSARY.

CULTURAL NOTES FOR APRIL.

THE heavy rainfalls of last month and the comparatively mild weather that has prevailed since have caused an early growth in all classes of Roses. It is advisable notwithstanding early growth in any year to extend the pruning over several weeks and to delay the final pruning of the Tea and Noisette varieties until last. The pruning of the H.P.s and hardy summer blooming varieties will have been completed by now, and the next to be dealt with are the Tea scented and other tender varieties. A light pruning is preferable to a severe cutting, but all weakly, unripened, and dead wood must be removed, and if the shoots are crowded leave only the strongest of the best ripened shoots, and shorten these back a few inches at their points according to their length. This year the latest pruned bushes will probably give the best results, as the lower buds are only just beginning to swell. Pot plants of Tea and Noisette varieties with long shoots should be carefully turned out of the pots and be planted in the beds with a view to pegging down the growths. All weak, exhausted, and unripe wood should be cut out After well mulching the bed with short manure, a short pointed peg should be secured by tar twine to the point of each shoot. Carefully bend down the growths to within a few inches of the ground and drive in the peg securely. Dispose the shoots equally all over the bed. The following varieties are adapted to this method of training: Duke of Edinburgh, Star of Waltham, Mdlle. Eugene Verdier, Senateur Naisse, Ulrich Brunner, and Mrs. John Laing. Short standard plants growing in central positions or in groups are also very effective when treated in this manner. The best varieties for the purpose are Gloire de Dijon, W. A. Richardson, Carmine Pillar, and Mme. Bérard. Attend to cuttings inserted during the autumn, tread the soil well about them, apply a good soaking of water and a mulch if the weather continues dry. This advice applies to all newly-planted Roses. All earthing or covering up for protection should now be promptly removed, and any damaged shoots be cut back to sound living wood.

Seeds of the seedling Briar should be sown; the hips that were stored in sand or leaf-mould will now be well decayed and the seed is in a suitable condition for sowing. The seed bed should be fairly dry and have been trenched some time in advance of sowing. Draw drills 3 inches deep and 1 foot apart between the rows. After sowing the seed cover up the trenches and make the soil quite firm. It is probable that a portion of the seed only will germinate this year, and it will be a second year before the majority of the plants are well through the ground. The health and vigour of the Rose depends greatly on the character and nature of the soil, and the kind of stock it is worked upon. A good deep sandy loam is most suitable for its cultivation, and where light or sandy soils have to be dealt with, plenty of good stiff loam should be incorporated with it some weeks in advance of the planting season. The Hybrid Perpetual varieties succeed best on the Manetti and Briar stocks; strong growing climbing varieties of the Tea and Noisette sections do best on the De la Grifferie stock. The weaker growing varieties of Teas should be worked on the seedling Briar, whilst the medium and stronger growing varieties succeed on their own roots.

Some of the cuttings of Roses referred to in my last note will now be well rooted, and during this month should be ready for potting. Another hot-bed should be first prepared as directed last month, and when a steady atmospheric temperature of 70° is attained, the best rooted plants should be repotted into 4½-inch pots and be transferred to the newly-made frame where they should be plunged in a thin layer of fibre or fine ashes. If there is an excess of vapour from the fermenting materials, open the back of the frame slightly. Water with tepid water and shade the plants as required. Increase the amount of ventilation as the season advances. Pinch back the longest growths to keep the plants compact and bushy. The first hot-bed should be re-made; this will be used for the remainder of the plants as they are repotted.

The last batch of the forced Roses will now be growing freely, and with the advancing season more ventilation and increased moisture should be given. Care must be taken to prevent cold draughts. Keep the plants well syringed and vaporise the house occasionally to keep down attacks of insects; guard against mildew by painting the hot-water pipes with a solution of soft soap and sulphur. Before the plants have completed their growth and before the flower buds appear, alternate the waterings with weak manure and soot water. Put an equal quantity of manure and soot into a sack and sink the bag in a tub of water a few days before the stimulant is required; add it to half its bulk of clear water before using it.

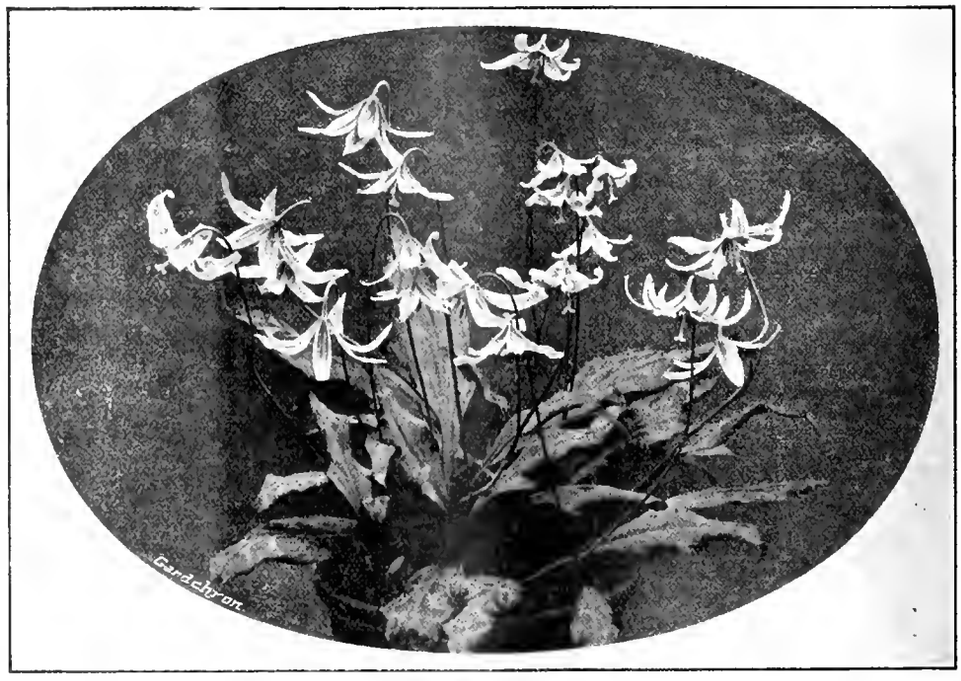
As the grafted plants are repotted they should be placed in a light, well-ventilated house. Afford them a little artificial heat during April and give more ventilation as they become established. These plants are best kept growing under glass till well into May, after which they may be plunged out-of-doors, where they can remain during the summer and autumn months.

Roses cultivated in borders under glass should be given an abundance of water at their roots and mulchings of manure to maintain a vigorous growth. Keep the soil of the borders well stirred and give an occasional light sprinkling of soot and lime to keep the borders sweet and free from insects. An abundance of ventilation should be given on all favourable occasions, leaving the ventilators open slightly at night-time. About the end of April budded plants of last year's raising will require attention at the stocks. All suckers and growths below the scion must be removed, but one or two may be permitted above the dormant bud, to be removed later. Any of the inserted buds that are unduly forward should be carefully secured by a tie. Light hazel sticks may be tied to the stock to prevent the buds becoming broken or damaged by wind. *J. D. G.*

ERYTHRONIUMS.

THE Erythroniums—"Dog's-tooth Violets"—are delightful, spring flowering, bulbous plants, possessing delicately tinted flowers and beautiful foliage. They are easily cultivated and are quite hardy in this country when given the requisite conditions. Erythroniums are naturally woodland plants and they need a certain amount of shade, such as is found in the shady parts of the rock garden, or they may be naturalised on the margins of woodland paths. The most suitable species for planting as wildlings is E. Dens-canis, of which there are many beautiful garden varieties, having flowers of white and purple and many intermediate shades of colour. The Erythronium succeeds best in a deep, rich soil that is composed of leaf-mould and loam; they may, however, be grown with success on comparatively dry, shady banks. The bulbs should be planted deeply and left undisturbed. The plant represented in fig. 94 was cultivated in a pan and was potted in a compost of loam, leaf-soil, and sand. The pans should be placed in a cool, shaded frame and be plunged in ashes to their rim.

With the exception of E. Dens-canis and its variety from Siberia, all the Erythroniums are native of various parts of North America. The genus contains many beautiful and distinct species with intermediate forms, of which the following may be considered amongst the best for garden purposes:—



[Photograph by C. P. Raffill.

FIG. 94.—ERYTHRONIUM GIGANTEUM, AT KEW: FLOWERS LIGHT YELLOW, WITH DARKER CENTRE.

E. GIGANTEUM (fig. 94).—This plant was for a long time known in gardens as E. grandiflorum, but it is distinguished from that species by its leaves, which are mottled with white and brown. It is one of the most robust growing of the genus, excelling all others in height, as well as in the number of flowers it produces. When well cultivated, a single plant often produces eight or ten flowers. These are light yellow in colour, with a darker centre, and sometimes they are margined with brown. E. giganteum is a native of California, and may be planted in suitable situations with every chance of success.

E. GRANDIFLORUM.—This species is one of the most widely distributed of the Erythroniums, being found over the greater portion of North-western America. It has light green leaves that

are quite destitute of mottling, and bears richly coloured yellow flowers. It is rather more difficult of culture than the last-named species, and requires a more shaded position.

E. Hartwegii.—This Californian plant is closely allied to E. giganteum, differing only in its earlier season of flowering and in bearing all its flowers on single stems. The flowers are light yellow in colour with an orange centre; the leaves are richly mottled (see fig. 96).

E. Hendersonii.—This species comes from Southern Oregon, and is one of the most beautiful of all the Erythroniums. It has very handsome foliage and beautiful recurved, light purple-coloured flowers, the petals having a yellow zone or ring near their bases; the centre is of a purple-black colour (see fig. 95).

E. revolutum. This species is widely scattered over the whole of North-western America. There are several well-marked forms, and these include some of the most elegant in the whole family. The type has broad mottled leaves and stout scapes that often attain to a foot in height, bearing light purple flowers. The variety Bolanderi has white flowers tipped with purple. E. r. albiflorum has white flowers with a greenish tinge. One of the most beautiful is E. var. Johnsonii, which has broad leaves mottled with white, while the flower is of a delicate reddish tint with an orange centre.

Besides these there are several other species worthy of a place in the garden, including E. americanum, with mottled leaves and yellow flowers; E. citrinum, resembling E. giganteum, but with an undivided style; and E. montanum, with small pale-coloured flowers. E. Dens-canis var. sibiricum is a handsome variety, with broad foliage and richly coloured flowers. *W. J.*

The Week's Work.

THE FLOWER GARDEN.

By W. Fyfe, Gardener to Lady Wantage, Lockinge Park, Berkshire

Tuberous-rooted Begonias.—For purposes of bedding out, single-flowering varieties are to be preferred, and the tubers should be but one year old. The tubers need to be started in a little heat, and care must be taken at this stage not to over-water the soil on which they are placed. When the tubers have made growth 1 inch in length, the plants will succeed best if placed in partly-decayed leaf-soil in unheated frames. From this material they can be transplanted with good balls of soil adhering to the roots, thus little check will be experienced on their transference to the flower beds. Seedlings should be pricked out into pans or boxes filled with sandy soil, and from these boxes they will need to be again transferred to larger boxes or frames, placing the seedlings at about 4 inches distance from each other in each direction.

Lily-of-the-Valley.—Crowns may be lifted and the roots divided at the present time. If they become overcrowded in a bed, they produce but few flower-spikes of small size. The plant succeeds best in well-drained loam, which is moderately rich and contains plenty of sand. An application of farmyard manure and partly-decayed leaves may be dug into the soil before re-planting. A suitable site is one under the shade of a north or west wall. If the re-planted crowns are expected to flower the first season afterwards, then well-ripened crowns alone should be planted, allowing each crown a space of 3 or 4 inches from each other in every direction. A mulching of fine leaf-mould may be placed over the surface of the ground after planting. During the season of growth, liquid manure may be applied when it is considered necessary. In order to have the flowers pure white, and the inflorescence longer than usual, frames may be placed over the plants a short time before the flowering period commences.

Primroses.—In the pleasure grounds there are always certain positions suitable for Primroses. If Primroses are common in the neighbourhood they may be transplanted into such positions at the present time, or, failing this, seeds may be sown by which excellent plants may be obtained for planting next season. Seeds of Polyanthus should now be sown in boxes, in which case the seedlings will need to be transplanted, or they may be sown in the open borders in drills drawn at 12 inches apart and 1 inch deep. A site under the shade of a north or west wall is suitable. Transplant the seedlings as soon as they are large enough to be handled.

Hardy Ferns.—All species of hardy Ferns may be transplanted at the present time if it is necessary to place them in fresh positions. The common Hart's-tongue Fern (Scolopendrium vulgare), if not too shaded by trees, furnishes excellent fronds of bright shining green, but the plants should be afforded moisture at the roots during periods of drought. The creeping species, such as Blechnum spicant, thrive best when planted in contact with stones, stems of the Oak, and in damp, shaded positions. Polypodiums and Osmundas grow vigorously in a compost of sandy loam, peat, and leaf-mould.

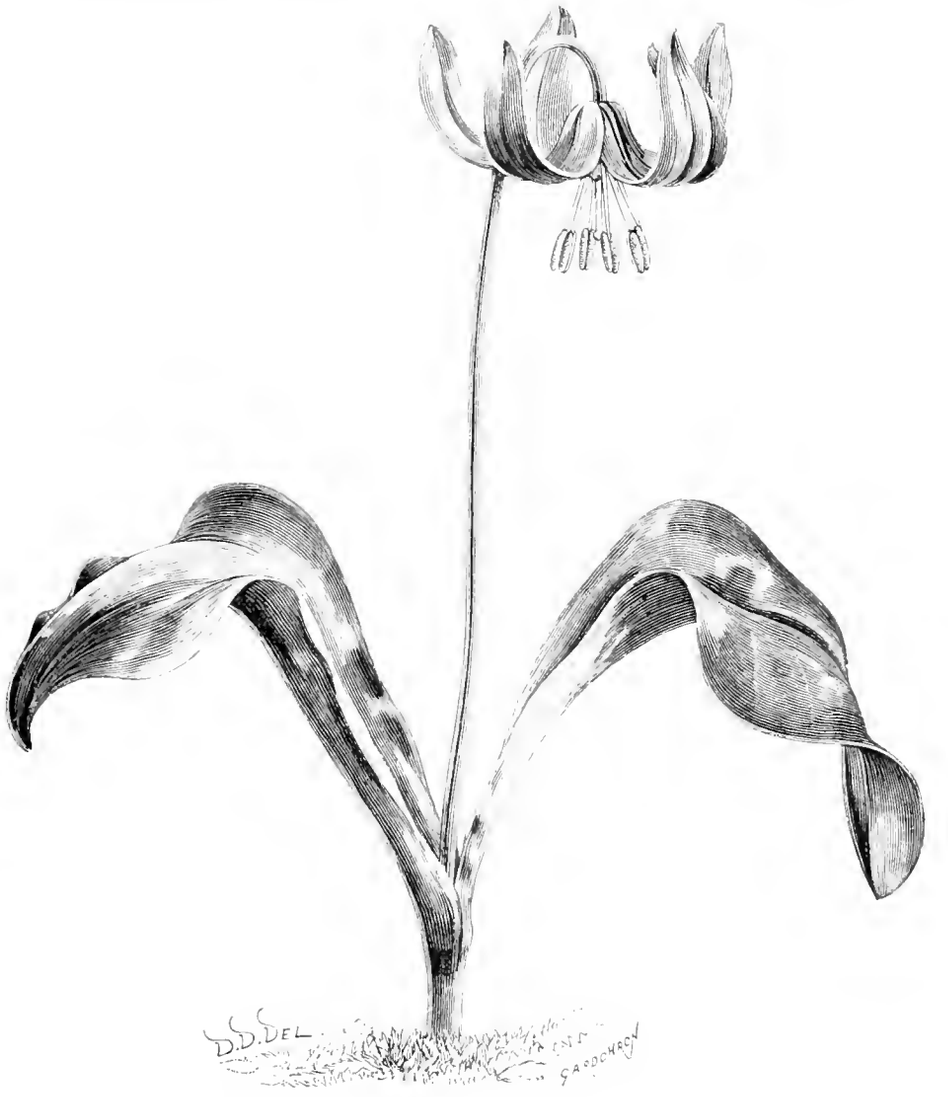


Fig. 95.—Erythronium Hendersonii: colour of flowers light purple, with yellow zone.

THE HARDY FRUIT GARDEN.

By F. Jordan, Gardener to The Dowager Lady Newburgh Holme, Warter Priory, Yorkshire.

Pruning young trees.—Much difference of opinion exists as to when is the best time to prune young fruit trees. Trees that were planted sufficiently early in the autumn to enable them to make young roots before winter are now in a proper condition to support a certain amount of foliage; delay in pruning these would therefore mean a loss of energy by allowing the leading shoots to expand their leaves. The pruning should be done as soon as the sap begins to rise. Shorten any of the leading shoots to about one-third of their length, varying according to the length of the shoot, and otherwise endeavour to shape the tree by removing any shoots that cross each other, being careful always to prune to a point immediately above a bud which points in the direction it is wished the shoot should take. In the case of young trees, six or seven of the best placed branches should be left to form the framework of the trees, cutting back other shoots more or less according to their strength. If the trees are carefully pruned during the first few years, they will not require to be severely pruned afterwards. The centre of the trees should be kept open, and any shoots that form in the centre of the tree after the pruning has been done may be rubbed off. Trees that are not planted until very late in autumn are often left unpruned until the succeeding autumn. This is necessary, because such trees have not had any opportunity of making new roots. Several good waterings should be given to the trees before they show any signs of suffering from drought, as it is sometimes difficult to save them if they are allowed to get into that condition before water is afforded them. Standard and pyramidal Pear trees require almost the same treatment as Apple trees. Plum and Cherry trees need very little pruning, and this only during the first year or two after they are planted.

General work.—Examine all recently-planted trees, and tread the soil firmly around any that may have been loosened by the recent gales. See also that the stakes and ties are in a proper condition and not likely to cause injury to the trees. Lightly fork over the surface ground in the fruit plantations, taking the greatest care not to injure the roots. Lightly prick up with a fork the alleys under the fruit walls, and do not plant any crops within a distance of 3 feet from the wall. The earliest blossoms, such as those of Apricot and Peach, are somewhat late in opening this season, but great care will now be needed to afford protection to the expanding blossoms, especially of Cherries and Pears, in order that they may not be injured by early morning frosts.

PLANTS UNDER GLASS.

By THOMAS LUNT, Gardener to A. STIRLING, Esq., Keir, Perthshire, N.B.

Zonal Pelargoniums for flowering in winter.—The plants that have flowered during the past winter should now be cut back, and the cuttings may be inserted for the purpose of raising plants to bloom next autumn and winter. If it is wished to keep the old plants, the roots must be kept moderately dry until new shoots are formed of about 2 inches in length. At that stage the roots should be shaken out of the old soil and repotted, using for this purpose a compost of loam, leaf-mould, and sand, with a liberal sprinkling of bone meal. In potting, the soil should be firmly rammed round the sides of the pot, for if this is done the plants will be likely to make short-jointed growths that will flower freely. Pelargoniums should never be shaded from the sunshine, except when the plants are in flower. When pinching or stopping the shoots, it should be done immediately above a bud, but care should be taken to see that this is not a flower bud. Pinch off all flower buds that appear during the summer, and until such time as the plants are desired to bloom. Freely ventilate the structure containing the plants, as it is essential the shoots should mature well and harden. Do not apply liquid manures until the plants have well filled the pots with roots. They cannot be given a better place during summer than is afforded by an unheated frame.

Fuchsias.—Plants that have started into growth need very similar treatment to that I have described for Pelargoniums, but they should not be potted so firmly; they will need to be shaded from bright sunshine, and should be given a moist atmosphere. If cuttings are inserted at the present time, they will form roots quickly, and make useful plants for flowering in September in pots 6 inches in diameter. Aged plants are not injured by severe pruning, and these should be placed in a warm house in successional batches, in order that a long season of flowering may be obtained. Keep a sharp look-out for thrips and green fly, and on the first appearance of either of these pests, let the house be fumigated. Pinch off all the flowers whilst the plants are growing, and when it is found the pots have become well filled with roots, apply liquid manure somewhat frequently.

Campanula isophylla.—This plant and the variety alba should now be divided, and the divisions potted up into small pots, when they will be useful for draping the side stages in the greenhouse and conservatory. The plants are likewise very suitable for cultivation in baskets for suspending from the roof of the plant house. They need a rooting medium of loam, leaf-soil, sand, and lime rubble, and during their season of growth should be cultivated in a house of intermediate heat. As soon as the flowers appear, remove the plants to the conservatory or greenhouse. If cuttings are inserted at the present time in a moderate degree of heat, they will soon form roots.

Swainsonia galegifolia.—This species, and the varieties purpurea and alba, are useful plants for training up the sides of a section of the greenhouse. They can be grown quickly, and will cover a large space, although the roots are confined in pots of moderate size. Afford them a compost of loam, leaf-soil, and sand, and apply liquid manure when the pots have become filled with roots. Cuttings made from the young growths will root freely at the present time if inserted in sandy soil on a gentle hot-bed.

FRUITS UNDER GLASS.

By T. COOMBER, Gardener to LORD LLANGATTOCK, The Hendre, Monmouthshire.

Early Peaches.—Until the trees have passed the stage at which the "stones" are formed within the fruits, extra care is needed in the matters of ventilation and heating, that there may not occur fluctuations of temperature. Another factor that might cause the fruits to drop during this critical period might exist if the roots were allowed to suffer either from drought or from an excess of water. Overcropping might have an equally bad effect, but until the fruits commence to swell for the second time, it is advisable to retain upon the trees rather more fruits than will be necessary to constitute the crop. As soon as it is seen that the "stoning" stage is past, take measures to expose the fruits to the sun, using, where necessary, pieces of lath-wood to place underneath the shoots. Continue to syringe the trees on bright days. Such trees as will ripen heavy crops of fruit should be given applications of weak liquid manure, or top-dressings of some quickly-acting fertiliser each time they require to be watered. Train in the shoots and stop such as require to be stopped. If it is found that the shoots have been laid in too closely together, thin out any that are not required. The atmospheric temperature after the "stoning" stage is passed should not be allowed to exceed 65° at night and 70° by day, rising with sun heat (and during the time the houses are freely ventilated) to 85° or even 90°. Close the house early in the afternoon and damp the ground surface to cause abundance of atmospheric moisture.

Strawberries.—Sufficient air may now be admitted to the forcing house to improve the colour and flavour of the fruits without danger of causing any ill-effects. Successional batches of plants should be forced to meet the demands there will be for ripe fruit. To ensure the blossoms becoming perfectly fertilised, even at this season, it will be well to pass a Pampas grass plume or something of the kind over the flowers at mid-day to distribute the pollen. When the fruit has set, thin out the least promising and remove any late blossoms when sufficient fruits have been obtained for producing a satisfactory crop. On no account allow the roots to suffer from want of water, but apply liquid manures at every alternate watering during the time the fruits are swelling, discontinuing such manures immediately the fruit commences to colour. Syringe the plants every day, except when they are in flower or are carrying ripe fruits, and if mildew is feared let the water-pipes be heated unusually hot and painted with a mixture of soft water and flowers of sulphur; or spray the plants with a mildew specific. Plants which still remain in the open should be top-dressed with a rich compost, and be watered as often as necessary.

Early Vines.—As soon as the fruit of such varieties of Grapes as Black Hamburgh, Madresfield Court, and Foster's Seedling, commence to change colour, they may be given an atmospheric temperature of 60° to 65° at night and 70° by day, which may rise with sun heat to 90°. These directions apply to vines cultivated in pots or in borders. By careful ventilation, maintain a freely-circulating, moderately-dry atmosphere during the day and in a less degree by night. Excessive heat would be detrimental to the perfect colouring of the fruit, and much atmospheric moisture in an ill-ventilated structure would probably cause the fruit to split, especially in the case of the variety Madresfield Court. Examine the borders, and if water is required, apply enough liquid manure to wet the soil throughout. If red spider is noticed on the foliage, let the leaves be sponged with soapy water.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Major G. L. HOLFORD, C.V.O., C.I.E., Westonbirt, Gloucestershire.

Temperatures.—The heat of the houses may now be raised a few degrees, owing to the lengthening days, the increasing solar heat and the greater tendency of many plants to make growth. As a general guide the following figures will suffice, observing the higher ones when the weather is mild, and the lower ones when the weather is cold and dull:—**Stove or East Indian House,** by day, 70° to 75°; by night, 65° to 70°. **Cattleya House,** by day, 65° to 70°; by night, 60° to 65°. **Intermediate House,** by day, 60° to 65°; by night, 55° to 60°. **Cool or Odontoglossum House,** by day, 55° to 60°; by night, 50° to 55°. The day temperature, as a matter of course, will vary considerably, and especially in the warmest division the thermometer will now frequently indicate a rise of 10° to 15° on bright, clear days. During such period the fires must be kept well in hand, but the pipes should always be kept slightly warm, so that sufficient ventilation may be given the plants.

Air and moisture.—With the increased heat more moisture may be kept up in the atmosphere, and, therefore, it will be necessary to damp the various surfaces in the houses more frequently. Strict attention should also be paid to ventilation, fresh air being one of the most important factors in the cultivation of Orchids. This should be admitted during the middle hours of the day, by opening the roof ventilators if the outside conditions are favourable, so that most of the moisture of the house may evaporate. The general character of the growth in Orchids which are treated in this manner, that is, if they are kept in a moisture-charged atmosphere during the time the house is closed, and for a few hours after the ventilators are partially opened, is far superior to that which is obtained by admitting a small volume of air to the structure continuously. This daily drying process has the effect of solidifying the growth during its development, and plants so treated invariably make pseudo-bulbs and leaves of a robust and enduring character and have a disposition to flower. The top and bottom ventilators should never be used simultaneously, except under very favourable conditions during the summer months. Admit air through the laths by night on all suitable occasions, and also by day if the climatic conditions prevent the use of the roof ventilators.

Calanthes.—The early flowering kinds will need immediate attention as to repotting. This operation is best carried out as soon as the young growths have attained to a height of about 2 inches. Pot each pseudo-bulb separately, using pots 5 inches and 6 inches in diameter for the strongest bulbs, and smaller sizes for the weaker ones. The pots should be quite clean, and each should be provided with good drainage. Success in the cultivation of these plants largely depends on a proper selection of a rooting medium. The compost that gives the best results is one largely composed of good fibrous loam, two parts, and partly decayed Oak leaves, or chopped sphagnum-moss, one part. A liberal addition of sharp silver sand and broken charcoal will serve to keep the whole porous when the loam is of a heavy character. Let this compost be warmed before it is used, and when repotting keep the base of the pseudo-bulb ½ inch below the rim of the pot. By leaving about 1 inch or so of old roots at the base of the bulb, and pressing the potting material firmly around them, they may be kept firmly in their place until the new roots get a good hold of the soil. Whilst making growth these plants should be given a very light position in the hottest house. No water will be required for some time after the potting has been done, frequent damping between the pots being sufficient until the roots have obtained a good hold upon the compost, when water in small quantities may be applied through a rose can. It is during the early stages of growth that the greater discretion is needed in watering, as a wet soil often has the effect of turning the young growths black.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree, Hertfordshire.

General conditions.—Each day the work in this department will become more pressing, and the gardener will have to be guided by circumstances rather than work by rule of thumb. The nature of the soil, situation, and the condition of the weather, all have important influences. In our case, for instance, after an inch of rain which fell during Wednesday and the early morning of Thursday in last week, we can do little with our soil for at least a week, and yet in other cases where the land is light and porous the soil can be worked on the following day. The most important work, however, is to see that all the crops which have been wintered in frames for planting out, as well as those sown in heat and nursed along under glass, do not become spoilt; at the earliest possible moment after being sufficiently hardened these should be planted out in their permanent quarters. Every care should be taken to keep up a regular supply of the more important vegetables by making frequent small sowings of suitable varieties.

Broad Beans.—As soon as these attain to a height of about 3 inches, they should be planted from the boxes in which they have been raised. Broad Beans require land which has been deeply stirred and well enriched with good manure; on poor, shallow soil, trenches should be prepared much in the same way as for

Fig. 96.—Erythronium Hartwegii: flowers light yellow, with orange-coloured centre.

(See p. 213.)

Celery, and double rows planted in each trench, allowing plenty of room both between the plants and the trenches. Make small sowings in the open garden at intervals of ten days during the next six weeks or so. The long-podded varieties should not be sown later than April, as the Broad Windsors, both green and white, are more suitable for affording late supplies. Plants growing in pots should be kept elevated as close to the glass and ventilators as possible, and when in flower, as they soon ought to be, air must be admitted to the structure by night and day. The points should be pinched off the leading growths after a reasonable number of flowers are showing.

Peas.—These should be planted from the boxes as they become ready. Plant thinly and firmly; apply stakes at the time of planting, and protect the plants against birds. Make a sowing weekly, selecting for this purpose the large-podded and best flavoured varieties.

Onions.—Plants raised in heat that have been pricked off into boxes or pots should now be placed in cold frames to thoroughly harden, and the earlier these can be planted during the present month, provided the conditions are favourable, the better. The Onion is an extremely hardy plant, and if the plants have been kept for a time in cold frames, the weather after this date is not likely to injure them. It is assumed that the land was properly treated during the winter months. Choose a dry day and prick over the surface soil, at the same time giving a good dressing of soot and lime. After two or three days have elapsed, rake down finely, mark out the beds and plant in rows from 15 to 18 inches apart, allowing a distance of one foot from plant to plant.

Seeds.—Sow small quantities of seeds of Brussels Sprouts, Broccoli, Cauliflower, and Borecole. The main sowings should not be made until ten days or so later.

THE APIARY.

By Chloris.

Feeding.—There are many points to be taken into account in determining when feeding should commence. There is the weather and the supply of pollen (the natural supply, I mean), for it is not safe to commence stimulative feeding until the bees are carrying home good loads of pollen. In many cases it is not necessary to feed, but most beginners will feed, whether it is necessary or not. If the bees have sufficient food to supply all their wants, bruise some of the cappings if you like, but give no syrup.

Queenless Hives.—It will not be safe to assume that, because a stock has no brood, therefore it is queenless, for the weather has been so cold at night, and in the day, too, many times of late. When a colony has been discovered to be queenless, and is worth caring for, remove it gradually to another stock headed by a queen. Move both hives towards each other about 1 yard a day (counting days only when bees are on the wing). When the hives are side by side, smoke both lots and give them an opportunity to gorge themselves; remove all combs not covered with bees and replace by frames covered with bees. If a very little warm syrup be poured on the combs, it may assist in bringing about a peaceful union.

Manipulation.—At this season of the year, every time we open the hives a great amount of heat escapes, which must be regained, and this retards breeding and chills much brood. No matter what the outside temperature, that inside must be between 90° and 100°. Even when the outside temperature is not low, the hives ought not to be opened unnecessarily.

Bee dress.—Beyond a veil nothing else is necessary. Some wear gloves, but it is not wise, for they lead to clumsy handling of the frames when replacing, and the jarring thus caused irritates the bees and stinging soon commences. The scent of the poison is retained by the gloves, and this seems to anger the bees very much. If you like you may wear a pair of elastic bands on the wrists to hold down the coat sleeves. If one's movements are not hurried, and the smoker used, but not abused, then there is small likelihood of being stung. I have known men at work among bees for hours and there has not been the slightest disturbance in the apiary nor has the operator suffered from stings.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see*

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, APRIL 4—
Soc. Franç. d'Hort. de Londres meet. German Gard. Soc. meet.

TUESDAY, APRIL 7
Brighton Spring Fl. Sh. (2 days). Cornwall Daffodil and Spring Fl. Soc. Fl. Sh. at Truro (2 days). Nat. Amateur Gard. Assoc. meet.

WEDNESDAY, APRIL 8—
Liverpool Hort. Assoc. Spring Fl. Sh. (2 days).

FRIDAY, APRIL 10—Exeter Daffodil and Spring Fl. Sh.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich 46·1°.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, April 1* (6 P.M.): Max. 53°; Min. 38°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, April 2* (10 A.M.): Bar. 29·9; Temp. 52°; *Weather*—Overcast.
PROVINCES.—*Wednesday, April 1* (6 P.M.): Max. 52° Cornwall and Ireland S.; Min 44° Lancaster.

SALES FOR THE ENSUING WEEK.

MONDAY AND WEDNESDAY—
Sale of Bulbs, &c., at Stevens' Rooms, King Street, Covent Garden, W.C.

MONDAY AND FRIDAY—
Hardy Plants and Bulbs, Perennials, &c., at 12; Roses at 1.30; at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

WEDNESDAY—
Border and Herbaceous Plants, Bulbs, Lilies, &c., at 11.30; Roses and Fruit Trees at 1.30, Palms, Azaleas, &c., at 5, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

THURSDAY—
214 cases Japanese Liliums, received direct, and thousands of Hardy Bulbs, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

THURSDAY AND FRIDAY—
The "Vine House" collection of Orchids. Sale of selected plants at Vine House, Hashingden, Lancs., by order of A. Warburton, Esq., by Protheroe & Morris, at 12.30.

FRIDAY—
Imported and Established Orchids in variety at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

Political Recognition of Horticulture.

The year 1908 will long be remembered as marking an epoch in the annals of horticulture in Belgium. Even the approaching quinquennial show to be held at Ghent, important as it is rightly considered to be, must be regarded as outranged by another event of lasting and truly national significance. It has just been decided by the Chamber of Representatives to widen the Department of Agriculture by the establishment within it of a special Sub-Department of Horticulture, thus securing for horticulture that recognition which it so thoroughly deserves as one of the great industries of the country. The claims for State recognition are the stronger the more closely they are examined, for not only is horticulture a source of profit to the community, but its influence on national life is more far-reaching than might be supposed at first sight.

No form of occupation of land yields so large a return per unit of area. Under the modern methods of intensive cultivation it is claimed that a hectare of land (about 2½ acres) is capable of supporting no fewer than ten persons. In order to obtain such a result, of course a certain amount of capital is required to meet the cost of glass, as well as the ordinary expenses of cultivation, but even if we adopt a considerably lower estimate of the return, so as to approximate to average conditions, it would still mean that, from the point of view of the nation, a very large value was being got out of the land. It is also most important to remember that this profit to the community is almost all of the nature of revenue, not a trenching on capital. Coal and iron, when once dug out and used up, represent so much capital actually spent. The supply is not inexhaustible although we often shut our eyes to this patent and highly disagreeable fact. But the value that is to be extracted from agricultural or horticultural land is practically inexhaustible, for it owes its origin almost solely to the incoming energy of the sun's rays. This energy is constantly pouring in during daylight, and it is the business of the horticulturist and agriculturist to turn it to useful account by fixing it in the form of marketable vegetables, flowers, or fruit. The effect of such an operation is definitely to add to the wealth already existing in the country.

The grazier does the same thing in another way when he grows mutton or beef. For an ox, from the point of view we are now considering, merely represents a further stage of the same process, inasmuch as when the animal builds up his tissues out of the vegetable produce, he is only concentrating still further the energy which the plant has already extracted from the sun during the course of its own growth. But it is obvious that the farmer cannot work so economically as the gardener, for the latter is able to raise a great deal more valuable produce from a limited area than the former could hope to do.

There is another side to the subject, and one of no less interest from the point of view of the public welfare. Horticulture can, nay must, employ a relatively large number of people on the land actually occupied. This circumstance at once causes the industry to assume an aspect of importance in countries such as Belgium or Britain, where on all sides complaints are heard of rural depopulation and the overcrowding of urban districts. The high prices obtained for well-grown or early vegetables and fruit ought to mean, if the producer gets his fair share of the profits, a flowing back of capital to the country, thus rendering its intensive cultivation still more attractive because more remunerative. In this way the wealth accumulated in the city should play its part in encouraging the further development of a rural population. Whether or not such a result is actually achieved, depends largely upon whether the producer is getting a fair proportion of the profits of his skilled labour. One of the important administrative duties that must lie before a Department of Horticulture is to see that the grower is not left in the lurch, confronted by avoidable obstacles that have been interposed between himself and the consumer.

On grounds of political, as well as on those of rural economy, the Belgian Government is to be congratulated on having been the first to take the important step of inaugurating a department, the business of which is to promote these important interests. The needs of horticulture are by no means always covered by, or identical with, those of agriculture. They require independent and expert attention, and we may feel assured that the enlightened spirit which has led to its formation, will see to it that the officers of the new Department are selected for their special capacity and aptitude for dealing with the numerous scientific, economic, and administrative problems that affect the industry in question.

The Government of the United States has already afforded a splendid example of an energetic department that, by its untiring activity, has rendered, and continues to render, services of incalculable value to the landed industries of America. It may be that some day we shall ourselves endeavour to follow the lead of those countries that have realised, more fully than we do, the paramount importance of fostering rural industries, not only on the grounds of their cash value, but also for the sake of their bearing on the welfare of the nation. We continually hear a great deal of talk about rural depopulation, but many people still fail to recognise that, in these days of international competition, when the means of transit have become so easy, so rapid, and, under certain circumstances, so cheap, the problem has ceased to be one depending solely on mere local conditions.

In order that the producer may reap the reward of his skill, and find inducement to make still further efforts, he should be assured of the prospect of getting a reasonable return for his labour. The diffusion of useful information and knowledge, and the rendering of the best scientific assistance, must be further supplemented by the removal of unfair obstacles of all kinds. For these tend in effect to raise the cost of production, and it must be remembered that in a competitive market it is not the consumer nor the middleman, but it is almost always the producer, who is saddled with the unfavourable difference.

We import every year an enormous and increasing quantity of vegetables and fruit. Some of this produce could perhaps never be advantageously raised at home, but it is due to causes which are at least in part preventable that much of the remainder can still be more cheaply bought from abroad.

Manna.

The name of Manna is given to so many different plant exudations, mostly of a similar nature, that it is difficult to define what is really intended when using the common name only. It is well known, however, that the source of commercial Manna is the Manna Ash (Fraxinus Ornus), a native of Sicily and Southern Italy, and not unknown in this country as one of the most graceful and beautiful cultivated trees, especially when in flower. The late Daniel Hanbury, a great pharmaceutical botanist, paid considerable attention to the history and sources of Manna, visiting the plantations in

Calabria and Palermo. In one of his published papers on the subject he gave the following recapitulation of points in the history of the substance, gathered from his own researches, namely, that the Manna known in Europe in very early times was probably all of Oriental origin, and that the Manna of the Ash (Fraxinus Ornus) began to be collected in Calabria in the first half of the fifteenth century; further, that the practice of making incisions in the tree in order to promote the exudation was not commenced until about the middle of the sixteenth century, previous to which period the only Manna obtained was that which exuded spontaneously. Hanbury also states that although the existence in Sicily of a mountain called by the Arabic name Gibil-manna, or Manna Mountain, would seem to indicate that Manna was collected during the period of Mussulman rule in that island (A.D. 827 to A.D. 1070), evidence has not been produced to prove the fact; but that, on the contrary, it appears that Manna was gathered in Calabria long before its collection in Sicily.

Though Manna at the present time does not hold an official position in the Pharmacopœia, it is still used as a mild laxative medicine, and as such the cultivation of the tree in Southern Italy has recently attracted some special attention, and the following interesting details on the mode of collection and preparation for the market have recently appeared. At the age of ten years the tree yields its first crop and continues to give a supply for ten or fifteen years in succession. It is then pruned and left to rest for six or seven years, when it is again tapped and continues to give a further annual supply for another ten or fifteen years, and this system is continued till the tree attains the age of from 80 years to 100 years. The method of collecting the Manna is by making incisions horizontally through the bark of the trunk and lower part of the branches. The Manna flows slowly from these cuts and solidifies by exposure, after which it is carefully removed, and these first exudations are considered the best and purest Manna. A second quality is obtained by a further exudation, which is scraped off when it solidifies, and so it often contains small portions of bark and other impurities. In order to obtain what is known as "tear" Manna, the incisions are made in a slanting direction, into which pieces of straw are placed, and down which the juice trickles and becomes incrusted. Another form of collecting the sweet juice is shown by some exhibits in Museum No. 1 of the Royal Gardens, Kew, in which a leaflet of the tree itself is stuck into the slit in the trunk, and below it is placed a joint of an Opuntia, which forms a kind of basin into which the flowing juice is conveyed by the Ash leaflet. In Southern Italy "tear" Manna of the best quality is said to realise as much as £4 per kilogram, and inferior qualities £2 and £1 respectively. About 4,500 trees occupying a hectare of ground will produce 90 kilograms of Manna, giving a net return of £80.

A large proportion of Italy's export of Manna is said to be converted into Mannite, the process of manufacture of which is reported to have become very much cheapened of late, and in this form much of it is returned to Italy.

Our Supplementary Illustration.—The varieties of Lælia anceps play a most important part in the display of flowers in the springtime in the collection of Major G. L. Holford, C.I.E., C.V.O., at Westonbirt, Tetbury, so well cultivated by Mr. H. G. Alexander, who is writing the weekly article on Orchid culture in these pages. The variety Sanderiana, which has pure white flowers, with some rose-crimson coloured markings on the lip, is found by Major Holford to be the most satisfactory of the white forms by reason of the profuse manner in which it may be made to produce its flowers, provided the specimens be kept in a vigorous condition. Our Supplementary Illustration shows a good example of Lælia anceps Sanderiana, and it may be seen from the illustration that Mr. Alexander's object has been to cause the plant to make the greatest possible number of leading growths, which, when well grown, produce a proportionately large number of flower-spikes. To bring this about, the rhizomes of the back pseudo-bulbs are severed behind each two or three leading bulbs, causing them to produce new growths from the back pseudo-bulbs, and thus in time double or treble the flowering capabilities of the plants compared with those which are allowed to grow on continually from the leading growths alone. The plants are grown in teak-wood baskets, in an intermediate house, and are either suspended from the roof or elevated well up to the light. Lælia anceps Sanderiana was imported from Mexico about 21 years ago by Messrs. Sander, and its introduction was an important event, as its class was only represented by the then rare L. a. Dawsonii. Messrs. Sander's importation also included a quantity of L. a. Stella, a white variety with only a faint tinge of rose on the lip. This, which may be regarded as a form of Sanderiana, is also very beautiful at Westonbirt, where a general collection of the best-named varieties is also grown, the best white forms, besides the above named, being alba, Schroderiana, and Waddonensis. Very handsome coloured forms are Chambe lamiana, which is the largest variety of typical L. anceps; Amesiana, Schroderæ, and Veitchii.

The Royal Gardeners' Orphan Fund.—The festival dinner of this Fund, which will take place on May 12, at the Hotel Cecil, being the "Coming of Age" Festival, it is hoped that all will do their best to raise as large a sum of money as possible. Like all similar institutions the Royal Gardeners' Orphan Fund obtains its principal support from the money raised in connection with its annual festivals, and although it is highly desirable that every effort should be made to increase the number of annual subscriptions in view of present circumstances, it is the bounden duty of every one to make the coming festival an unprecedented success. The entire cost of management is more than defrayed by the dividends from investments, and therefore every penny that is contributed is available for assisting gardeners' widows and orphans. The Duke of Bedford, K.G., who is president of the Fund, will preside at the festival, and the following gentlemen have consented to act as stewards and will be glad to receive subscriptions for the chairman's list:—W. Alderson, Hersham Road, Walton-on-Thames; W. Y. Baker, Thames Bank Iron Co., Upper Ground Street, S.E.; George H. Barr, 11, 12, 13, King Street, W.C.; W. Bates, Cross Deep, Twickenham; William Bull, 536, King's Road, Chelsea, S.W.; G. Caselton, Garden Superintendent, Crystal Palace, S.E.; H. J. Clayton, Wharfe Bank House, Ulleskelf, York; Geo. H. Cuthbert, The Nurseries, Southgate, N.; W. H. Cutbush, The Nurseries, Barnet, Herts.; C. Dixon, Holland House Gardens, Kensington, W.; W. Howe, Park Hill Gardens, Streatham Common, S.W.; D. Ingamells, 27, Catherine Street, Covent Garden, W.C.; John Lyne, Foxbury Gardens, Chislehurst; H. B. May, Dyson's Lane Nursery, Upper Edmonton; J. F. McLeod, Dover House Gardens, Roehampton, S.W.; J. W. Moorman, Superintendent, Victoria Park, E.; Whitpaine Nutting, 106, Southwark Street, S.E.; Edward Parsons, Fruit Market, Covent Garden; R. Hooper Pearson, 40, Brocklebank Road, Wandsworth, S.W., and *Gardeners' Chronicle* Office, 41, Wellington Street, Covent Garden, W.C.; W. Poupart, Marsh Farm, Twickenham; W. Roupell, Harvey Lodge, Roupell Park, S.W.; G. Reynolds, Gunnersbury Park Gardens, Acton, W.; T. W. Sanders, 124, Embleton Road, Lewisham, S.E.; Edward Sherwood, 152, Houndsditch, E., *Treasurer*; David W. Thomson, 113, George Street, Edinburgh; W. P. Thomson, 25, Pollo Lane, Chiswick, W.; Harry J. Veitch, V.M.H., Royal Exotic Nursery, Chelsea, S.W.; and J. H. Witty, St. James's Villa, Swain's Lane, Highgate, N. Those who feel thankful for the wonderful success that has attended the Fund during the past 21 years cannot show their appreciation in a better manner than by sending donations or subscriptions to any of the above-mentioned stewards, or to the Secretary, Mr. Brian Wynne, 30, Wellington Street, Strand, W.C.

Flowers in Season.—We have received from Mr. F. Stokes, of Cokethorpe Park Gardens, Witney, Violets of extraordinary quality. Accompanying the flowers were several photographs showing the plants growing in frames and in pots, but as these were similar to those we published from Mr. Stokes in our issue for January 12, 1907, pp. 28-29, we do not reproduce them. However, they demonstrated how successful a cultivator of these flowers is Mr. Stokes, and the beautiful bunches we received were further evidence of his skill in this direction. Mr. Stokes writes: "I am sending you a few blooms of six varieties of Violets. I should be glad to know if you have any record of finer blooms. The photographs were taken on March 9. The white Comte de Brazza does well in these gardens, although some persons find it difficult to cultivate, as it does not always develop such good flowering crowns as do most other varieties. The colours of the old Neapolitan and Lady Hume Campbell are much alike: they both do well here, and I experience very little trouble with damping during the dull, short days. The varieties Marie Louise, J. J. Astor, and Coolcronan are the most liable to suffer from damping. The pot plants shown in the photograph are growing in 6-inch pots, the varieties being Neapolitan and Lady Hume Campbell. These pot plants have been continuously in bloom since the end of October last."

Strength of Timber as Influenced by Moisture.—Some interesting information dealing with the influence of moisture upon the strength of different kinds of timber, says the *Agricultural News*, is contained in a pamphlet recently issued by the Forest Service, U.S. Department of Agriculture. From a consideration of the particulars given it is at once evident how very different degrees of strength may be given to two boards of the same piece of timber by different methods of seasoning. One of the first results of the seasoning of wood is the evaporation of the moisture contained in the interior of the individual cells. This naturally lessens the weight of timber, but it is not until the moisture in the substance of the cell-walls themselves begins to evaporate that the strength of the timber is affected. When the cell content of water has evaporated, but the moisture in the substance of the cell-walls is still present, the wood is at what is known as "fibre saturation point," and from this stage to

absolute dryness there is a remarkable gain of strength in the wood. Exposure to atmospheric conditions may bring about a re-absorption of moisture, but still if proper seasoning has taken place, most woods remain from 50 to 150 per cent. as strong as when in the green condition. The importance of care in seasoning timber is therefore at once evident.

STUDIES OF KEW GARDENS, &c.—Many people having expressed a wish to see the portraits of native princes of Central India, which are destined for the Daly College, Indore, the Grafton Galleries, Grafton Street, Bond Street, has been taken for their exhibition from Monday, April 6, to Wednesday, April 15, hours 10 a.m. to 6 p.m. At the same time there will be shown a collection of studies of Kew Gardens, together with some Italian landscapes and other works, also by HERBERT A. OLIVIER.

FLORA OF NEW SOUTH WALES.—We have received the first part of *The Illustrations of New South Wales Plants*, by J. H. MAIDEN, the indefatigable Director of the Botanic Gardens, Sydney. Eleven plants belonging to various natural orders are figured and described, and notes of the distribution of the species, so far as it is known, are also incorporated. Sometimes these are rather humorous, *e.g.*, it is said of Sprengelia ponceletia, an epacrid, that its known range will be extended by careful search, "especially as swamp-loving plants are often avoided by those botanists who are afraid of getting their feet wet." The illustrations are good, and in addition to a figure of a characteristic branch, with the flowers, dissections of the flower and fruit are also depicted.

A CLIMBING ACONITE (A. volubile latisectum) has been introduced from China by Messrs. VILMORIN, ANDRIEUX ET CIE, Paris. The foliage is deep green, and the blue flowers continue to be produced until the autumn frosts. The plant climbs to a height of from 6 to 7 feet, and is suitable for a trellis.

A SCENTED DAHLIA.—Herr T. C. SCHMIDT, of Erfurt, has introduced a Dahlia, which is characterised by a sweet scent recalling that of honey. The plant originated from Mexico, and is said to be of good habit. Planted out in May, it flowers in July and August, the blooms being of a shade of orange-scarlet, and borne on long stems, thus rendering them very suitable for use as cut flowers. The plant reaches a height of 4 or 5 feet.

SUNFLOWER SEEDS.—The Sunflower is grown in many parts of the world for the sake of the oil in its seeds. The yield of seed varies a good deal according to variety, soil, and climate, but about 1,500 lbs. per acre seems to be a fair average return, and in South Africa as much as 3,250 lbs. per acre has been recorded. About 15 to 20 per cent. of oil can be obtained from the seed, and it is used for many purposes, the better qualities being sometimes employed in cookery. The seeds themselves, when stripped of the fruit husk, are eaten as food after being parched, in some regions—for example in Russia—and they are also used both in the fresh state, and after the oil has been expressed from them, as food for poultry.

* **"THE PRACTICAL GREENKEEPER."**—Mr. REGINALD BEALE is the manager of Messrs. CARTER'S golf department, and the hints he gives in this little booklet cannot but be useful to those who are responsible for maintaining turf in good condition, whether in the garden or on the links. Excellent instructions are given as to the treatment of different classes of soils, and also as to the choice and mode of application of manures. Copies can be obtained gratis from the publishers.

* Published by James Carter & Co.

EXTERMINATION OF LOCUSTS AND DODDER.—An interesting method of exterminating locust swarms is given by a writer in a recent number of the *Agricultural Journal of the Cape of Good Hope*. Young grass was cut up and soaked in 5 gallons of water containing 1 lb. of sodium arsenite and 4 lbs. of sugar in solution. If the locusts are fully grown, a stronger solution is used. The poisoned grass is scattered thinly about the bushes on which the locusts were resting during the night. It is stated that the insects at once feed on the sweetened grass, and are soon entirely destroyed. Arsenite of soda, 1½ lb. to 5 gallons of water, is also said to afford one of the best means of killing dodder on Lucerne. It is sprayed on the plants, and seems in no way to injure the Lucerne.

Publications Received.—*A Practical Guide to School, Cottage, and Allotment Gardening*, by J. Weathers. Published by Longmans, Green & Co.—*Twenty-fifth Annual Report of the Metropolitan Public Gardens Association*, being the report for the year 1907. Published at 83, Lancaster Gate, London, W.—*The Law of Master and Servant*, by James Walter Smith, LL.D., revised by George Frederick Emery, LL.M. This volume is one in the series of "Wilson's Legal Handy Books," and is published by Effingham Wilson, 54, Threadneedle Street, London, E.C.—*The Wild Rabbit* or *Rabbit Warrens*, combined with Poultry Farming and Fruit Culture (3rd edition). By J. Simpson, published by Messrs. Pawson & Brailsford, Sheffield.

THE ALPINE GARDEN.

SHORTIA UNIFLORA.

AMONGST the many interesting plants at present in flower at Kew is the beautiful Shortia uniflora (see figs. 97 and 98). Rare in gardens till recently, it was considered by some to be identical with the better-known S. galacifolia from North Carolina. The Japanese species, however, is quite distinct, although the foliage of the larger forms is very similar to that of the North American one. During the last year or two it has been more freely imported from Yokohama, and has now become more plentiful in cultivation. There are now two distinct forms in flower, one with small leaves somewhat resembling those of Schizocodon soldanelloides, and pale-coloured flowers; while another, recently received under the name of Shortia uniflora var. grandiflora, has much larger foliage, like Shortia galacifolia, and deep rose-coloured flowers with a paler centre. While capable of thriving outside in a peaty bed, with a northern aspect, in the rock garden, it is not seen with such advantage as when grown in pans in a shady frame and shown in the cold greenhouse when in flower. The Japanese species may be readily distinguished from the North American representative of the genus by its flowers, which, when fully expanded, are nearly flat, compared with the funnel-shaped flowers of S. galacifolia. It is also some two or three weeks earlier in coming into flower. A native of Japan, it is usually found growing in dense forests of Coniferæ, at an elevation of about 2,000 feet. An evergreen creeping plant, the persistent leaves are toothed, and assume in the autumn the rich tints that are so attractive in the other better-known member of this genus, as well as in Schizocodon. *W. J.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

THE CULTIVATION OF THE CLEMATIS.—Mr. Harold Evans, in the issue for March 14, p. 173, solicits information regarding the successful culture of the Clematis, and particularly of the hybrid varieties. I have propagated and cultivated many thousands of these plants, had many failures, and made many diverse experiments. The principal causes of the failure of these plants when young, are in faulty potting, planting out, and cultivation, and not, as is generally supposed, in their grafting. When the graft has started into growth, the portion of the stem where the stock and the scion are joined should not be imbedded in the soil, and when shifting the plants into larger pots this junction should be raised 2 or even 3 inches out of the soil to fully expose the union of the graft, that it may become hardened, and thus form a woody texture. The practice should be the same in this respect, whether the graft be made of one-year-old wood or of new growth of the current season. Upon receipt of the plants from the nurserymen, it will be seen whether they are potted deeply, and if so the surface soil should be immediately removed in order to harden the graft. No roots will be found in the upper part of the pot, for the Clematis never forms surface roots, but they descend deeply into the ground, and this is clearly seen on removing a plant from a pot, it will then be found that the majority of the roots are in the drainage materials. After the hardening process is complete, and this usually occupies three or four months, the plant will be ready for transplanting to its permanent quarters, or to be potted and grown as a specimen plant. Deep cultivation is essential in the case of ground intended for the reception of these plants. The soil in the border or bed must be stirred to a depth of 3 feet, and have incorporated with it leaf-mould or well-decayed manure from a spent Cucumber bed, sand or fine gravel, and a goodly proportion of finely-broken, soft, red brick. Care should be taken that lime or mortar rubble in the smallest quantity is not present in the soil, as this constituent is most harmful. Allow a few days to elapse in order that the soil may settle down before planting, which should be done as near to the surface of the ground as is possible: at least 3 inches of the stock should be seen above the surface of the soil. A piece of zinc or tin 2 or 3 inches wide should be placed around the stem of the plant, but not close to it; a space should be allowed as far from the stock as the rim of a 5 or 6-inch pot would be if the plant were placed in a pot of this size. The metal band will prevent soil from the border working up around the plant and burying the union of stock and graft. I have proved by experience that the principal cause of failure with the Clematis is deep planting, instead of deep cultivation. With reference to plants already in position, and not in a thriving condition, I recommend that the soil be removed from around their stems in the form of a basin. Place a piece of zinc around the stem to keep it exposed, and top-dress the border with decayed manure. Specimen plants growing in pots must not be potted deeply; the stock should be exposed at least 2 inches. Deep pots of the "Long Tom" pattern should be used, and each season the plants should be given a top-dressing of some good soil, containing broken soft, red brick, with a little Ichthemic guano. Watering is an important matter, and Clematis planted in borders against dwelling-houses often become dry at their roots They should be attended to regularly, and be sometimes fed with weak liquid manure. *John Smith, Messrs. Keynes, Williams & Co., Nurseries, Salisbury, Wilts.*

RHODODENDRON COUNTESS OF HADDINGTON.—I have always understood that this fine Rhododendron was raised by the late Mr. Lees when gardener to the Earl of Haddington, at Tyninghame, East Lothian, and that it was the result of a cross between R. Dalhousiæ and R. ciliatum. There are probably many still alive who can confirm this statement. But whether Mr. Lees was, or was not, the raiser, there is no doubt at all regarding the parentage of this plant. It is R. Dalhousiæ × R. ciliatum, and not as stated on p. 197: "It is generally supposed to be R. Dalhousiæ × R. Gibsonii." This latter cross produces a very different plant from R. Countess of Haddington. *R. Lindsay.*

MEALY BUGS ON VINES.—Referring to *P. R.'s* query on page 206, I would like him to write to Mr. Dobson, Gardener, Stapleton Park, Pontefract, who, I think, will be able to help him in his difficulty. I know he has done this with others by the use of what you mention at foot of his note, viz., fumigation with hydrocyanic acid gas. Mr. Dobson has more than an elementary knowledge and experience in chemistry in connection with horticulture in general. *Yorkshire Gardener.* [A contribution from Mr. Dobson on this subject was published in the *Gardeners' Chronicle*, February 10, 1906, p. 85.]

Elementary School Gardens.—According to Mr. McKenna's statement (see p. 185) there existed last year 1,138 groups of school-gardens in England and Wales. It is, therefore, not unfair to assume that, taking an average number of 15 boys under tuition in each centre, there were upwards of 17,000 pupils receiving instruction in elementary gardening. In the county of Surrey, with its 80 groups of gardens, the total number of separate plots and scholars was last year 1,295, or an average of about 16 plots per group. But the number of plots vary from as low as 9 in a small school to 42 in a large one. This Surrey return, however, does not include gardens in certain areas where the Education authorities are other than the Surrey Education Committee. In the Borough of Kingston-on-Thames there has been for two years one centre of 28 gardens, and a group of the same number has just been created as a second school. Head teachers of all the elementary boys' schools in this town greatly desire to have such gardens also, but their desire is hindered by lack of ground and by the inertness of their managers. That the movement will extend is certain. Necessarily the instruction given is of a very elementary kind and is largely limited to vegetable culture. Where sufficient ground is available, fruit, flower, and special practice or experimental plots are also included, but generally vegetables constitute the staple products cultivated. When the gardens range from half a rod to a rod in area only, it is obvious that the range of products grown must be limited also. The instruction is either given by the school teachers, many of whom are enthusiastic gardeners, or by professional instructors, and includes trenching, digging, hoeing, manuring, marking out plots in mathematical order, drawing drills, sowing seeds, thinning crops, planting Potatos, staking Peas and Beans, and generally maintaining each plot in a high degree of neatness. Necessarily these operations include instruction in the proper handling and use of tools, including the spade, fork, hoe, dibber, &c. The work also furnishes the pupils with a practical knowledge of the discipline of labour. The Education Department makes a grant of 4s. per head where the work of instruction is well done, and these sums naturally help to recoup the outlay incurred in providing tools, manures, and seeds, as well as the fees of professional instructors; hence the expense incurred by the local authorities is light. In some cases the boys are given the crops they produce, or they are charged a small sum for them, and thus they are induced to work well to secure the best possible value. It is unwise to assume, as has been hastily done, that the boys thus instructed will ultimately enter the ranks of professional gardening. Should a few do so, they would doubtless prove to be much more useful in gardens at the outset than would lads who have had no garden training. There are many fields open to these youths as they grow up, to develop their gardening knowledge. As amateur gardeners, cottagers, allotment holders, or possibly as tenants or owners of small holdings, they may, in their manhood, find their school experience and tuition of great value. Few things would be more advantageous to horticulture than that the amateur and cottage gardener should be increased by tens of thousands. There is ample room for them. Millions of acres of good land now producing comparatively limited crops under agriculture, could be made trebly productive under garden culture. But, it may be asked, if all this is being done for boys in elementary schools, why is not something equally useful provided for girls? School authorities so far have limited girls' garden activities to what is described as Nature study. That is very pretty work, and is very interesting, but it lays the basis of no future vocation for girls, as gardening does for boys. Would girls take to gardening? If we are to judge of what is being done by young women at Swanley, Reading, Studley Castle, and at other horticultural colleges or centres, their claims cannot be ignored. Why should not girls have their plots also, and be allowed to commence with the growing of flowers? The girls in our country schools are sturdy, robust, and strong enough. They have the same capacity to dig and delve, to sow and cultivate gardens as have boys. Therefore, why not gardens for girls? If they want to fight the battle of life in their own way, let them have equal opportunities to the boys. Let us hear no rubbish about gardening unwomaning woman. It is nonsense. Whatever a woman can do well, she has the fullest right to do; hence, if she wishes to garden, let her have her chance by all means. *A. D.*

The Black Currant Mite.—Four years ago this pest was first found in these gardens, fortunately on young plants that were isolated from the majority of our Black Currant bushes. Two rows had been planted with separate varieties. Only one row was attacked at first, and in a very mild form. All affected portions of the bushes were cut off and burned, and the bushes were sprayed with an insecticide. The following season the plants were not entirely free of the pest, and they were therefore dug up and destroyed by burning. To my surprise the next season No. 2 row showed signs of "big bud" again in a mild form. This time I cut all the affected growths back to one bud and thoroughly examined the remaining growths to make sure they were quite free of the mite, and again the bushes were sprayed. This spring these bushes were covered with affected buds, and they were also destroyed by fire. It may be interesting to state that there are Black Currant bushes, both old and young, planted in other quarters of these gardens that are quite free of "big bud." I am convinced that where this pest shows itself, there is only one course to adopt, and that is to burn the bushes. I am of opinion that spraying with any insecticide that can be applied without injury to the bushes is useless. *Wm. Johnson, Broxmouth Park Gardens.*

Species of Phormium.—There are now many plants of Phormium tenax in Scottish gardens, and the hardiness of this species in a great part of the country has now been so well proved that it might be much more freely planted. Nor should I trouble myself much about the moisture in the soil. A good deal naturally depends upon the rainfall of the district, and in wet parts of the country a less moist position is called for than is necessary in those which have a smaller rainfall. The plants in the Edinburgh Royal Botanic Gardens have been cited as supporting the case for moisture at the roots from their being on the banks of the pond. They do not form, however, a proof that such a situation is the best for P. tenax, as there are much finer plants elsewhere in Scotland than those in Edinburgh, and some that I know well are on dryish soil and with a dry subsoil, and beyond the reach of any special supply of water at the roots. I think, too, that such plants flower more freely than those in a moister position. I have in my own garden a plant which has surprised me by its rapid growth on a dry soil, in what is, indeed, if not the driest almost the driest part of the garden. It is not essential that a Phormium should have access to moisture, but if planted well above it, in a warm and dry position, and their roots can reach the water if required, they flourish well. The plant withstands a wet winter wonderfully well, and I know of some which passed successfully through the most severe and trying winters we have had north of the Tweed within the last thirty years. *S. Arnott.*

Arboricultural Records.—On reading the leading article (p. 200), I am prompted to send you dimensions of what was at that time—1866—a very fine specimen of Abies Douglassi growing in the finely-timbered grounds at Hackwood Park in Hampshire. I went there as gardener that year, and had the measurements carefully taken. Its height was 82 feet, girth at 40 feet from the ground 4 feet, girth at 2 feet from the ground 9 feet 3 inches. The circumference of the branches at the ground level was 123 feet. At that time, and for the six following years, it was a magnificent tree. Not very far from this specimen was a very nice specimen of the Weeping Turkey Oak (Quercus cerris pendula), which is mentioned in Loudon's work. At the time named there were more than one man employed on the estate who remembered the Abies Douglassii being planted, which, I think, was about the year 1824. Perhaps Mr. Bowerman will tell us what condition the tree is in at the present time. In the year 1870, the present owner of Hackwood, Lord Bolton, took some small self-sown seedlings of the Abies to Bolton Hall in Yorkshire. *H. J. Clayton, Ulleskelf, York.*

The Florist's Art.—Once more the time has arrived for Committees of flower shows to frame their schedules for the coming summer. There are many persons, including myself, who when judging cut flowers are in doubt as to some being annuals or perennials; for instance, Gladiolus are sometimes shown in the class for perennials. [Why not?—Ed.] I would like to see greater encouragement given to the cut flower classes, as they are a fine feature at all exhibitions. I would suggest that the prizes be offered under the heading, "Outdoor Flowers," for by this wording an exhibitor can put in any flower so long as it is grown in the open. In the large shows special prizes could still be offered for such special flowers as Phloxes, Montbretias, Pentstemons, Godetias, Michaelmas Daisies, &c. *A. J. Long, Wyfold Court Gardens.*

SOCIETIES.

ROYAL HORTICULTURAL.

March 31.—There was a bright display of flowers at the exhibition held on Tuesday last. Groups of Orchids were not so extensive as at recent meetings, but there were many novelties submitted to the consideration of the Orchid Committee, for they awarded four First-Class Certificates and four Awards of Merit.

The Floral Committee made four Awards of Merit to novelties. The hall was gay with many exhibits of Carnations, which were intended to be shown also at the Carnation Exhibition held in the same building on the following day. There were handsome groups of forced shrubs and trees, displays of Roses, greenhouse flowering plants, Clematis, Rhododendrons, and a wealth of other spring-flowering subjects.

The Fruit and Vegetable Committee recommended an Award of Merit to a variety of Orange.

At the 3 o'clock meeting of the Fellows a lecture was delivered by the Rev. Prof. George Henslow on "The History of the Cabbage Tribe."

Floral Committee.

Present: W. Marshall, Esq. (chairman); and Messrs. Chas. T. Druery, John Green, W. A. Bilney, T. W. Turner, R. C. Notcutt, C. J. Salter, W. Howe, John Jennings, Arthur Turner, Chas. Dixon, Chas. E. Pearson, Wm. Cuthbertson, Chas. E. Shea, W. P. Thomson, E. H. Jenkins, Wm. J. James, George Paul, Herbert J. Cutbush, G. Reuthe, Chas Blick, J. F. M'Leod, and James Ffudson.

Mr. Russell, Richmond Nurseries, Surrey, showed a very handsome group of forced shrubs and trees. The plants were well-flowered, and included Lilacs, Azaleas, Laburnums, Wistaria, Cherries, Apples, Weigelas, including the dark crimson-flowered Eva Rathke and the white candida varieties. The group was completed with an edging formed of small plants of Clematis in flower and the ornamental-leaved Euonymus latifolius. (Silver-Gilt Flora Medal.)

Messrs. James Veitch & Sons, Ltd., King's Road, Chelsea, filled the table they usually occupy, with showy flowering plants, principally of greenhouse species, and at one end of the table was arranged a display of Carnations. The greenhouse plants included a wealth of showy-flowered species. Streptosolen Jamesonii had flowers of a remarkably rich colour, the plants being in small pots. The new Coreopsis Grantii showed to advantage against a background of the pink-flowered Crowea angustifolia. Clianthus puniceus was intermingled with Boronias. Malvastrum grossulariifolium, Primula × kewensis, Rhododendron amœna, R. Veitchianum (magnificently flowered), Primula obconica of an improved strain, and Eupatorium probum are other subjects worthy of mention. The same firm exhibited a group of forced flowering trees and shrubs, with species of ornamental-leaved Vitis. (Silver-Gilt Flora Medal.)

Flowering sprays of several interesting shrubs were shown by Mary Countess of Ilchester, Abbotsbury Castle, Dorchester (gr. Mr. Kempshall). The beautiful rose-coloured Magnolia Campbellii was represented by half-a-dozen magnificent blooms. There were also Aloe ciliaris, Kennedya macrophylla, Acacia verticillata with leaves in whorls, A. trinervis, and Fuchsia serrata.

Messrs. PAUL & SONS, Cheshunt, showed dwarf shrubs and trees, including a golden form of the Scots Fir. They also exhibited flowering sprays of interesting and uncommon subjects, amongst which we noticed Lonicera fuchsioides, Ribes speciosa, Petasites palmata, Astilbe (Spiræa) "Peach Blossom," Cytisus incarnatus, &c. Rose Tausendschon was in company with a new Rose named Amber; the buds of this latter variety are copper-coloured, but the petals are almost white in the expanded flowers.

Winter-flowering Carnations were shown by most of the prominent cultivators of this popular flower. Mr. H. BURNETT, Guernsey, displayed Carnations of a very high quality, including many varieties of his own raising, a prominent positon being afforded the beautiful pink flower named after Mrs. Burnett. Enchantress, Mikado, Winsor, Fiancée, Britannia, Mrs. Lawson, and many others were shown in first-class condition. The arrangement of the flowers left little to be desired. (Silver-Gilt Flora Medal.)

A display of choice Carnations was presented by Messrs. BELL & SHELDON, Castel Nurseries, Guernsey. They were all of well-known varieties such as Enchantress, Aristocrat (cerise pink), Harlowarden (dark crimson), Lady Bountiful (white), Mrs. Lawson (pink), Robert Craig (scarlet), Britannia (scarlet), &c. A groundwork of small ferns with sprays of Asparagus Sprengeri and Smilax gave a pleasing finish to the display. (Silver-Gilt Banksian Medal.)

Messrs. HUGH LOW & Co., Bush Hill Park, Enfield, made a very attractive exhibit with Carnations of the winter-flowering section; pot Roses of the rambler and dwarf polyantha types; Gerbera Jamesonii, and Metrosideros floribunda. The Carnations were displayed in tall receptacles, with shorter vases interspersed, and with suitable greenery. The variety Aristocrat (cerise pink) was noteworthy. There were also fine vases of Mrs. Burnett (salmon pink), Lady Bountiful (white), Enchantress (pink), Victory (scarlet), Britannia (scarlet), &c. (Silver Flora Medal.)

Mr. A. F. DUTTON, Iver Nurseries, Bucks, displayed excellent Carnations in very tall, glass vases. The beautiful rose-pink Enchantress, Beacon (scarlet), Robert Craig, Winsor, and other standard varieties were all well shown. (Bronze Flora Medal.)

Mr. W. H. PAGE, Tangley Nurseries, Hampton, showed vases of well-grown Carnations, arranged on a groundwork of Adiantum Ferns. One of the best varieties in this exhibit was the white "My Maryland." Large vases of Lilium longiflorum were arranged at the back of the exhibit. (Silver Banksian Medal.)

Messrs. H. B. MAY & SONS, The Nurseries, Upper Edmonton, showed Clematis, Cinerarias, Pelargoniums, Roses, and Ferns. The pretty pink, single Rose "Princess Ena" was shown in pots; the large trusses of flowers are remarkable for their longevity. There was also a batch of the dwarf-habited Mme. N. Levavasseur Rose. The Clematis were plentifully flowered, although in small pots; the variety Nellie Moser was especially pleasing. Cinerarias of the ordinary florist's type made a very bright display. The Ferns included many varieties and species of a decorative character; they were interspersed amongst the flowering plants. (Silver Banksian Medal.)

Messrs. SUTTON & SONS, Reading, showed batches of Italian Hyacinths, a type admirably adapted for decorative purposes or for supplying cut blooms. Their season is intermediate between those of the Roman and Dutch strains. They are useful for interspersing amongst other plants in a greenhouse. At one end of the exhibit was a number of Cinerarias, the whole being relieved with Ferns and small Palms.

Messrs. RICHARD SMITH & Co., Worcester, set up a group of Clematis, of which flower this firm makes a specialty. The plants were mostly "balloon" trained; some at the back were supported on neat stakes of bamboo. The edging to the group was very pretty, having as its components Hyacinths, Veronica Hendersonii, Anthurium Scherzerianum, Cytisus, small Acers, and other ornamental-leaved and flowering plants. The varieties of Clematis included Sir Garnet Wolseley (heliotrope, with purple central striping), Mrs. Geo. Jackman (white), the beautiful Nellie Moser, The Queen, President (a finely-formed blue flower), Mrs. Quilter (white), Edouard Desposse, Miss Bateman, C. montana rubens, &c. (Silver-Gilt Flora Medal.)

Messrs. FRANK CANT & Co., Braiswick Rose Gardens, Colchester, showed Roses, both plants and cut blooms. Wichuraiana varieties were staged at the back of the display with Richmond, Mrs. David McKee, Mme. Constant Soupert, Lady Roberts, Gustave Grünerwald, and other well-known varieties in the foreground. (Bronze Flora Medal.)

Very large Roses were shown as cut blooms by Mr. GEORGE MOUNT, The Nurseries, Canterbury. The exhibit was similar to the displays by the same exhibitor at the two preceding meetings. La France, Richmond (red), Frau Karl Druschki (magnificent specimens), and Joseph Low were the varieties shown on this occasion. (Silver Flora Medal.)

Excellent Roses were also shown by Mr. R. FELTON, Hanover Square, London, W., the varieties being Mme. A. Chatenay, Richmond, and Kaiserin A. Victoria. (Silver Banksian Medal.)

Messrs. H. CANNELL & SONS, Swanley, Kent, made another pleasing display with brightly-coloured trusses of Zonal Pelargoniums. The largest-flowered variety was St. Louis; the colour is scarlet flushed with crimson. Others of special merit are Caledonia (pink), Arabic (scarlet), Mauretania (pale colour), Cymric (purple), and Lucania (orange). In this exhibit was a pure white decorative Pelargonium named alba fimbriata. (Silver Banksian Medal.)

Rhododendron flowers in great variety were shown by Mr. R. GILL, Tremough, Penryn, Cornwall. They were principally varieties of R. arboreum, and were all gathered from plants growing in the open. A plant of R. ciliatum was covered with its delicate blush flowers. (Bronze Flora Medal.)

Messrs. R. WALLACE & Co., Kilnfield Nurseries, Colchester, showed interesting and rare Alpine plants with bunches of Tulips and small shrubs at the back. There were Hepaticas in several colours, Anemones, Irises, Saxifragas, and similar subjects in great variety. (Bronze Flora Medal.)

Messrs. WM. CUTBUSH & SON, Highgate, London, N., staged a pleasing exhibit of Alpine and rock-garden plants, with many flowering shrubs. The exhibit was arranged with considerable skill, a free use of virgin-cork being employed so as to imitate a portion of a natural rock-garden. The shrubs, which included Rhododendrons, Magnolias, Staphylea colchica, Spiræas, Amlanchier canadensis, and similar subjects, were arranged as a background to the display. The Alpines included Viola pedata, Arnebia echioides, Tulipa Kaufmanniana, Primula rosea, P. Sieboldii, Trillium erectum, T. sessile "Snow Queen," Ledum latifolium compactum, &c. Messrs. CUTBUSH also exhibited Carnations of the winter-flowering type. (Silver Flora Medal.)

Messrs. JOHN LEED & SON, West Norwood, London, in addition to a collection of seasonable hardy flowers, showed Carnations, Caladiums and small succulent plants. (Bronze Flora Medal.)

Mr. G. REUTHE, Keston, Kent, showed a selection of seasonable hardy plants and trusses of Rhododendrons. (Bronze Flora Medal.)

Mr. A. R. UPTON, Hardy Plant Nurseries, Guildford, contributed a display of seasonable hardy flowers. Primula rosea was especially well shown; we also noticed some good plants of Omphalodes verna with its pretty blue flowers, Soldanella alpina, and a specimen of the shrubby Andromeda calyculata, the small flowers being solitary in each axil, but forming collectively long racemes.

Messrs. T. S. WARE, LTD., Feltham, Middlesex, showed rock-garden and other hardy-flowering plants in variety. We noticed a fine pan of

FIG. 97.—SHORTIA UNIFLORA, A SPECIES WHICH GAINED AN AWARD OF MERIT AT THE R.H.S. MEETING ON TUESDAY LAST.

Narcissus Bulbocodium, the flowers being richly coloured; Veltheimia viridifolia; Melanthium junceum, Hepatica triloba alba, Primula verticillata, Sisyrinchium grandiflorum, with Aubrietias, Hepaticas, Anemones, &c. In the centre of the exhibit were plants of coloured varieties of Nicotianas. (Bronze Flora Medal.)

Messrs. HEATH & SON, Cheltenham, showed rock-garden plants and a collection of scented-leaved Pelargoniums. Amongst the Alpine plants were Corydalis Wilsoniæ, a fine pan of Primula frondosa, and Physochlaina orientalis.

The Misses HOPKINS, "Mere" Gardens, Shepperton-on-Thames, displayed a collection of coloured Primroses and other Alpine plants in a setting of stone and virgin-cork. (Bronze Banksian Medal.)

Mr. H. C. PULHAM, Elsenham, Essex, showed pots and pans of Alpine plants, with small Conifers and dwarf shrubs.

Mr. ROBERT SYDENHAM, Tenby Street, Birmingham, showed Lily-of-the-Valley and bulbous plants grown in moss-fibre in receptacles without provision for drainage.

Messrs. G. & A. CLARK, LTD., The Nurseries, Dover, showed Primroses, Lachenalias, Hepa-

ticas, Irises, Anemones and other spring flowers.

A small exhibit of Alpine plants was staged by the Misses E. & M. Kipping, Hutton, Essex.

Messrs. R. & G. Cuthbert, Southgate Nurseries, Southgate, Middlesex, filled a very long table with Hyacinths in pots. (Silver Banksian Medal.)

AWARDS.

Awards of Merit.

Iris Sind-pur Amethyst.—This charming variety is the result of the inter-crossing of I. sindjarensis and I. persica purpurea, the seedling partaking largely of the habit and freedom of flowering of the first-named parent, I. sindjarensis. The pervading tone of colour is violet, in deep and light shades, the style branches and the lower portions of the blades of the fall being of the deeper colour tone. The whitened character of the upper portion of the blade renders this part of the flower the more conspicuous. From C. G. Van Tubergen, Haarlem, Holland.

Shortia uniflora.—This Japanese species, as shown by Messrs. Wallace & Co., was awarded an Award of Merit. The flowers are rose-coloured, and vary in shade; they are 1½ inch in diameter. The illustration at fig. 97 shows

Fig. 98.—Shortia uniflora, flowering in a rockery at Colchester.
(From a photograph sent us by Mr. Kelley.)

a plant cultivated in Mr. Hinchmarch's garden at Alnwick, and at fig. 98 we have reproduced a photograph kindly sent us by Mr. Kelley, which depicts a colony of the plant growing in his rockery at Ivydene, Colchester.

Rhododendron Purity.—A magnificent greenhouse Rhododendron, of the same type as the variety Countess of Haddington, figured in our last issue, was shown by Mr. C. Turner, Royal Nurseries, Slough. The flowers were of very large size, unusual substance, very fragrant, and (excepting the merest suspicion of lemon-yellow on the upper segment) pure white. In form they were most regular. The parentage was not recorded.

Viola gracilis. — This very free-flowering purple Viola was shown by Messrs. Wallace & Co. It is an Oriental species, has oblong leaves narrowed at the base, later ones being linear-lanceolate; the flowers are of large size

Narcissus Committee.

Present: H. B. May, Esq. (chairman), and Messrs. J. T. Bennett Poe, P. R. Barr, J. D. Pearson, J. Pope, G. H. Englehart, Alex. M. Wilson, F. H. Chapman, A. Kingsmill, R. W. Wallace, E. M. Crosfield, A. R. Goodwin, H. A. Denison, W. W. Fowler, Chas. T. Digby, Joseph Jacob, W. Goldring, E. Willmott, P. D. Williams, E. A. Bowles, R. Sydenham, Jas. Walker, Walter T. Ware, G. W. Leak, Chas. Dawson, and Chas. H. Curtis (hon. secretary).

Messrs. Barr & Sons, King Street, Covent Garden, London, contributed a varied group of Daffodils representative of most of the sections of this flower. The best varieties were Lucifer, Sensation, Peter Barr (very fine), Monarch, Royal Star, Weardale Perfection, M. J. Berkeley, Grandis, Queen of Spain, &c. A large number of Darwin Tulips in excellent condition was staged by the same firm.

Mr. Chas. Dawson, Rosemorran, Gulval, Penzance, displayed a choice assortment of the newer kinds of Narcissus, including Estelle, a flower of the Sir Watkin type, with a fine orange scarlet rim to the crown. Other good varieties were Petticoat, a flower of the Ajax type, with frilled, expanded crown of lemon colour: Homespun, of uniform lemon shade, a shapely and refined bloom; Nora, sulphur and white; Chough, a variety with flattish, orange scarlet-coloured corona, and a nearly white perianth; and Althæa, with a pure white perianth and finely-crimped crown.

Messrs. Cartwright & Goodwin, Blakebrook, Kidderminster, staged a group of Daffodils, in which we noticed many novelties, the flowers being displayed with judgment and skill. Notable sorts were Mervyn (Emperor × obvallaris), with stiff, overlapping segments, a shapely and substantial flower; Evangeline; a lovely new Leedsii with a lemon-coloured cup; Glory of Noordwijck; Felicity, a charming flower of a uniform yellow shade, and said to be one of the earliest of Narcissus to bloom; also a fine bicolor seedling which promises to eclipse Glory or Noordwijck; Glitter, Mme. de Graaff, White Lady, and Citron. Many pots of finely-grown Daffodils contributed to the interest of this display. (Silver Banksian Medal.)

Mr. G. Reuthe, Keston, Kent, exhibited a few choice Daffodils in variety, chiefly of well-known varieties.

Messrs. R. H. Bath, The Floral Farm, Wisbech, contributed Tulips in many kinds, mostly early-flowering sorts, including Prince de Ligne, Parisian (white), Sarah Bernhardt (yellow), Prince, with variegated foliage, &c. Chionodoxas shown by this firm were of exceptional merit.

Miss F. W. Currey, Lismore, Ireland, displayed a representative exhibit of Narcissus, in which were seen such well-known kinds as Golden Spur, Mrs. Walter Ware, Santa Maria, Maximus, the handsome King Alfred, Cabeceiras (a flower with a finely-coloured trumpet), Mme. de Graaff, N. tridymus, &c.

Orchid Committee.

Present: J. Gurney Fowler, Esq., in the chair; and Messrs. Jas. O'Brien (hon. sec.), Harry J. Veitch, de B. Crawshay, R. Brooman-White, W. Bolton, C. J. Lucas, Stuart Low, F. Sander, G. F. Moore, H. G. Alexander, A. A. McBean, W. P. Bound, A. Dye, W. Cobb, J. Charlesworth, F. J. Thorne, H. A. Tracy, W. H. White, H. Ballantine, Gurney Wilson, F. J. Hanbury, and N. C. Cookson.

H. S. Goodson, Esq., Fairlawn, West Hill, Putney (gr. Mr. G. E. Day), was awarded a Silver Banksian Medal for an effective group, in which were about a dozen plants of the white-flowered Cattleya intermedia nivea; some good varieties of Odontoglossum crispum, and several hybrids; a showy variety of Cypripedium Countess of Carnarvon, with claret-coloured dorsal sepal having the upper third white, and other Cypripediums, &c.

Mr. A. W. Jensen, Lindfield, Sussex, secured a Silver Banksian Medal for a selection of fine forms of Cattleya Schroderæ similar to those shown by him at the last meeting, and including the variety alba. With them were a very handsome new form of Odontoglossum crispum of the punctatissimum class, with rose flowers margined white, the petals bearing clusters of small spots, and the sepals some large ones. Also two other spotted Odontoglossums.

F. Mentieth Ogilvie, Esq., The Shrubbery, Oxford (gr. Mr. Balmforth), showed Odontoglossum crispum Alexandrovitch, a finely-formed flower, showily blotched with purple; Dendrobium Wardianum, The Shrubbery variety, resembling album but with pink tips to the segments; the beautiful orange-coloured D. Thwaitesiæ, Veitch's variety, &c.

J. Gurney Fowler, Esq., Glebelands, South Woodford (gr. Mr. J. Davis), showed Odontoglossum Judith (sceptrum × loochristense), yellow-blotched with brown, and with the fringed lip of O. sceptrum; Cymbidium J. Gurney Fowler, with white flowers, having a purple mark on the lip; and Odontoglossum percultum "J. R. Roberts." (See Awards.)

De B. Crawshay, Esq., Rosefield, Sevenoaks (gr. Mr. Stables), sent Odontoglossum Astarte Harryanum × tripudians), resembling a very dark O. Harryanum, the sepals being almost entirely of a dark chocolate colour; and O. Andalusia (Andersonianum × loochristense), a very distinct pale yellow flower, prettily marked with purple-brown.

Messrs. Charlesworth & Co., Heaton, Bradford, staged a small group, in which were the fine purplish-rose Phalænopsis, Sanderiana Wigan's variety, which gained a First-Class Certificate in 1902; a finely-spotted form of Odontoglossum Fascinator, with a spike of 27 flowers, &c.

J. Wilson Potter, Esq., Elmwood, East Croydon, sent the handsomely-blotched Odontoglossum crispum Rossendale, and Empress of India.

Mons. Jules Hye de Crom, Ghent, showed the new seedling Odontoglossum Bingleyense, Jules Chenu (illustris × augustum), a finely-blotched variety, closely resembling Mr. Goodson's O. crispum Lily Bourdas.

W. James, Esq., Chichester (gr. Mr. W. H. Smith), showed two exceptionally fine forms of Cattleya Schroderæ.

J. Forster Alcock, Esq., Exhims, Northchurch, showed Cypripedium Bingleyense, Exhims variety, a very dark form with deep rose-purple dorsal sepal.

J. Braushaw, Esq., The Grange, Southgate (gr. Mr. Whitelegge), sent Cattleya Schroderæ "W. Duckham," a very fine pale lilac flower with purple-blotch on the lip; and C. s. The Kaiser, white with orange disc to the lip.

G. F. Taylor, Esq., Margery Hall, Reigate (gr. Mr. Seaman), sent Cymbidium Lowianum, Margery Hall variety, with pale yellow-green sepals and petals, and white lip with pale brown mark in front.

Messrs. WM. BALL & SONS, Chelsea, showed a small plant of a very finely-blotched seedling Odontoglossum crispum, flowered in three years from the sowing of the seed.

Messrs. HEATH & SON, Cheltenham, showed a selection of Cypripediums, including the fine C. Mrs. Wm. Mostyn; Dendrobiums, Epiphronitis Veitchii, &c.

F. W. MOORE, Esq., Royal Botanic Gardens, Glasnevin, Dublin, showed a very distinct form of Cypripedium Fairrieanum.

C. J. LUCAS, Esq., Warnham Court (gr. Mr. Duncan), sent Lælio-Cattleya Apollo with apricot-yellow flowers slightly tinged with rose.

NORMAN C. COOKSON, Esq., Oakwood, Wylam (gr. Mr. Chapman), sent Phaio-Calanthe delicata, having two spikes of cream-white flowers tinged with rose.

AWARDS.

FIRST-CLASS CERTIFICATE.

Cypripedium Helen II., Westonbirt variety (insigne Harefield Hall × bellatulum), from Major G. L. HOLFORD, C.I.E., C.V.O., Westonbirt (gr. Mr. H. G. Alexander). A grand Cypripedium displaying in a great degree the markings, fine size and other features of C. insigne Harefield Hall, with the wax-like substance and dwarf habit of C. bellatulum. The showy flowers are cream-white, the dorsal sepal bearing large rose-purple blotches, and the petals smaller spots of the same colour.

Phaius Clive (Norman × tuberculosus), from NORMAN C. COOKSON, Esq., Oakwood, Wylam (gr. Mr. H. J. Chapman). One of the finest of Mr. COOKSON'S many good hybrid Phaius, the habit being compact, flowers large, and of very rich colour. Sepals and petals rosy-lilac with a cream-white band up the middle; lip broad, mottled with claret on the basal half, the front being rose coloured with purple markings, the crest yellow and red.

Brasso-Cattleya Digbyano-Schroderæ superba, from Messrs. CHARLESWORTH & Co., Heaton, Bradford. A finely-formed white flower of good substance; the front of the lip is fringed and slightly tinged with pink.

Cattleya Suzanne Hye de Crom var. Jungfrau, from Mons. JULES HYE DE CROM, Ghent (gr. Mr. Coene). A larger variety of the white Cattleya for which a First-Class Certificate was given on March 17, and with a deep yellow throat on the lip.

AWARD OF MERIT.

Dendrobium Thwaitesiæ, Bound's variety (splendidissimum grandiflorum × Wiganiæ), from Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate (gr. Mr. W. P. Bound). A very distinct variety having yellowish buff flowers with purple disc to the lip, and measuring 4 inches across.

Odontoglossum percultum var. J. R. Roberts (Rolfeæ × ardentissimum), from J. GURNEY FOWLER, Esq., Glebelands, South Woodford (gr. Mr. J. Davis). A most charming and delicately-tinted hybrid. The broad and flatly-displayed sepals and petals are blush-pink, with a broad white margin, and with dense small purple spotting on the inner parts of the segments; lip large, white with rose-purple markings on the basal half. The plant bore a very fine spike of many large flowers.

Cattleya Schroderæ Queen Alexandra, from Messrs. SANDER & SONS, St. Albans. One of the largest and most distinctive forms yet shown, all the parts being very broad, and the colouring effective. Sepals and petals blush-white, the broad-fringed lip having a reddish-orange throat with a rose-purple band in front.

Cypripedium Berkleyana (Boxallii bellatulum), from J. FORSTER ALCOCK, Esq., Exhims, Northchurch, Berkhamsted. A pretty hybrid showing C. bellatulum strongly, the rich claret-purple markings nearly covering the cream-white ground. Mr. ALCOCK'S C. bellatulum, Exhims variety, the best-known form, was used as a parent, and the colour is much finer than others of the same cross.

CULTURAL COMMENDATION.

To Mr. H. G. Alexander (Orchid grower to Major G. L. HOLFORD, C.I.E., C.V.O.), for a grand specimen of Ada aurantiaca with 51 spikes of orange-scarlet flowers.

To Mr. H. TYSOE (gr. to Miss FITZPATRICK) for a large specimen of the fine old Cyrtopodium punctatum with five very stout, many-flowered spikes.

Fruit and Vegetable Committee.

Present: A. Dean, Esq. (chairman), and Messrs. W. Bates, J. Willard, H. Markham, H. Parr, E. Beckett, J. A. Davis, J. Lyne, W. Jeffries, P. D. Tuckett, T. Arnold, C. Foster, J. McIndoe, J. Harrison, G. Wythes, and C. P. A. Nix.

One of the principal exhibits before this committee was a collection of home-grown Oranges, sent by Messrs. T. RIVERS & SONS, Sawbridgeworth. At the back were trees in flower; dishes contained fruits of St. Michael, Egg, Large Round, Achilles, Dom Louise, and Navel Oranges. There were also large white Lemons, and a handsome fruit of Citron of Paradise. (Silver Knightian Medal.) Fruits of Dom Louise, Navel, and Achilles were presented for tasting. The first-named variety was scarcely ripe, and it was requested that it be sent again. The variety Navel was next considered. This Orange has a thin rind, and the flesh is soft and sweet. An Award of Merit was unanimously granted the variety.

C. RAPHAEL, Esq., Porter's Park, Shenley, Herts (gr. Mr. A. Grubb), showed 20 pot-plants of Royal Sovereign Strawberry, each plant carrying from four to six ripe fruits. Also five dishes of ripe fruits of the same variety. Many of the berries were of the flat or wedge-shaped type. (Silver Knightian Medal.)

Miss E. M. DIXON, Elmcroft Nursery, Chichester (gr. Miss Eve), showed a dish of Royal Sovereign Strawberry labelled "Improved," but no improvement was seen in the berries displayed.

Mr. T. LYNE, Chislehurst, exhibited Strawberry plants that had been placed in pots out-of-doors early in January, but not plunged. The roots were, in consequence, frozen hard, with the result that leaves and flower-stems were stunted and the latter "blind." It was the opinion of the Committee that Strawberry plants for forcing should be either plunged in the ground or be placed in frames during the winter.

HYACINTH COMPETITION.

The Royal Dutch Bulb Growers' Society at Haarlem offered prizes at this meeting for forced Hyacinths. The conditions required that each bulb must be grown in a separate pot, and must have been forced entirely in this country. The classes were divided into two divisions, one for amateurs and gentlemen's gardeners, the other for nurserymen. The response was poor; there were only 11 entries in the whole competition, including one from a nursery firm. The quality of the exhibits was of a low standard throughout; indeed, we failed to find a single truss that might be correctly described as distinctly good. This may be partly attributed to the bad quality of the bulbs this year, owing to last autumn being unfavourable for their ripening.

In the nurserymen's classes, as stated, only one firm competed. This was Messrs. R. & G. CUTHBERT, Southgate, London, N., and they showed in one class only, viz., that for 24 plants. The best varieties in the collection were Electra, Koh-i-Noor, Felix Faure, Garibaldi, Lady Derby, and Masterpiece.

In the amateurs' division, the class for 18 plants brought three exhibits, and of these two were placed equal as winners of the 1st prize. The exhibitors were Hon. VICARY GIBBS, Aldenham House, Elstree (gr. Mr. E. Beckett), and L. NOVLETT, Esq., High Street, Wavertree, Liverpool (gr. Mr. R. T. Bushell). Mr. GIBBS' best examples were City of Haarlem (cream-yellow), King of Blues, Cardinal Wiseman (pink, with darker centre), Lady Derby (pink), Electra, and Mary (dark blue). Mr. NOVLETT showed King of Blues, Roi des Belges (red), Electra, Marie, &c.

There were four contestants in a class for 12 Hyacinths, the 1st prize being won by Lord HOWARD DE WALDEN, Audley End, Saffron Walden (gr. Mr. James Vert); 2nd, Hon. WHITELAW REID, Wrest Park, Ampthill, Beds. (gr. Mr. G. Mackinlay).

The best exhibit in a class for six plants was shown by J. A. BEVAN, Esq., Trent Park, New Barnet (gr. Mr. H. Parr).

Scientific Committee.

MARCH 17.—*Present:* E. A. Bowles, Esq., M.A., F.L.S. (in the chair); Dr. M. C. Cooke, Messrs. C. E. Shea, R. H. Curtis, W. B. Hemsley, W. Hales, H. J. Elwes, J. T. Bennett-Poë, A. Worsley, L. de B. Crawshay, E. M. Holmes, W. C. Worsdell, G. S. Saunders, H. T. Güssow, and F. J. Chittenden (secretary).

Inosculation in Hornbeam.—Messrs. JAMES VEITCH & SONS sent branches of Hornbeam (Betulus carpinus), taken from a garden hedge, in which a very perfect junction had occurred between the two by a sort of natural inarching or inosculation, as it is more properly called. Mr. ELWES drew attention to the fact that if young Hornbeams are planted so as to form a lattice, as time goes on, inosculation occurs wherever two stems come in contact, and finally an impenetrable hedge is formed.

Tubers of Sechium edule.—Large tuberous roots of this plant, grown from a plant in a pot in the Melon house at Wisley, about the beginning of September, were shown by Mr. CHITTENDEN. The plant had produced several large tubers, and these are said to be very palatable when cooked, and greatly resemble Yams in appearance. The plant had been received under the name "Chrystophine," and is also called "Choco." The plants had not fruited at Wisley.

Crosses of Albino Orchids.—In reference to Mr. HURST'S communication to the last meeting upon this point, Mr. ROLFE wrote: "Paphiopedilum insigne Sanderæ × P. bellatulum album does not yield an albino hybrid (see *Orchid Review*, 1908, p. 72), as should have been the case according to the theory mentioned by Mr. HURST at the last meeting. It has very numerous minute purple dots on both the petals and dorsal sepal, though the ground colour is whiter, and the spots fewer and very much smaller than when the ordinary forms of the species are crossed. P. bellatulum album 'selfed' would, I have little doubt, come true, and P. insigne Sanderæ × P. Lawrenceanum Hyeanum I should expect to give coloured hybrids, because it is a precisely parallel cross to P. insigne Sanderæ × P. callosum Sanderæ, and combines the same quite distinct sections of the genus. P. callosum and P. Lawrenceanum (with, of course, their albino forms) are very intimately allied. The mysterious 'factor' supposed to be involved, I believe to be simply the opportunity for reversion which is afforded by crosses between such diverse species. The two combinations last mentioned should certainly be attempted."

Dwarf form of Rhododendron triflorum.—From E. I. P. MAGOR, Esq., of St. Tudy, Cornwall, came a specimen of the dwarf form of Rhododendron triflorum, raised at the Royal Gardens, Kew, from seed sent there by Mr. PETER BARR. The plant is not a foot high, and flowers in Cornwall in the open from a month to ten weeks earlier than the type, the earliest date being the last week in February, 1905.

Seeds germinating in fruit.—From Mr. CAVE, of The Gardens, Holker Hall, Cark-in-Cartmel, came a fruit of Tomato in which several of the seeds had germinated, some of the seedlings having thrust their way out through the wall of the fruit and become green. The phenomenon is not very uncommon, and examples may at times be found in Oranges, Lemons, Melons, and some other fruits, while in some plants, such as the Mangrove, it normally happens that the seed germinates while the fruit containing it is still hanging on the plant, and the same thing has been recorded as occurring in Sechium edule.

Dominance and reversion in Dendrobium crosses.—GURNEY WILSON, Esq., of Glenthorne, Haywards Heath, showed pseudo-bulbs of a cross-bred Dendrobium, and of its parents, D. nobile Ballianum ♀ × D. nobile Murrhinianum ♂. The pseudo-bulb of D. nobile Ballianum is straight, while that of the other parent is zig-zag in growth, owing to the presence of a very marked projection at the nodes on each side of the pseudo-bulb alternately. Of 150 seedlings of this cross all showed in a marked manner in their pseudo-bulbs the zig-zag character of the pseudo-bulb of D. nobile Murrhinianum. In both parents the flowers are white, but have a faint purplish spot in the centre of the throat. In all the 150 cross-bred plants the flower has

reverted to the typical coloration of the species, the spot in the centre of the throat being dark, and the other perianth pieces being marked with purple.

WINTER-FLOWERING CARNATION.

April 1.—This society held its spring show at the Royal Horticultural Society's Hall, Vincent Square, Westminster, on this date. The building was fairly well filled, for the reason that many exhibits remained from the meeting on the previous day of the Royal Horticultural Society.

The Carnation Society is to be congratulated upon the success attending its efforts to establish a spring show of Carnations, a matter difficult to realise before the advent of the American varieties. The opening class in the schedule was one for varieties new to commerce. The only one of merit was Burrswood Scarlet, a regular-formed flower, with smooth edged petals and of regular outline. The judges desired to see it again in the winter.

Colour Classes.

White.—In the class for 36 blooms of a white variety, the 1st prize was won by Mr. W. H. Lancashire, Guernsey, with exceptionally fine blooms of White Perfection. 2nd, Mr. W. E. Wallace, Eaton, Bray, with the variety Lady Bountiful, which has deeply serrated petals, by some persons considered an added attraction. 3rd, Mr. G. Lange, Hampton, Middlesex, with White Perfection.

For 18 white blooms the 1st prize was taken by Messrs. Bell & Sheldon, of Guernsey, with Lady Bountiful. 2nd, Mr. W. E. Wallace, with White Perfection, the flowers being extremely large and loose. 3rd, Messrs. Morres & Co., with White Perfection, having neater blooms than the foregoing.

Blush.—For 36 blooms of this colour, Mr. W. H. Page, Hampton, Middlesex, took the premier prize with Enchantress. 2nd, Mr. W. H. Lancashire, with the same variety. The exhibit of this variety by Messrs. Morres & Co., Guernsey, was very highly commended, but no other awards were made. There were five exhibits in this class.

For 18 blush-coloured blooms, Messrs. Bell & Sheldon were placed 1st with Enchantress, which were probably the best examples of the variety in the hall. 2nd, Messrs. B. & V. Haig, Maidenhead, with Enchantress. 3rd, Mr. C. Engelmann, with the smaller-flowered, light pink Lawson (Melody), a variety whose tint is slightly more intense than that of Enchantress.

Pink.—For 36 blooms of a light pink-coloured variety only two exhibitors contested, and only one award was made, that of a 2nd prize to Mr. C. Engelmann, of Saffron Walden, for Fiancee, a much-fringed, rose-pink coloured variety.

For 36 blooms of a deep pink variety the 1st prize was won by Mr. W. H. Lancashire, Guernsey, for fresh blooms of Mrs. T. W. Lawson. 2nd, Mr. W. H. Page, Hampton, with the same variety.

For 18 blooms of a light pink variety.—1st, Mr. A. F. Dutton, Iver, Bucks., with Winsor, full, and very pleasing in tint and shape. 2nd, Messrs. Bell & Sheldon, with Winsor. 3rd, Mr. C. Engelmann, with Mrs. H. Burnett.

For 18 flowers of a deep pink-coloured variety.—1st, Mr. W. E. Wallace, with Nelson Fisher, a fine richly-coloured flower, lacking strength in the stem, so that unless supported the bloom turns its face downwards. 2nd, Messrs. Bell & Sheldon, with Mrs. Lawson. 3rd, Mr. S. Mortimer, with the same variety.

Crimson.—For 36 blooms of a crimson variety Mr. W. H. Lancashire was 1st with Harlowarden. 2nd, Mr. C. Engelmann, with the same variety.

In the class for 18 blooms of a crimson variety the 1st prize was awarded to Messrs. Bell & Sheldon, who showed the variety President, all the flowers being perfect, with stems supporting the blooms erect. 2nd, Messrs. Morres & Co., with Harry Fenn, the colour of which is more refulgent than that of Harlowarden. 3rd, Messrs. B. & V. Haig, with Harlowarden.

Scarlet.—In the class for 36 blooms of a scarlet variety, the 1st and a Special Prize in the vase class were taken by Mr. W. H. Lancashire with the variety Robert Craig. 2nd, Mr. C. Engelmann.

For 18 blooms of a scarlet variety Mr. A. F. Dutton was placed 1st with Beacon. 2nd, Messrs. Morres & Co. with Robert Craig. 3rd, Mr. E. H. Sams, Worthing, with blooms of Robert Craig.

Fancy varieties.—For 36 blooms of a fancy Carnation, Mr. C. Engelmann was awarded the 1st prize, with Jessica, a white, flamed scarlet.

In the smaller class for 18 blooms of a fancy variety, the 1st prize was won by Mr. C. Engelmann with Imperial, a flower with a pink ground, having scarlet flaking and a dentate edging to the petals.

Mr. W. H. Lancashire was awarded the 1st prize for 18 blooms of a variety not in commerce: Ivanhoe, a flower of deep rose tint, full, and, as shown, not of a large size.

For blooms of the variety Mrs. H. Burnett, a single variety class, Mr. W. H. Lancashire won the 1st prize with 25 blooms, the perfection of form and condition.

For 25 blooms of Britannia, the 1st prize fell to Mr. E. Wallace.

Mr. W. H. Lancashire was awarded a 1st prize for a vase of the variety Mrs. H. Burnett.

Mr. A. F. Paskett, Gloucbridge, secured a 1st prize for a basket of Carnations.

Bouquets were few. A 1st prize was taken by Mr. Hayward, of Kingston-on-Thames.

Honorary Exhibits.

Mr. H. Burnett, Guernsey, received the society's Award of Merit for Carnation Mikado, a sombre-coloured variety having cupped, inward-turning petals, and fairly double; also a First-Class Certificate for Marmion as a new break, it being a scarlet-flaked flower, with broad edges of white to the petals. Mr. Burnett was also the recipient of a Gold Medal.

Gold Medals were awarded to Mr. W. H. Page, Hampton; Mr. C. F. Waters, Balcombe, Sussex; and Messrs. Hugh Low and Co., Enfield, for displays of Carnations.

Silver-Gilt Medals were awarded to Messrs. Morres and Co., Guernsey; Mr. A. F. Dutton, Iver, Bucks; and Messrs. Bell and Sheldon.

Silver Medals were gained by Mr. C. Engelmann, Saffron Walden; and Mr. G. Lange, Hampton.

LINNEAN SOCIETY.

March 19.—At a meeting held on this date, the following exhibitions were shown by permission of the Director, Royal Botanic Gardens, Kew:—

(1) Mr. W. Botting Hemsley, F.R.S., F.L.S., sent for exhibition a second specimen of Platanthera chlorantha with three spurs, which was described in his absence by Mr. C. H. Wright, A.L.S. The plant now shown came from the Rev. E. A. Woodruffe-Peacock, F.L.S., to whom it had been sent by Miss Susan Allett, of Bath, and exhibited a spike, each flower of which had the three petals spurred, a case of true peloria, whereas the specimen shown on January 17, 1907, had the three sepals spurred, a case of false peloria.

In consequence of the publication of the latter specimen in the Society's *Journal* (Botany, Vol. xxxviii. (1907) p. 3), Cav. Sommier has drawn attention to the occurrence of true and false peloria in P. bifolia in the neighbourhood of Florence.

(2) Mr. T. A. Sprague, F.L.S., showed female flowers and fruits of Sterculia Alexandri, Harv., an extremely rare tree from Uitenhage, the only locality known for it, where it was first found in January, 1848, by Dr. R. C. Alexander, F.L.S. (afterwards Prior). The specimens shown had been collected by Dr. S. Schonland, F.L.S., who reported that the seeds were of pleasant taste resembling a chestnut, and were greedily sought after and devoured by the baboons.

(3) Mr. C. H. Wright, A.L.S., showed specimens of (a) Sphærothylax algiformis, Bisch., a rare South African Podostemaceous plant, and spoke of the outward resemblances of some plants of this family to certain cryptograms, showing side by side examples of Hydrostachys imbricata, A. Juss., and H. nana, Engl., as resembling the alga Caulerpa cupressoides, and Fristicha hypnoides, Spreng., with the form of a moss; also (b) Archangiopteris Henryi, Christ and Gilsenh., a Chinese genus of Marattiaceæ, of which a better supply of material had been recently obtained.

A paper, by Mr. T. F. Chipp, was communicated by Mr. W. Botting Hemsley, F.R.S., F.L.S., and entitled "A Revision of the genus Codonopsis," was introduced by the author, who explained that the recent accession of new material through Mr. A. Henry and Mr. E. H. Wilson had necessitated this revision. He included the genus Glosocomia of D. Don, and other species which could not well be assigned to either. The genus was divided into four sections dependent upon the attachment and insertion of the corolla and calyx. Finally the distribution of this genus along the mountain ranges of Asia was described and illustrated by a map on the screen.

Obituary.

Wilhelm Kelhofer.—The death is announced of W. Kelhofer, professor in the horticultural school, and head of the chemistry section of the experiment station for fruit, wine, and horticulture in general at Wädenswill, Switzerland, which occurred on March 7, at the age of 46 years. The deceased was a hard worker, and he had accumulated much valuable knowledge; to him it was due that the Wadenswill institution, more particularly in agricultural circles, was held in high estimation in Switzerland. His researches in the clarification of fruit wines—a matter of great importance in southern Germany and Switzerland, which had previously been undertaken with but little satisfactory results—met with great success, and proved of great advantage to the Swiss fruit cultivators and others. It was Kelhofer who insisted on the use of sugar in the preparation of the Bordeaux Mixture, in order to keep it effective for long periods of time. He published accounts of his experiments with various substances for the destruction of fungous and animal parasites of field and garden plants in the horticultural and agricultural Press; and his *Leitfaden* (guide) for chemistry in the agricultural schools, with special reference to fruit, wine, and nurseries, is a very useful book.

Thomas Pike Turner.—The death of this nurseryman occurred on March 19, at Hammersmith, in the 65th year of his age, after a long and painful illness. The late Mr. Turner carried on business for some years as a nurseryman at King Street, and latterly at Bridge Road, Hammersmith. He was born at Andover, Hants, where his father was engaged in horticultural pursuits, and was apprenticed to Mr. Charles Turner, of Slough. He served as under gardener at Bowood Park, Calne, and in the late Lady Waldegrave's gardens at Strawberry Hill, Twickenham. Subsequently he went to Wakefield (Yorkshire), and afterwards came to London as gardener to the late Mr. T. V. Morgan, of Beaufort Lodge, Chelsea. Mr. Turner also served as gardener to the late Earl and Countess of Meath, Kilruddery Castle, near Bray, Ireland, which position he held for five years. He filled for the next five years the office of gardener to Col. and Mrs. Alcock Stawell, of Kilbrittain Castle, Co Cork. On his return to this country he was with the late Mr. J. Lamis, of Merton, for some time. The late Mr. Turner will be chiefly remembered as a successful florist at Hampshire House Nursery, Hammersmith, now the Hampshire House Club. In his younger days deceased was a contributor to our columns. The funeral took place at the Hammersmith Cemetery on Monday, March 23.

CATALOGUES RECEIVED.

Clibran's, Altrincham, Manchester, and Bramhall—Indoor plants.

E. Justus, 48A, Charing Cross Road, London, W.C.—Books on Natural History (second-hand).

DEBATING SOCIETY.

SALISBURY AND DISTRICT GARDENERS'.

At a recent meeting of this society, held under the presidency of Mr. T. Challis, a lecture on "Cyclamen" was given by Mr. Goatly, of the Guildford Gardeners' Association, and a delegate from the Royal Horticultural Society, W. Y.

THE WEATHER.

THE WEATHER IN WEST HERTS.

Week ending April 1.

A continuous fall of rain for 36 hours.—This was a week of about average temperature. During the last six days the highest temperatures in the thermometer screen ranged only between 49° and 52°, and on the coldest night the exposed thermometer showed only 4° of frost. The ground is now at about a seasonable warmth, both at 1 and 2 feet deep. Rain fell on four days, to the total depth of 1¼ inch. The continuous rainfall mentioned in the last report came to an end at 9 a.m. on the 26th, having lasted without intermission for 36 hours—the aggregate measurement, however, amounted to scarcely an inch. There occurred a sharp thunder shower of rain and hail, accompanied by high wind, shortly before 2 a.m. on March 31st. During the week five gallons of rain water came through the bare soil percolation gauge, and four gallons through that in ground on which short grass is growing. The sun shone on an average for 4¼ hours a day, or for a quarter-of-an-hour a day longer than is usual at the end of March. The last three days of March were very windy, and in the windiest hour the mean velocity amounted to 21 miles—direction west. The average amount of moisture in the air at three o'clock in the afternoon fell short of a seasonable quantity for that hour by 2 per cent.

MARCH.

Very cold and wet, with an average record of sunshine.—This was the coldest March for seven years. In the middle of the month there occurred a very cold period lasting 10 days, during which there was not a single unseasonably warm day or night, and on the coldest night, which was also the coldest of the month, the exposed thermometer registered 16° of frost, which is about the average extreme minimum for March. On the warmest day the temperature in the thermometer screen rose to 57°, which is an exceptionally low extreme maximum for the time of year. Rain, hail, or snow fell on 19 days, to the aggregate depth of 3¾ inches, or 1½ inch above the March average. Snow fell on six days, and on the 2nd and 3rd the ground was covered to the mean depth of 1½ inches. The sun shone on an average for 3½ hours a day, which is about an average record for March. This was on the whole rather a calm month, owing principally to 10 very calm days in the middle of it. In the windiest hour the mean velocity rose to 21 miles—direction W. For only 153 hours, or about six days, was the direction of the wind any point between N. and E. The mean amount of moisture in the air at 3 p.m. exceeded a seasonable quantity for that hour by 3 per cent. *E. M., Berkhamsted, April 1, 1908.*

ENQUIRIES AND REPLIES.

ARTIFICIAL MANURES.—In reply to the enquiry of *W. C.* on page 206, it may be stated that probably more artificial manure is used at the Rothamsted Experimental Station than at any other place in the country, and has been so employed for the past 60 years. The experience gained at Rothamsted shows that very much depends on the character of the soil, the crop grown, and upon the season, as to whether nitrate of soda and sulphate of ammonia should be dug or ploughed in, or sown as top-dressings only. Nitrate of soda, which is much more easily washed into the sub-soil and out of root-range than sulphate of ammonia, should certainly be top-dressed only on the lighter descriptions of soil, and dug or ploughed in very shallow on the heavy clay soils; the depth should not exceed 3 or 4 inches. As an example of the ease with which nitrate of soda is washed away, it may be mentioned that a few years ago a field of winter Oats at Rothamsted was being top-dressed with nitrate of soda. The sowing drill had gone once across the field when an exceedingly heavy thunderstorm came on and the work had to be stopped for some days, when the remainder of the field was sown. Throughout the whole season the one strip sown before the storm could be distinguished, and at harvest the crop was but little better than that obtained from unmanured land, while the portion which received the nitrate of soda after the heavy rain had fallen, yielded an excellent crop. Sulphate of ammonia, on the other hand, is not so readily soluble nor so liable to be washed away by heavy rains. But even this manure should not be ploughed or dug in deeper than 4 inches, and for most crops it is better applied as a top-dressing. *J. J. Willis, Hampshire.*

VALUE OF MOTOR LAWN MOWERS.—I should be grateful if readers would state their recent experience with motor lawn mowers. So far as I know the latest statements contained in the *Gardeners' Chronicle*, June 23, 1906, p. 415 were not favourable, and the remarks in the issue for July 7, 1906, p. 20, refer to new experience, and are not altogether in favour of the motor. Many of the lawns here have a somewhat steep slope. *H. H. Maiden, Director of the Botanic Gardens, Sydney.*—[An illustrated article was published on this subject in our issue for March 7 last, but the experience of actual users of these machines would be valuable.—ED.]

ANSWERS TO CORRESPONDENTS.

BAMBOO: *S. A. T.* The Bamboo you send in flower is Phyllostachys nigra var. punctata. We do not think there is any hope of your saving the plant. We have seen scores that have flowered, but not one of them has survived. It is said that there is hope of saving a plant if it is cut down to the ground immediately any evidence of flowering appears, but we very much doubt if this would be effective.

BROCCOLI: *W. H. N.* There is no insect or fungus present in the specimens received.

CATTLEYAS WITH YELLOW LEAVES, &c.: *W. H.* All damaged or very old pseudo-bulbs should be cut off close to the rhizome and any damaged leaves removed. If you keep the atmospheric heat at 60° Fahr. at night it will be high enough. In any case, provide that the temperature shall be 7° or 8° at least below the temperature which obtains during the day-time.

CROCUS: *J. K. M.* The Tulips and Crocuses are attacked by Sclerotinia parasitica. The Hyacinth bulb is badly infested with Bacterium hyacinthi. Both these pests remain in the soil from year to year, and attack fresh plants of the same kind. The soil should be treated with quicklime. The other plants mentioned might be planted in the gaps, as they are not liable to be attacked by either of the parasites.

FUNGUS: *H. D. W. W.* Tremella albida.

INSECTS: *J. B. C.* The larger of the two kinds of grubs are those of a fly belonging to the genus Bibio, they are very probably those of the St. Mark's fly, which is very common; it derives its name from the fact that the perfect flies usually appear about St. Mark's day, (April 25). The se flies and other species belonging to the same genus may often then be found flying about in large numbers; they do not fly well but go from one shrub or plant to another, often in couples; they are black, with comparatively slender bodies, and are about ⅜ths of an inch in length; the grubs probably feed on the roots of plants. The smaller white grubs are also the grubs of a fly. Both may be killed by working "vaporite" into the soil round the plants that they are attacking; liquid insecticides are of little or no use, as they lose their strength on passing through the soil.

LILIUM: *Nemo.* There is no trace of fungus disease or insect pest. We cannot form an opinion upon the cause of the flower buds failing to develop.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. *Correspondents not answered in one issue are requested to be so good as to consult the following numbers.*

FRUITS: *W. G.* Baxter's Pearmain.—*J. H.* 1, Lady Henniker; 2, Smart's Prince Arthur; 3, Gascoyne's Scarlet Seedling.

PLANTS: *A. J. B.* 1 and 2, Helleborus orientalis; 3, H. o. variety rosea.—*W. A. C.* Cupressus obtusa var. filicoides (Retinospora filicoides).—*D. M. K.* Dendrobium moschatum.—*W. E. H.* Dendrobium fimbriatum.—*A. R.* 1, Odontoglossum pulchellum; 2, Oncidium platextum; 3, Stelis ophioglossoides; 4, Aida aurantiaca.—*W. H.* Begonia fagifolia.—*T. W.* 1, Odontoglossum cordatum; 2, Odontoglossum luteo-purpureum; 3, Epidendrum elongatum; 4, Odontoglossum cirrhosum; 5, Laelia Cowanii (yellow forms); 6, Oncidium luridum.—*Nobile Orchid.* Dendrobium nobile Cooksonianum.—*H. J. P.* 1, Iris japonica, often called Iris fimbriata in gardens; 2, Chorizema cordatum; 3, Strelitzia Reginae.—*C. J. Ellis.* Your plant is known in gardens as Farfugium grande, but the correct name is Senecio Kaempferi.

NECTARINES FAILING TO SWELL: *Correspondent.* If you cut open the smaller fruits, you will find that the embryos are shrivelled and brown, which shows that they have not been properly fertilised. If the fruits are not fertile, they are certain to drop at what is known as the "stoning" period.

PUBLIC PARKS: *Calanthe.* Read the articles on p. 23 and 39 of the *Gardeners' Chronicle* for January 11, 18. It will be necessary for you to gain practical experience in park work by obtaining employment yourself in one of the parks.

RATS: *W. G.* Have you tried "Ratin," a virus sold for killing these rodents?

RHODODENDRON BUDS EATEN: *Constant Reader.* The buds have the appearance of being damaged by some animal or bird, probably by pheasants.

TOMATO LEAVES DISEASED: *C. B.* The plants are badly attacked with the disease known as Cladosporium fulvum. Burn the diseased plants and spray those not affected with the Bordeaux mixture. Do not grow Tomatos in the same house again until the structure has been thoroughly cleansed, using a weak solution of carbolic acid for the woodwork, &c. You have afforded the plants too much moisture and not sufficient ventilation.

TUBEROUS BEGONIAS: *A. P., Stockport.* Many of the older varieties may be readily propagated from cuttings, but the more modern sorts having thick, fleshy stems are difficult to increase in this manner. At the same time if there are any side shoots or more than one growth from the base, even if the cuttings are thick and fleshy, they may be induced to make roots. They must be cut off quite close below a leaf, and in the case of short cuttings the basal leaf may be left on, but if removed it should be taken off quite close to the stem, care being taken not to damage the bud in the axil. Insert the cuttings in light sandy soil and place them in a close frame with bottom heat, but do not apply much moisture. It would be doubtful if plants suitable for bedding out the same season could be grown from cuttings, except those of the older type, which are more nearly allied to B. boliviensis. There are several of these, and also others of a smaller habit of growth which make numerous thin shoots which root freely and soon form useful plants. The safest method to insure a good stock of Begonias for bedding is to sow seed in the previous year. The young plants may be grown in a comparatively small space; the colours can then be sorted out and useful tubers secured, which should be dried off in the autumn, cleaned, and kept in a dry place where the heat will not fail below 40° Fahr. If such tubers are started into growth in March, or even April, they will develop rapidly. Your seedlings ought to have made a good start by this time. Probably the roots are not in a suitable medium, and you would save time if you pricked them off again, taking care to provide good drainage and a compost consisting of good loam, leaf-mould, and sand. Place them in a warm house or frame where the sun will not shine fully upon them. If it is necessary to provide shade, see that it is removed each day as soon as the bright rays of the sun will no longer reach the plants. Begonias do not need a great amount of heat, but they require careful and regular attention, good soil, and plenty of sunlight without being fully exposed to its rays.

WAGES DURING ILLNESS: *C. B.* If the circumstances are as you appear to describe them, your employer should have paid the wages until the expiration of the fortnight's notice.

FLOWER GARDENING.

THOUGH a hardier class of plants is being generally employed in the embellishment of the flower garden than was usual not so many years ago, flower gardening has not by any means been simplified, but has rather been rendered more difficult. Quite as strong colours are used as formerly, but in conjunction with them and to a still greater extent, soft shades are being more and more called for, which cause not a little trouble to group satisfactorily. The effect of using plants of vigorous growth having colours of a wider range is often good, though seldom free from imperfections, resulting from placing colours which clash with each other in juxtaposition. Some of the compositions' one sees are as crude in colouring as anything that prevailed in the old "bedding" days; at the same time there is now greater individuality, and though there is still copying enough, there is nothing like the stereotyped arrangements at one time common in almost all gardens.

The flower gardener of the present day is happy in being able to select material from a wider and more varied range of plants than his predecessor, nothing coming amiss that can be effectively employed. There is, however, a danger of departing from that pleasing simplicity which is generally admired, and of adopting meretricious graces which repel. Probably white is more capricious than any colour, and by trusting unguardedly to the neutrality of its tone a bad result may follow its use instead of that enhanced effect for which white is so useful. The yellow-white of Snapdragon (Antirrhinum) gives a totally different effect from the green-white of varieties of Larkspur. Brown, not commonly admitted to the garden, is warmed by the former, and robbed of all its charm by the latter. I remarked last year a very pleasing grouping of grey and yellow-whites, the charm of which was dissipated by the intrusion of a few plants of Gladiolus brenchleyensis. Nor do I admire the frequent composition of the latter with Galtonia candicans, bordering, as it does, on the crude. Blue flowers are in general difficult to deal with. Nothing in blue can surely surpass the beauty of Salvia patens, yet how seldom is it suitably matched! A Fuchsia of Madame Cornelisson type goes well with it. Some contrast it with yellow, which, if of lemon or citron strength only, is passably good, but even that may be spoiled by adding white. The pinky-apricot of Golden Chamois Snapdragon is preferable to yellow, and, possibly, nothing matches better with it than the grey of the Phalaris arundinacea variegata, of Cerastium tomentosum, or of Cineraria ragusina. Pentstemon heterophyllum affords another example of a plant the colouring of which is difficult to match. It is lovely when properly treated, and I think that nothing suits it quite so well as dotting the plants on a groundwork of the yellow-leaved Mesembryanthemum cordifolium. I tried it last year in conjunction with Celsia arcturus, a gracious plant for the flower garden, but the grey-green of its leaves detracted considerably from its effectiveness. Lobelia tenuoir gives a brilliant effect along with Monsoa Warscewiczii, both used in blocks of colour, and A. Mutisii may also be recommended for its unique colouring.

Of Calceolaria, the only species I now grow is C. amplexicaulis, the yellow of which no one can truthfully aver to have the slightest touch of commonness, and it is remarkable what a variety of plants can be effectively arranged with it. I mention only crimson Pentstemons; Verbena Miss Willmott (deep orange); Nemesia; salmon, rose, and deep blue Larkspurs; almost all the tall Snapdragons; Rose Queen Hollyhocks; Orange King Marigold, and Xeranthemum annuum.

Geum chilense, along with Goacher's Crimson Chrysanthemum, was much liked last year, though, personally, I do not care much for the former plant. Rhodanthe Manglesii and R. maculata alba are particularly dainty subjects, which seem to have been hitherto overlooked. Both have a good effect if dotted among the new double Lobelia. They may be raised apart from the flower garden, but they will also succeed if sown in the position where they are to bloom. Perhaps of all flowers, tall Snapdragons are the most dependable and capable of affording the greatest pleasure. Provided the colours are aptly chosen, they are splendid when planted in large groups. At the same time, there are colours among them that should not be admitted to the flower garden. I had a very pleasing bed last year composed of irregular groups, that in the central part was tall crimson, and was surrounded by tall rose, tall carmine pink, Golden Chamois, and tall yellow-flushed crimson. The portions not occupied by these were filled with Rosy Morn, intermediate Carmine Pink and intermediate Orange King. Yellow and white were deliberately excluded. Snapdragons possess much adaptability and group well with a great variety of plants. A lovely combination is produced with Rose Queen Hollyhock, then dark blue Larkspur, then Snapdragon Golden Chamois, then Nigella Miss Jekyll, and Celsia arcturus, all in considerable quantities, but by increasing or diminishing any one of these the effect is altered.

A rather pleasing grouping consisted of tall crimson and white-throated Antirrhinum, many of the inflorescences shooting up to 6 feet in height, among which were single-stemmed plants of an early grey-flowered Aster, which was topped during summer. Larkspurs of all kinds are invaluable for summer and autumn. The earliest to flower are those of the Rocket section, and it is worth while to sow seeds of this a month later than seeds of the other annual sorts. There are lovely shades of light blue, pink, and rose which are well worth keeping separate. These were very pretty in a border of Stocks, along with Tropæolum peregrinum. Emperor Larkspurs are to be had in a few desirable colours, and should be arranged in fairly large masses. A good result is obtained with azure-blue sorts dotted here and there with a rose, and here and there with a white variety. These produce an effect altogether distinct from that of any other flower. Stock-flowered Larkspurs are a taller selection and equally valuable. Last season, early-raised seedlings of perennial light blue Delphiniums, with the lower leaves removed and set among Lobelias, gave a pretty, but too short-lived effect. Perhaps the best of the perennial section is Queen of the Blues, which has to be raised quite early in the year, and planted about 6 inches apart. The common blue branching Larkspur mixes nicely with this, and if a Begonia of the right shade of red is selected, a glorious and glowing combination results. But if the shade is wrong ——! A series of borders furnished jumble fashion, with a variety of plants ranging from white to brown-red, were much liked by some people. The dwarfest plant employed in the scheme was dwarf Pearl Nasturtium. Liberal masses of mixed Montbretias came up here and there to the edge of the grass, the rest of the space being occupied with Scotch, French, and African Marigolds, which provided rich browns, oranges, and light yellows. Tall yellow Snapdragons gave another tone, and a brighter yellow was secured by the free use of a Chrysanthemum. The Ribbon Grass, Phalaris arundinacea variegata, provided a neutral tint, and a few Galtonias were added, as much for the sake of distinction of form as anything else. There was a backing of grey-green to the whole and grass-green in front, both of which probably were needed to neutralise the strong colouring, which, as planted, was not too garish.

A simple but formal bed which appealed to ladies, whose taste, as far as my experience goes, often does not run in the same

direction as that of their gardeners, was planted with crimson Begonias intermixed with an equal number of Chlorophytum elatum—the yellow-leaved form—and the ground thickly carpeted with the variegated Ice-plant. The Begonia arrangement that appealed most strongly to gardeners was a long border of all colours, yellow and white being excluded, with a carpeting of Königa variegata, which was clipped at regular intervals. The quantity of manure dug into the soil, in addition to that applied as surface dressings and dissolved in water which these Begonias assimilated, almost surpassed all belief. Yet they throve amazingly. There are dozens of plants which space will not permit even to name for which there is room in most gardens. Verbena venosa, Gazania splendens, Harrison's Musk, Cuphea strigilosa, Lobel's Catchfly: how seldom are they seen!

It was painful last year to see in many gardens incomplete arrangements through failure of growth. This is a drawback incidental to the employment of so great a variety of plants, and although it may be expected to occur annually, it was accentuated by the unfavourable weather of 1907. To meet these losses reserve plants, not necessarily of the same species, should be grown to fill up such gaps. These are also useful to take the place of any plant offensive in its colouring, which it is far better to remove than to allow it to remain as an eyesore for weeks and months. Not a season passes but I find it necessary to alter in this way arrangements which at planting it was hoped would be perfect, but which failed on flowering to give the satisfaction expected. *B.*

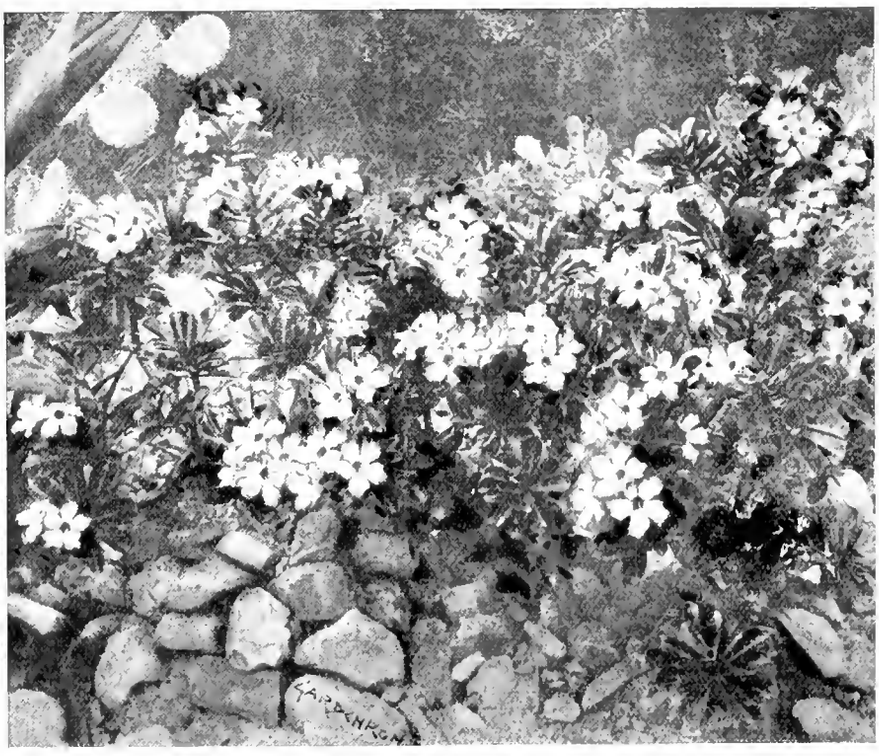

FIG. 99.—ADENIUM OBESUM GROWING ON A ROCKERY AT HOPE GARDENS, JAMAICA: FLOWERS PINKISH-CRIMSON.

ADENIUM OBESUM IN JAMAICA.

A SMALL plant of Adenium obesum (Roem. and Schult), belonging to the order Apocynaceae, was received from Kew Gardens in August, 1898, and planted at Hope Gardens, Jamaica. It was planted out on a low rockery which had been built for Agaves, Cacti, &c. It proved such an attractive plant that attempts were made to propagate it by means of cuttings, but these all failed. Then enlayering was tried, and to effect this, the rockery was built up with loose stones round some of the branches, and a little soil was filled in. The branches rooted readily, and in this way about a dozen large plants were raised. Some of the rooted branches were not removed, and we have now a multiple plant, 5 feet in diameter, and 14 feet 6 inches in circumference. When photographed by Mr. W. J. Down last November, it had 114 expanded blooms, the individual flowers varying from 2½ inches to 3 inches in diameter. Last September it produced seeds for the first time.

Some of the enlayered plants were kept for some time in earthenware flower pots, but they did not seem to be successful and were then put out on rockeries, when they at once improved and they are now growing well. Three or four of these are in King's House Garden, others are in Lady Swettenham's garden at Bellevue at 3,800 feet elevation.

The elevation of Hope Gardens where the plant is growing is 650 feet, and the rainfall is 53 inches. This is a dry district, and most of the plants in the garden can only be kept alive by constant watering, but the Adenium is never watered. *W. Fawcett, Director of Public Gardens and Plantations, Jamaica.*

BYRAM PARK, FERRY BRIDGE.

ALTHOUGH Byram Park, the residence of Sir John W. Ramsden, is not situated in the most picturesque part of the county of Yorkshire, it possesses many attractive features. The estate has been in the possession of the Ramsden family since 1612, and the baronetcy was created in 1689. The mansion is somewhat rectangular in shape, and at the end, which faces to the south, is the carriage entrance. On the western side there is a wide, open terrace, which is enclosed by a low balustrade wall, at the base of which is a ha-ha or sunk fence, with the deer park beyond. This park forms a most picturesque tract of natural country; its surface is studded with groups, avenues, and single specimens of Oak, Lime, Elm, and Beech trees of all sizes. The present owner of Byram takes a keen interest in all that pertains to woodland, and he is an authority on forestry. In the portion of the park nearest to the mansion no tree is cut down if there is any life in it. Dead branches are carefully removed, and any decayed or decaying places in the tree are filled with cement or covered with sheet-lead to arrest further mischief. Large portions of the park are covered with the Common Bracken (Pteris aquilina) and there are acres of Bluebells which, in the early summertime, present a most glorious spectacle. As befits a mansion with such beautiful natural surroundings, little attempt is made to cultivate summer-flowering plants near to it. The glasshouses and kitchen garden are situated on the eastern side of the residence. The paths leading thereto pass through well-kept grounds that are furnished with fine forest trees, and groups and individual specimens of shrubs in variety. Yews are especially abundant and healthy. I was informed that the owner takes a special interest in these trees. Numerous examples of natural inarching are to be seen on the large Beech trees. One in particular might be fitly described as an example of natural engineering on the cantilever principle.

The walks alluded to pass by the upper portion of a natural lake, views of which are obtained through the shrubs and trees that are planted down to the edge of the water. The lower portions of this lake extend through the enclosed grounds, and about the middle portion it is bounded by a balustrade wall with a broad path on its northern side. On a large grass terrace above it there are groups of Dutch panelling in clipped Yew, some old Cedars of Lebanon, groups of Thuja occidentalis, specimen plants of the Golden Yew, with here and there beds for the accommodation of summer-flowering plants. At the time of my visit Richardia africana, growing in the lake, was in full flower. At the back of this terrace is situated the main range of planthouses. The flowerbeds were in their full beauty; some were occupied by tuberous-rooting Begonias in variety, with a carpeting of variegated Mesembryanthemum beneath them; another was furnished with Dactylis glomerata variegata, mixed with Larkspur Blue Butterfly, and edged with a pink-flowered Verbena. In long borders were seen fine clumps of Fuchsia Riccartonii, others of Skimmia japonica, covered with berries, Pyrus japonica, and Jasminum nudiflorum. The two last-named shrubs are pruned severely each season after flowering in order to keep them dwarf and suitable for their position. There are also several specimens of the Witch Hazel (Hammamelis arborea), which flower annually; also Verbascum olympicum, Astilbe Davidii, besides numerous hardy flowering plants.

The planthouses were erected more than 20 years ago by Messrs. W. Richardson & Co., of Darlington, and they are still in excellent order. The central one is 25 feet in height by 50 feet in length, and it reminds one of the old Orangeries seen in some gardens. It has for a cornice a balustrade of a unique design and of the same pattern as that on other walls near to the lake. At each end of this central house there is a narrow corridor which opens into two three-quarter-span houses, each about 40 feet in length by 20 feet in width. At the west end is a greenhouse which, while full of healthy plants, was not so gay with flowers as I have seen it on several former occasions. A large batch of Begonia Haageana looked very promising. Up the roof, the old, but seldom seen Maurandya Barclayana was flowering freely. The adjoining house is a stove, the central stage of which is filled with a collection of exotic Ferns. A batch of young plants of Ixoras in variety were just coming into flower. The front and end stages were filled with a collection of Orchids. Amongst those in flower were Dendrobium for-

mosum giganteum, D. Phalænopsis (some plants having nine strong flower-spikes), and Cattleya Gaskelliana. Hung up overhead, and partially shaded with Stephanotis, were some very fine plants of Cattleya labiata, growing on blocks of Elder wood. One of these Cattleyas had six strong flower sheaths. Other houses were filled with Anthuriums in variety, including both flowering and foliage species; large batches of Begonia Gloire de Lorraine, Caladiums, and Palms. The roofs were well furnished with climbing plants. A specimen of Allamanda Hendersonii had not fewer than a thousand flowers expanded or in bud. Dipladenia Brearleyana was also freely flowered. On the back walls were plants of Monstera deliciosa, Ixora Colei and I. coccinea, Thunbergia laurifolia, and other suitable plants. On shelves near the ridge were plants of Calanthe Veitchii and C. oculata exhibiting the best of culture.

There are two ranges of fruit houses, four in each range. These were erected by the late Mr. Ormston, of Chelsea, about the year 1860, and they are still in a sound condition. They are lean-to structures, divided into four compartments, each about 40 feet long and 16 feet wide. Six are planted with vines, and two with Peach trees. The early vinery was replanted three years ago, the majority of the vines being of the variety Black Hamburgh. A capital crop of Grapes was produced in this vinery last season. In common with the other vineries here, the vines are planted inside the house, but their roots have a free access to borders outside. One house is planted with Muscat Hamburgh. The crop in this house was a large one. Two other vineries are planted with Muscat of Alexandria and Bowood Muscat, and they produce splendid crops of fine fruit. I was impressed with a specimen of the Lady's Finger Grape, the vine being in full fruit.

In the early Peach house there is a splendid old tree of Violette Hative Peach. Its stem at 3 feet from the ground has a girth of 2 feet. I have on more than one occasion seen fruits weighing 10 ounces picked from this tree. It is intended to remove the trees from the second Peach house for the purpose of replacing the present roof trellising with cross trellising on what I may term the "horse stall" system. The back walls of the Peach houses and some of the vineries are covered with Camellias. One of these is a seedling from C. reticulata crossed with C. Donckelaari. Fortunately there is no mealy bug at Byram gardens, hence the fruit houses can be utilised for housing flowering plants when occasion arises, with no danger of infesting the fruit trees with this pest. A batch of 2,000 Strawberries in pots intended for forcing appeared very healthy. The varieties were Royal Sovereign, President, and Sir Joseph Paxton.

There were many excellent pits and frames, and these were filled with batches of Cyclamen, Primulas, Salvias in variety, Poinsettias, Eranthemum pulchellum, Moschosma riparium Bouvardias, Carnation Winter Cheer, and other winter-flowering plants. There are numerous sunken span pits, each 14 feet in width, with a path up the centre. The side beds are filled with fallen leaves, and they are employed for a variety of purposes.

The necessary garden buildings, including potting sheds, packing rooms, seed room, tool shed, and Grape room are well built and maintained in a state of efficiency. The Grape room, in spring time, contains well-preserved bunches of black and white varieties of Grapes. The stalks are inserted in bottles, through a rubber cap, which keeps the bottles almost watertight. The temperature of this structure is maintained at 50° to 55°, and forms a suitable place for the storing of late dessert Pears; indeed, the flavour of Pears stored in this Grape house is very superior to those housed in the ordinary fruit room.

The kitchen garden contains the fruit and plant houses, and the whole is so well arranged that the one seems to merge into the other. The area of ground available for the culture of vegetables and fruit is limited, hence close and careful cropping is necessary to maintain a constant supply of produce. Culinary Peas succeed exceptionally well; one variety has been grown in the vicinity for more than 50 years, and this was conspicuous for the strength of its haulm and the abundance of its crop. The varieties of Pears include Doyenné du Comice, Louise Bonne of Jersey, Marie Louise, Charles Ernest, Winter Nelis, Nouvelle Fulvie, Josephine de Malines, and Beurré Rance. Apples include Lord Suffield, Cockpit, Ecklinville Seedling, Warner's King, Peasgood's Nonsuch, Bramley's Seedling, Lane's Prince Albert, Pott's Seedling, and Cox's Orange Pippin. The soil of these gardens is a stiff loam resting on magnesian limestone. The gardens have been under the care of Mr. Taylor for the past 20 years. *Yorkshire Gardener.*

FIG. 100.—NARCISSUS "EVANGELINE"; PERIANTH PURE WHITE, CORONA LEMON-COLOURED.

NARCISSUS "EVANGELINE."

THIS new variety of Narcissus (see fig. 100) was exhibited by Messrs. Cartwright & Goodwin, Blakebrook, Kidderminster, at the meeting of the Royal Horticultural Society on March 31. It belongs to the Leedsii section, and the flower, as will be seen on reference to the illustration, possesses first-class form, its broad perianth segments, that are pure white, providing an admirable setting to the lemon-coloured crown, which rises from its centre. The beautiful flowers of the Leedsii Daffodils may be said to combine the purity and refinement of the Poet's Narcissus with something of the vigour and boldness common to those of the trumpet sections.

FLORISTS' FLOWERS.

DAHLIA NOTES.

DAHLIAS, especially when cultivated for the production of exhibition blooms, are seldom planted in the open until the end of May or the beginning of June. Although they are planted at so late a season, it is advisable to prepare the ground in the early spring by digging in a good dressing of manure, and leaving the surface of the soil rough. Autumn manuring is not to be recommended for Dahlias, on account of the long period that elapses before the manure is used by the plants, for the greater part of the manurial properties are then washed away by the winter and spring rains. Deep digging is one of the secrets of success in Dahlia culture, and it is especially valuable if the weather of the following summer should be hot and dry. The manure when dug in deeply is of great value, as at the time the roots reach it the plant requires every possible aid in order to give the best results. Dahlias should be grown entirely by themselves, for it is useless to expect perfect flowers if they are surrounded by other plants, each struggling to secure as much root room as possible. The Dahlia is a gross feeding plant and, broadly speaking, the higher the manurial

treatment the better will be the flowers. Not a few growers have in the past condemned the Cactus varieties of Dahlias for various reasons, but chiefly on account of their bad habit as garden plants. This has arisen from growing unsuitable sorts. A first-class exhibition variety which is much lauded in the nurserymen's catalogues, is not always the best variety for general purposes. There is not the slightest doubt but that the majority of the best habited seedlings are discarded by raisers simply because new varieties are judged on their merits as exhibition flowers. There are, however, many useful kinds which possess a strong flower-stem, and if a good habit is of greater importance to the grower than form of flower, these varieties should be selected. Much has been written respecting the merits of the Pæony-flowered Dahlia, but with their broad, flabby florets they are inferior as cut flowers to the Cactus section, for they wilt very quickly. If they are simply required to form a mass of colour, such as is required for church decoration, they are to be recommended, and are even better for this purpose than the Cactus varieties. For the planting of flower beds, Cactus Dahlias in small batches, intermingled with other plants, or in beds of dwarf-growing sorts of one variety by themselves, are eminently suitable, and they grow very evenly, especially in height. The Pompon Cactus Dahlia promises to become popular when more generally known, as the flowers are suitable for many uses, and especially those that are pure white. The great difficulty in this section is to produce stout, robust-growing plants, as the raisers have found the tendency is towards a weakly plant with a correspondingly weakly flower. Still, there exist some very creditable varieties, notably Mignon Nain, Peace, Coronation, Tomtit, and Gracie.

It is a very common practice to plant Dahlias that are badly pot-bound. This is to be condemned, as the roots not only fail to push freely into the surrounding soil, but in most cases the plants have already become stunted.

If old tubers are divided and potted, it is best to delay the work until the end of April, and instead of packing the pot full of useless tubers, it is far preferable to select one or two with prominent buds. If this is done, they can be potted sufficiently deep to bury the crown under the soil, and then the shoots will not only start away stout and healthy, but they will emit strong, young tuberous roots close to their bases, and these young roots are worth more than any quantity of old tubers. The plants should be planted out before these roots entwine and fill the pot, or they will form a mass from which it will be difficult for any of them to extricate themselves. When lifting old roots in the autumn, it will often be seen that the tubers still retain the shape of the pot, and such plants have generally been failures. Young plants raised from cuttings are not very liable to become pot-bound. Growers are often anxious to obtain early blooms, and the plants are pushed on with a view to this, the gardener believing that the larger the plant at planting-out time, the sooner will the flowering season commence. This is very generally a mistake, as big plants are often "hard," and even if in a growing condition, the check caused by the disturbance at the roots is greater than in the case of a comparatively small one. The larger plant has to wait until its roots get a fresh start, whereas the small plant grows away and quickly passes the other. It is not unusual for large plants to cease growing for some time, and in consequence become very stunted, and then to break from the base and make an entirely fresh start. Young plants growing in 5-inch pots are the best for planting.

One of the worst enemies of young Dahlia plants is thrip, therefore the plants should be dipped in an insecticide before they are finally planted. *Harry Stredwick.*

FERTILITY OF DAFFODIL VARIETIES.

In the case of plants like Daffodils, which take from five to eight years to flower from seed, any information that will help to save time at the start is useful. First of all, it is very desirable at least to know what varieties can be relied on to set seed, or to furnish fertile pollen, and which are partially or wholly sterile. The lists given below are based on experiments made during the last five years. Altogether about 1,000 crosses were made, each variety being separately tried with the pollen of several different kinds, and those that failed to set seed one year were tried again in succeeding years. I have combined the results thus obtained with observations communicated to me by several other raisers of Daffodil seedlings. I am in particular indebted to Mr. H. F. Chapman, Mr. W. C. Bull, and other members of the Kent, Surrey, and Sussex Daffodil Society, and also to Miss Willmott, especially for information as to some of the newer varieties.

Fertility is, of course, very largely dependent on the conditions of the environment—soil, climate, &c.—as well as on constitutional peculiarities, and it would be unsafe to state definitely that this or that variety is or is not fertile. No such dogmatic statement is intended, but inasmuch as the lists are the outcome of a considerable number of crosses and embody the experiences of several raisers under varying conditions, they may, I think, be relied on for practical purposes.

Ajax or Trumpet Varieties (Yellow).—Abscissus,* Countess of Annesley,* Emperor,* Glory of Noordwijk, Golden Spur, Henry Irving, King Alfred,* Maximus, M. J. Berkeley,* Monarch, Obvallaris,* P. R. Barr, Santa Maria are free seeders, and are fertile as pollen parents, those that are starred being especially free.

Admiral Togo, Big Ben, Cabeceiras, Fred Moore, Golden Bell,* Golden Eagle,* Golden Prince, Lord Roberts, Noble, Van Waveren's Giant* are also free seeders, but I have not tried them as pollen parents. Glory of Leiden seems to be quite infertile, both ♀ and ♂ with nearly everybody, but I once obtained a pod containing one large good seed, and I have heard of at least two others who have obtained seed from it. Telamonius plenus is a very shy seeder, but has very fertile pollen.

Trumpet Varieties (Bicolors).—Duke of Bedford* and Weardale Perfection* are very free seeders, and have very fertile pollen.

Empress, Grandis, Horsfieldii, J. B. M. Camm, Mme. Plemp, and Mrs. W. T. Ware are all rather shy seeders; they set seed with certainty when fertilised by such varieties as Mme. de Graaff and Duke of Bedford, but average less than 10 seeds to a pod. Horsfieldii and Mme. Plemp are rather better seeders than the others, and are even free with some. Their pollen seems generally quite infertile (except Mme. Plemp), but I have obtained a few pods (containing only two or three seed) with the pollen of Horsfieldii and also of Victoria. Lettice Harmer seeds freely. Victoria sets seed freely with the pollen of Duke of Bedford, but proved barren with every other variety (13) tried, though a few seeds have been obtained by others with pollen of Mme. de Graaf and Triandrus calathinus. Sentinel is quite infertile ♀ and ♂.

Trumpet Varieties (White).—Albicans, Cernuus, Cernuus pulcher, Moschatus, and Pallidus præcox are good or fairly free seeders and pollen parents. Mrs. Camm, Mrs. Thompson, and Princess Ida are free seeders. Mme. de Graaf is a moderately free seeder, and is one of the most fertile of pollen parents.

Incomparabilis Varieties.—Artemis, Dorothy York, Lady M. Boscawen, Mabel Cowan, and Princess Mary* seed fairly freely; Beauty is a shy seeder; these I have not tried as pollen parents. Great Warley is freely fertile both ♀ and ♂. Lucifer seeds very freely, but its pollen is infertile. Blackwell and Lulworth are only moderately fertile, both ♀ and ♂ with me and others; with some, Blackwell is quite barren, and, again, some find it a fairly free seeder (being an early variety, this varying experience is probably due to climate). Will Scarlett is a very shy seeder, and C. J. Backhouse has never set seed with me, but both these varieties have good pollen. Gloria Mundi is quite infertile ♀ and ♂. Sir Watkin has never set seed with me (15 crosses), but others have found it fertile, both as seed and pollen parent, and with some it seeds freely.

The Leedsii Section.—Lilian, White Lady, and White Wings are free seeders; Mrs. Langtry and White Queen are shy seeders; I have not tried these five as pollen parents. M.M. de Graaf is a very shy seeder, and its pollen is infertile. Beatrice and Gem do not set seed, but have moderately fertile pollen. Minnie Hume is an uncertain variety, seeding freely some years and quite infertile others.

The Barrii Section.—Albatross, Dorothy E. Wemyss, Flora Wilson, and Mrs. C. Bowley* seed freely, and the latter is also a good pollen parent. Crown Prince and Seagull are shy seeders. Barrii conspicuus and M. de Vilmorin are quite infertile ♀ and ♂.

The Burbidgei, Englehearth, and Bernardii Sections.—These varieties are said to be generally good seeders. I have only tried a few. Beacon, Blood Orange, and Southern Star seed fairly freely, but, on the other hand, Firebrand, John Bain, Rosalind, and Sequin are shy seeders. Firebrand is the only one I have tried as pollen parent, and it is fertile, but very slightly. Incognita is fertile, both ♀ and ♂. Bernardii H. E. Buxton has proved infertile ♀ and ♂ with me so far, but I have only tried it one year. Johnstonii Queen of Spain and N. odorus are quite infertile ♀ and ♂. Nelsonii Major has seeded with me with pollen of Triandrus calathinus; its pollen is quite infertile.

Varieties of Poeticus.—I have found all the Poeticus varieties free seeders and good pollen parents (and Mr. Chapman, who grows most of the new varieties, confirms this), except P. grandiflorus, which has never seeded with me (14 crosses), but its pollen is fairly good.

Narcissus Species, &c.—Triandrus albus and calathinus seed freely, and have very fertile pollen; Cyclamineus, Jonquil, and Corbularia Clusii are fairly fertile ♀ and ♂, and Corbularia conspicua is shy. This refers to when they are crossed with Daffodil varieties; they all seed freely with their own pollen. *A. J. Bliss.*

CROCUSES IN A LONDON PARK.

The illustration at fig. 101 shows the beautiful effect that is obtained by planting bulbous plants on grass slopes or dales in the more secluded spots of a public garden or park. It represents a waterside slope in one of the London public parks, planted with Crocuses in batches of one colour, including purple, yellow, rose and white. The large breadths of these flowers seen in Regent's Park in spring time are always a popular feature. Unfortunately the flowering period is short, especially when several warm days succeed at the time they are in bloom. The worst enemy of the Crocus in town gardens is the sparrow, which seems to have a preference for the yellow blooms. Black cotton intertwined and kept in position by short sticks serves to ward off their attacks somewhat; the sticks should be neat and thin, in order that they may not be obtrusive. A system of planting Crocuses in grass to be recommended is to place them in separate batches of one colour around the base of a tree. *A. J. Hartless.*

VEGETABLES.

FORCED EDIBLE PEAS.

In order to be successful in the cultivation of Peas under glass it requires a little more than ordinary care. This is especially the case if pods are required for picking early in April. I am not referring to those grown early in Guernsey under conditions so much more favourable to them, but those required from the various gardens in England in either town or country. The many varieties of Peas now on the market only add confusion to growers when a selection of what is best for a given purpose is required. It may appear strange, but it is none the less a fact, that some of the early varieties of Peas that are so desirable in the open are almost failures as regards profitable cropping when grown under glass. Peas of the Gradus type, of which there are several, and are so excellent for general cultivation in the open, are not satisfactory under glass, and after having tried a good many types, it is evident that some of them are more easily fertilised than others. Generally speaking, too, the dwarfed sorts with dark-leaved branches and short internodes are not so profitable or so easy to grow as those attaining a height of from 3 feet to 6 feet. Where Peas are grown in the same position in the soil under glass for several seasons in succession, some care is necessary as regards suitable food for sustaining the plants until such time as the pods are properly matured. Soil under glass lacks the silky texture that is so cheaply obtained in the open by the ameliorating influence of frost, rain, and winds, and even the modest earth worm assumes a bilious hue under his new conditions. With Peas under glass, as in the open, moisture plays a very important part, and in preparing the soil for sowing or planting from pots, which latter is the more economical, because the houses either contain late Tomatos or Chrysanthemums, and the Peas may conveniently be kept in the pots for eight to ten weeks in cold frames previous to setting out, we have found nothing so good as well-rotted hot-bed manure, supplemented by a little bone-meal and wood ashes. Of course, water plays a very important part in the successful management of Peas under glass, and only under cool, moist conditions of the soil can success be achieved. Previous to the flowering, after very bright days, a very light dewing with tepid water will do much good; also after the pods are set and swelling freely. Up to this stage quite cool treatment is necessary, or the internodes will be long, the flowers weak, and the crop a poor one. I have found it good practice to remove the growing point when the maximum number of pods are set. This concentrates the plant's energy on those remaining, and it is at this stage that more warmth may be given to hasten maturity. A light sprinkling of nitrate of potash or nitrate of soda may, with advantage, be given when the pods are swelling, just to give that glaucous bloom so much admired and which is a point in favour of better returns when placed upon the market. I am often at a loss to understand, apart from those grown entirely under glass, why more Peas are not raised early in the season for transferring into the open, because the system has so many advantages. Safety from birds, mice, and no fear of decaying seeds in cold, wet soils are reasons sufficient to encourage all who are anxious to obtain this excellent vegetable as early as possible. Peas raised in pots are robbed of a little luxuriance of growth early in the season. This is an advantage, as they are thrown earlier into bearing, which is the chief object aimed for. Neither is it always necessary to have the protection of walls, as is often thought. Plenty of twiggy shoots and a soil not too rich in organic remains will be found to suit Peas for early use; also a fairly consolidated soil if it is naturally of a

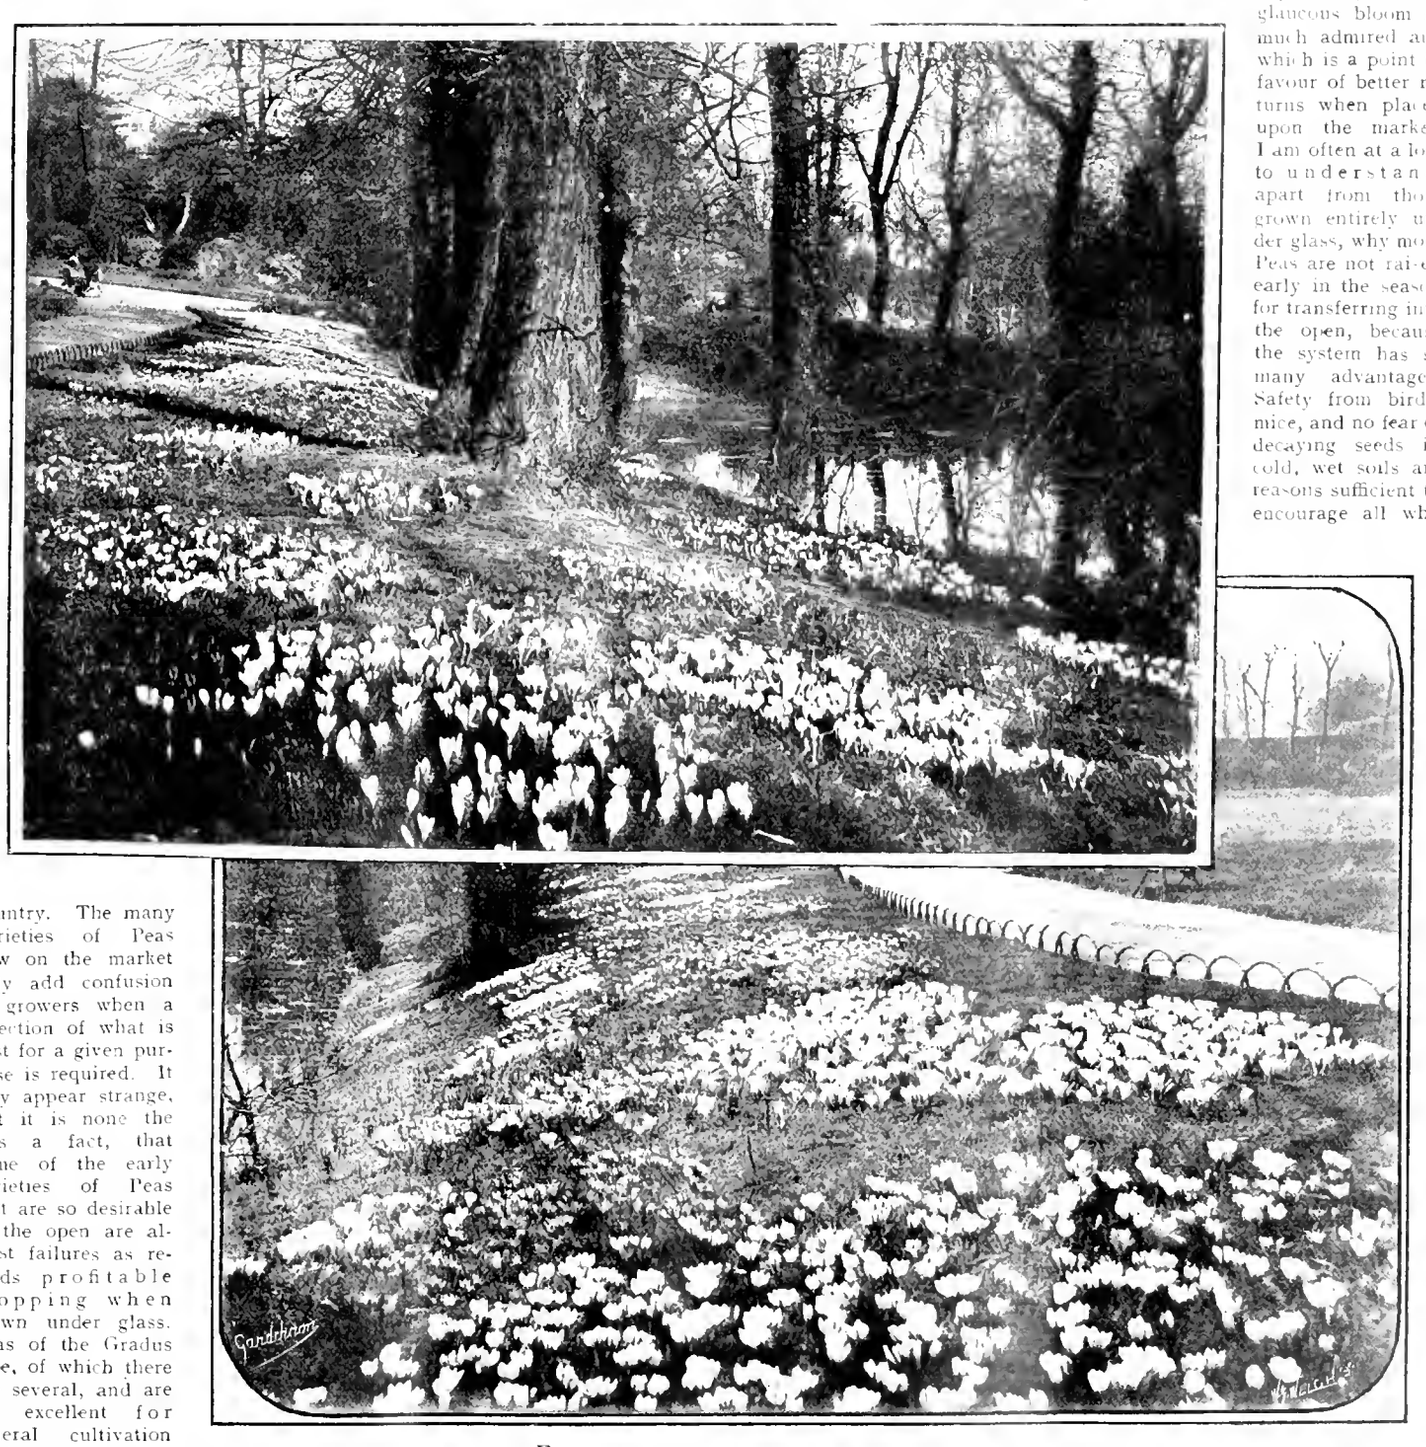

Fig. 101.—Crocuses in Waterlow Park, London.

light, sandy character. Amongst the most prolific varieties for growing inside are Duchess of York, Duke of York, Telegraph, the dwarfer stock of Duke of Albany, Thomas Laxton, Ideal, Empress of India, and May Queen (if objection is not taken to a pale pod). The round-seeded varieties like William I., The Pilot, a pod as large as a Marrowfat, or Bountiful fill well, and of the dwarfer type, Little Marvel is very reliable. *Charles Foster, University College, Reading.*

The Week's Work.

FRUITS UNDER GLASS.

By T. COOMBER, Gardener to LORD LLANGATTOCK, The Hendre, Monmouthshire.

Newly-planted vines.—Upon each young vine it will be necessary to select a suitable leading shoot to form the foundation of a permanent rod. This should be carefully trained to a Bamboo cane or similar support, and which can be secured in position on the trellis for this purpose. When these growths have grown to a length of about 3 feet, varying more or less according to their strength, they should be stopped, and all the lateral shoots must be stopped after the first leaf, the principal leaves being carefully preserved. This will cause the shoots to strengthen and thus develop their buds. After stopping the main shoot, let another shoot be selected from the top of the shoot thus stopped. This secondary leading shoot may be allowed to grow until it reaches the top of the house. These shoots will be cut off at the winter pruning, but in the meantime they may be allowed to make a few lateral growths, as the presence of these will stimulate root action. Care must be taken not to overcrowd these lateral shoots. Vines which have been planted one or two years will need similar treatment as regards training to that I have just described, as also will young rods which are being raised for replacing exhausted canes of old vines. By removing old rods and allowing the plants to develop young canes increased vigour may be easily imparted to old vines. The amount of crop that young vines which have been planted one or more years should be allowed to ripen will depend on the vigour of the individual plants. Give close attention to the ventilation of the house and endeavour in every way to encourage short-jointed growths. No root stimulants will be needed at present if the borders have been properly constructed.

Fig trees in pots.—Upon trees started at about the end of November the fruit will be approaching its final swelling. Afford the roots a top-dressing of loam and manure and apply plentiful supplies of liquid manure, which should be made tepid before use. Syringe the trees thoroughly twice a day in bright weather, and if thrip or brown scale insects should appear, carefully sponge the leaves with soapy water. When the fruits show signs of ripening expose them as fully as possible to the influence of the sun, and thin out and stop the shoots as may be necessary to admit sufficient light. Increase the amount of ventilation in favourable weather, and leave the ventilators open a little during the whole of the night. Less atmospheric moisture will be needed at that stage, but it should not be decreased sufficiently to affect the health of the trees or the development of the second crop of fruits. Let the temperature at night be 65°.

Melons in frames.—Melons may be satisfactorily grown in frames or pits during summer. Preparations for growing them in this manner should be made at the present time. Fermenting materials should be collected and made into beds in the same manner as was described on p. 156 for Cucumbers. Place thin turves over the hot-bed and build a firm ridge on the turves, forming the ridge of stiff loam, with some crushed mortar rubble, leaf-mould, or wood ashes mixed with it, and a little dry soot. This bed should be formed rather nearer the back than the front of the frame. Raise the necessary number of plants in small pots, and when the heat of the hot-bed has declined to 80° or 85° plant them on the ridge, putting two plants under each light at equal distances apart. Stop the plants at the third rough leaf and train two shoots from each plant, one towards the front and the other to the back of the pit, stopping these when they reach the limit of the pit. Ventilate the frames carefully upon sunny days and close the ventilators early in the afternoon, at which time the plants and surface of the bed should be syringed with tepid water. Protect the frames at night with a covering of mats.

PLANTS UNDER GLASS.

By THOMAS LUNT, Gardener to A. STIRLING, Esq., Keir, Perthshire, N.B.

Chrysanthemums.—Plants which are cultivated for supplying large blooms should now be ready for re-potting into pots 6 inches in diameter. Employ a slightly heavier compost than that which was used at the last potting. It may be formed of fibrous loam, leaf-mould, lime-rubble, wood ashes, sand, and horse-dung. This latter should be used in the same condition as it is prepared for a Mushroom bed. A sprinkling of bonemeal may also be added to the compost. Care should be taken to see that the plants have formed roots which reach the sides of the pots before they are re-potted. After the re-potting has been done, place the plants in an unheated frame containing an ash bottom; pay careful attention to ventilation, and prevent cold draughts from reaching the plants. Syringing may be done each morning and afternoon in bright weather. If the presence of green-fly can be detected, let the plants be dipped into extract of quassia. During the present month attention should be given to pinching and stopping the shoots for securing second crown blooms, but no definite dates can be given for doing this, as it has been proved again and again that locality-method cultivation and nature of soil have a very wide influence on this matter. When a plant has been recently stopped, rather less water should be given the roots until growth has recommenced. Pinching and potting should not be carried out at the same time, because each operation causes a check to the plant. Before re-potting a plant the roots should be examined to see that the soil is in a medium state of moisture, because it is inadvisable to apply water for a period of two or three days immediately following the process of re-potting. When placing the plants in the frame it will be necessary to see that the tops will be near to the glass, and also that there is sufficient space left between the plants. Each specimen should be turned round towards the sun once a week. Attention to these minor details, and especially to securing the buds at the proper date for each variety is necessary if a large measure of success is to be attained. For guidance another season, a record should be taken of the dates on which all the operations I have mentioned were carried out in the case of each variety, and notes made of the effects, whether good or bad. If dull weather should occur during the time the plants are in the unheated frames they may suffer an attack of mildew, in which case the foliage should be dusted with flowers of sulphur.

Rondeletia speciosa.—This is a most useful species for flowering in the stove in autumn and winter. It succeeds well if trained on a wall or on the roof, continuing to flower freely if kept growing in an upright position. If it is required for forming a specimen plant on a balloon-shaped trellis, the shoots should be started from the base slightly on the incline, always training them upwards, as if allowed to hang with their shoots pointing downwards they cease to flower and sometimes die back to an upright joint. The species succeeds well in a compost consisting of loam, peat and sand in equal parts. Use clean pots, provide them with liberal drainage, and in the process of potting make the compost very firm.

Statice profusa.—This plant is now starting into growth, and the stock may be increased by layering the growths, as is done in the case of Carnations. Use a compost of loam, peat, and silver sand, and press this material firmly about the layer. Roots will soon be formed, and the layers may then be severed and potted into small pots, using rather more peat than loam. They should be afforded a heat of 65° until they are freely growing. Remove all flower-spikes and encourage growth in every way possible. Old plants may be given liberal dressings of artificial manure during the season of growth, and the flower-spikes should be picked off until the plants are needed to bloom. These old plants need a cool atmosphere, but should be shaded from bright sunshine.

PUBLIC PARKS AND GARDENS.

By JAMES WHITTON, Superintendent of the Parks and Open Spaces in the City of Glasgow.

Bandstands.—While many people maintain that bandstands are abominations in parks, and that they frequently mar the music more than aid it, these structures have come to be recognised as part of the necessary equipment, and have to be studied accordingly. It must be admitted, however, that many of them seen in public parks are inartistic in design and inharmonious with their surroundings. When it has been decided to erect one, the first point for consideration is that of the selection of the most suitable site available for the purpose, but, unfortunately, bandstands are by some garden architects made too much a special feature in park designs. For instance, a bandstand is sometimes placed at the intersection of cross-roads, where its utility is impaired by the noise of the passing traffic, which seriously interferes with the enjoyment of those who wish to listen to the music. At another time it is set on an eminence and, although it may be an architectural feature in such a position, it is useless for the special purpose such structures are erected. The presence even of a moderate wind is sufficient to destroy the effects of the finer passages of the music, and the listeners are subjected to discomfort in unfavourable weather. I have personal experience of several examples such as I have described.

The best position.—No hard-and-fast rule can be laid down, as local circumstances must to a great extent govern the situation. The nearest approach to an ideal site suitable for this country, in which the climate is proverbially variable, is that afforded by a fairly open grass-covered space, a sufficient distance away from the stream of traffic, and which will accommodate an audience amounting to 10,000 persons. One in a natural depression, from which the ground rises on all sides, and is surrounded with a border or belt of trees and shrubs. A natural amphitheatre of this description provides the necessary shelter and quietness, and affords the audience an opportunity of seeing the performers as well as hearing the music. Where the situation lends itself for the placing of a bandstand in a position where, while serving its primary purpose, it will also form a feature of some value in the park architecture, the opportunity need not be thrown away, though it may prove to be a somewhat costly form of park adornment, and is only to be recommended in cases where private individuals desire to make such a gift to a public garden.

The best form of bandstands.—Bandstands in this country are usually circular or octagonal in form, and have a roof supported by iron or wooden pillars. This canopied pattern is open on all sides, and possesses certain advantages. There is, however, another type which is very popular on the Continent, especially in Germany, which, for convenience, I call the "shell" pattern. We have two such structures in Glasgow, and many bandmasters and other musicians speak highly of their acoustic properties. They are somewhat more expensive to erect than the canopied stand, but they are also more suitable for certain situations. Were we Britons less conservative than we are, I think the shell pattern would be adopted in numerous cases. Whilst a bandstand ought always to be a structure of dignified appearance, excessive elaboration of detail and ornamentation is not to be recommended, and the painting should be carried out in subdued colours.

Music-stands.—Most bands carry with them music-stands, which are usually of a folding type, being made as light and portable as possible, but occasions arise when these are forgotten, or owing to some other reason fail to serve their purposes. We therefore undertake to equip each bandstand with music-stands designed so as to best meet our requirements. The stands have a flat, three-pointed, cast-iron base, in which a tubular stem is fixed, fitted with a thumbscrew. The music-board is attached to an iron rod, which is slipped into the tube, and can be raised or lowered to suit the musician. Spring clips are fitted on the board to keep the music sheets from being displaced by wind. These stands cost about 7s. 6d. each, but the short time they require in setting up, and the little space they need for storage, render them preferable to other patterns which we have tried.

THE FLOWER GARDEN.

By W. Fyfe, Gardener to Lady Wantage, Lockinge Park, Berkshire.

Trees and shrubs.—Any recently-planted trees and shrubs should be sprayed frequently with water during dry weather. This is better than applying excessive quantities of water to the roots, especially at this season, when the soil is cold. Examine all the specimens and see that they have proper supports, and that the ties are in a perfect condition.

Box edging.—These should now be trimmed by clipping them level with a pair of shears, making them the desired shape. If there are any gaps, these must be made good by planting fresh plants. Box does not thrive as an edging in all soils, therefore it is useful to remember that there are other plants that may be used for forming green edgings. These include Armeria maritima (common Thrift), Gentiana acaulis, and Saxifraga umbrosa, any one of which may be selected when it is found that it will thrive in a particular garden.

Grass verges.—These may now be trimmed with the edging iron, but care should be taken to use a line and measurement rod, it being unsafe to trust to the eye for maintaining parallel lines. Beat and roll the grass before commencing to cut it, and if the edging is out of condition in some places cut away the turf about a foot wide and move more turf forward to the line; the cuttings from other portions may be utilised to fill in behind the turf which has been brought forward to the line.

Hardy herbaceous plants.—Examine such species as Phlox, Aster, and Sunflower, which are in the habit of producing many more shoots than are desirable, it being necessary to remove a considerable number before they suffer injury from overcrowding.

Bedding Pelargoniums.—These may now safely be transferred to unheated frames for hardening off. Afford them protection at night by placing mats over the frames, and carefully ventilate the frames during the day. If sufficient stock has not already been raised, propagation may be still continued.

The rockery.—This portion of the garden will need to be made tidy before the plants make further growth. Fern fronds that were left to add to the appearance during winter may be cut off, and the surface soil stirred. A light top-dressing of leaf soil should be afforded. Many plants require frequent attention to keep them within proper bounds; such subjects as Saxifragas and Sedums should be allowed to grow in clumps extending to not more than a yard in diameter. Sometimes Lichens and Mosses spread quickly over the stones that form the rock garden, and their presence is not disagreeable, provided they do not encroach on the space allotted to the Alpine plants.

THE ORCHID HOUSES.

By H. G. Alexander, Orchid Grower to Major G. L. Holford, C.V.O., C.I.E., Westonbirt, Gloucestershire.

Oncidiums.—The species that flower in the spring and early summer, such as O. Marshallianum, O. olivaceum, O. Phalænopsis, O. microchilum, &c., are now developing flower spikes, and such plants as show signs of this should be afforded a moderate supply of water, until the plants cease to flower. When that stage is passed, rather less will suffice for a time, as the plants will need a short rest before starting into growth again. The late summer and autumn-flowering kinds as O. varicosum, O. Forbesii, O. crispum, O. dasytyle, O. tigrinum, O. Mantinii, O. Gardneri, etc., having rested since they flowered last year, are now making new growths. They will soon push forth young roots from their base, and when these are observed any re-potting or top-dressing that may be necessary should be given immediate attention. A suitable rooting medium for these plants is one consisting of equal parts Polypodium fibre, Osmunda fibre, and sphagnum-moss, all these materials being chopped up and mixed well together. Let the pots be well drained, make the compost moderately firm about the roots of the plants, and surface with clean sphagnum-moss. These Oncidiums are all inmates of the cool-intermediate house, and are best grown in pans suspended from the roof. Great care must be exercised in watering the roots during their early stages of growth, otherwise the new growths will sometimes damp off. Later on, when the plants are rooting freely and developing pseudo-bulbs they may be given a plentiful supply of water, and the foliage may be freely syringed during favourable weather. O. ornithorhyncum also thrives well in a cool intermediate temperature. Afford these plants fresh rooting material if necessary as soon as the new growths are a few inches high and are about to produce their thread-like roots.

Dwarf-growing Lælias.—L. prestans, L. pumila, and L. Dayana are easily cultivated and free-flowering species. The plants should be grown in small, shallow pans suspended in the cool intermediate house, where plenty of sunlight can reach them. The season has arrived when the plants show renewed activity, and any necessary re-potting or top-dressing should be carried out forthwith. My remarks in a recent calendar on the preparation of a compost for Cattleyas and the operation of potting them will apply to these plants. It is always well to bear in mind that newly-potted plants are best accommodated on the stage for a time, where they can be afforded shade, and be frequently sprayed over and damped between, this treatment helping them to re-establish themselves.

Lælia Jongheana.—This species and its hybrids, Lælio-Cattleya Sunset, L. c. Olivia, L. c. Baroness Schroder, etc., form a very desirable section for making a display of flowers during the spring months. As these plants produce their flowers on growths which are only partially developed, a plentiful supply of water to the roots should be given, even after the flowers are removed, until such time as the pseudo-bulbs are complete. Afterwards, while the plants are resting, give sufficient only to prevent shrivelling of the pseudo-bulbs, and keep the roots healthy. The best time to give these plants new rooting material is shortly after the flowering stage, when new roots are being produced from the last-made growths, treating them as advised above for other dwarf-growing Lælias. The plants grow best when suspended in a light position at the coolest end of the Cattleya-house.

THE KITCHEN GARDEN.

By E. Beckett, Gardener to the Hon. Vicary Gibbs, Aldenham House, Elstree, Hertfordshire.

Vegetable Marrows.—Seeds which were sown according to the directions previously given ought by now to have made good, sturdy plants, and be ready for planting out in their permanent quarters on very mild hot-beds. Such plants should yield good crops of fruit by the middle of next month, and these are sure to be appreciated when vegetables generally are none too plentiful. Keep the growths well pegged down, and early in the afternoon syringe the plants with tepid water and close the frames. Any vacant spaces in the greenhouse or cool orchard-houses may be well utilised by placing a few plants in 12-inch pots and training up the growths near the glass. Such varieties as Moore's Cream, Pen-y-byd and Perfection answer splendidly to this form of treatment. Make another sowing singly in small pots for furnishing successional supplies.

French Beans.—Little difficulty will now be experienced in securing a plentiful supply of these if the conditions are favourable. An intermediate-house will suit them well if the plants are elevated near to the glass. Feed them liberally with manure water, and syringe the under side of the foliage with clean, tepid water twice daily. Make one more sowing in 8 or 10-inch pots, and at the same time sow a few dozen seeds singly in 3-inch pots for raising plants to plant out in cold frames. These will be found extremely useful to form a connecting link between those cultivated in houses and those out-of-doors. Ne Plus Ultra and Canadian Wonder are two of the very best varieties for this purpose.

Mushrooms.—Successional beds may now be made up in the Mushroom-house, in caves, cellars, or any cool shed, or under the shade of a north wall. Failing any of these situations, choose a cool place in the open garden. Beds which are in bearing should not be unduly forced. Maintain the house at an even temperature of from 50° to 55°. The beds will continue to produce Mushrooms for a much greater length of time, and the quality of the Mushrooms will be much better than if they were forced more severely. Any beds which show signs of exhaustion will be much benefited if a good drenching of farmyard liquid is applied in a tepid state. The paths should be damped down also with manure water.

Winter Greens.—The main sowing should now be made on ground which has not previously been occupied for two years with any of the Brassica family. Choose an open site on ground which has not been freshly manured. The seed should be sown thinly broadcast on neatly-prepared beds; I much prefer this plan to sowing in drills. Where land is addicted to clubbing, give a thorough good dressing of finely-sifted cinder ashes, and net the seed beds securely against birds, the greenfinch especially having a particular liking for all Brassica seeds. Where garden mice abound, means must be taken to trap or destroy these.

Lettuces.—Continue to plant out any which have been raised and pricked out in boxes under glass. No better site can be found for them than the centre of the ridges between the Celery trenches. Sow seeds once a fortnight, selecting both Cabbage and Cos varieties to maintain a continuous supply.

Celery.—The principal and main sowings should now be ready for pricking off into skeleton frames, or a south border where slight protection can be afforded for a few days after the planting. Make the surface very firm, and prick out the seedlings, putting them at 3 inches apart all ways.

THE HARDY FRUIT GARDEN.

By F. Jordan, Gardener to The Dowager Lady Nunburnholme, Warter Priory, Yorkshire.

Apricot trees.—In northern districts such as this, it has not yet been necessary to examine the borders of wall trees owing to the frequent rains that have fallen. On light soils, however, especially in gardens where the walls are provided with fixed copings, it will now be necessary to apply a good soaking of water, assuming that the borders are perfectly drained. This is a very important matter in dry districts, and any newly planted trees will need extra care in this respect, failing which they would be liable to perish. Apply a mulch over the roots of all trees after water has been given, this being particularly necessary in cases where the trees have been worked upon shallow rooting stocks. Should the weather continue wet and cold, it may be necessary in certain districts to delay applying such mulches until a little later in the season. Keep a look-out for the Apricot maggot as soon as the trees pass out of flower, for at that stage they generally commence to feed upon the young leaves, which become rolled and twisted in consequence. Remove all the maggots by handpicking and burn them, or having found them in the leaves pinch the leaves between the finger and thumb, thus crushing the maggots.

Strawberries.—Take advantage of a dry day to clean the surface of the ground of all weeds and runners, after which it may be hoed over. Apply a dressing of soot and freshly slaked lime to destroy slugs, but do not coat the crowns with the soot and lime. The beds may afterwards be mulched with liquid from the stables. If the old beds have not been previously mulched with manure, apply a dressing of some chemical manure which contains a good proportion of potash. If it is intended to form fresh plantations by planting out Strawberries which have already been forced in the houses, such plants should first be hardened off carefully in frames. In the meantime they should be kept perfectly free from mildew and red spider. These early plants if treated properly may be depended upon to produce a moderate crop of fruits in the autumn, or if planted in frames they may be made to fruit in August. Later plants which have not been subjected to severe forcing are preferable for forming permanent beds.

Need for hoeing.—At this season of the year when the seeds of numerous weeds are at the point of germinating, an infinite amount of good may be effected by frequently stirring the surface soil with the hoe, as this will have the effect of preventing such seeds from growing. For purposes of aeration of the soil hoeing is likewise beneficial to the trees.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, APRIL 13—
United Hort. Ben. and Prov. Soc. Com. meet.

TUESDAY, APRIL 14—
Royal Hort. Soc. Coms. meet. Brit. Gard. Assoc. Ex. Council meet. Nat. Rose Soc. Com. meet.

WEDNESDAY, APRIL 15—
Roy. Caledonian Hort. Soc.'s Spring Sh., in Waverley Market, Edinburgh (2 days). Kent, Surrey and Sussex Daffodil and Spring Fl. Soc. Sh. at Tunbridge Wells.

FRIDAY, APRIL 17—*Good Friday.*

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich = 46.8°.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, April 8* (6 P.M.): Max. 57°; Min. 35°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London. *Thursday, April 9* (10 A.M.): Bar. 30; Temp. 49°; Weather—Fair.

PROVINCES. *Wednesday, April 8* (6 P.M.): Max. 52° Ireland S.; Min. 48° Lancaster.

SALES FOR THE ENSUING WEEK.

MONDAY—
Hardy Bulbs and Plants, Lilies, &c., at 12; Roses at 1.30, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

TUESDAY—
Clearance Sale of Greenhouse Plants at The Gardens, Hedsor, Bucks., by order of Lord Boston, by Protheroe & Morris, at 1.

WEDNESDAY—
Herbaceous and Border Plants, Lilies, Hardy Bulbs, &c., at 11.30; Roses at 1.30; Palms, Azaleas, &c., at 5, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

Ergot of Rye in Russia.

That the grains of many different grasses are frequently found attacked by the destructive fungoid disease known as ergot is a matter of common knowledge; but it is not so generally known that the ergot which attacks the Rye has become, especially of late years, such an important article of commerce as to produce in Russia alone an export article valued at nearly £17,000 in 1906.

Ergot is usually described in books on pharmaceutical subjects as the sclerotium, or resting stage of a fungus (Claviceps purpurea), found on the Rye, and the countries of production are given as Spain, Russia, and Germany. Ergot contains about 30 per cent. of a fixed oil, besides the alkaloid ergotinine, in the following proportion in the different kinds: Spanish about 0.3 per cent., and Russian and German about 0.2 per cent., and in addition sphacelinic acid. Although ergot contains poisonous principles, it is of valuable service in medicine.

Much interesting information on this peculiar product in Russia is given in the *Pharmaceutical Journal* for February 29 last, p. 247, from whence are gathered the following facts: Rye being the staple cereal of Russia, the annual crops are enormous, hence the very large quantity of ergot is produced. This is not the result of any effort in cultivation, for, on the contrary, everything possible is done to prevent its growth, it being regarded as a pest and a source of disease, from which many thousands of Russians fall victims during the periodical epidemics of ergotism that devastate the country, in consequence of the people feeding on ergotised Rye. It is said that sometimes as many as ten of these ergotised grains may be seen in one ear.

During the harvesting of the Rye quantities of the ripe ergots fall to the ground, where the spores germinate and freely infect the new crop of Rye. Rainy districts and wet seasons are favourable to the development of the ergot, and the size of the "horns," as they are called, depend to some extent on the size of the ear than on cultivated Rye, being much larger than those growing on a wild form.

The collection of the ergot is made during the harvest time, and the fungus is separated from the grains in the process of threshing. It is said that the question has been frequently raised in Russia as to whether it would be possible to separate the ergot from the Rye during the period of growth, not for the sake of keeping the ergot, but for destroying it, but nothing has hitherto been done in this direction. After the ergot is separated from the grain it is dried, but this is done in a very imperfect manner, being simply exposed to the air, the Russians having no system of artificial drying; consequently, if kept by the peasants for any time, it frequently becomes coated with a mould, when it is considered useless; the people, however, have some means of heating it with oil and then palm it off as fresh crop, which accounts for the fact that much ergot, which is apparently sound, is often destitute of any therapeutic value.

The chief Russian trading centres for ergot are Tomsk and Omsk, Siberia, and Viatka, Samara and Bessarabia. The peasants collect it in small parcels of about 36 lb. (English), which they sell to the local dealers, and the dealers, after amassing a supply of about five times this amount, bring it into town, where it is purchased by the pharmacists and exporters.

In addition to the palming off of old ergot as fresh, the exporters in the centre of Russia are not always to be trusted, since their samples are frequently not true indications of the bulk. It is only after the ergot has reached the large exporters at the seaports that the samples can be relied upon; further, it is difficult to buy a large quantity from one exporter only. Large quantities can only be obtained from the houses in towns like St. Petersburg, Riga, Libau, or Odessa.

The best ergot is obtained in South Russia, and though it is small, it contains more alkaloid than the larger Siberian kind.

The growth in the export of ergot from Russia has been increasing for some years past. In 1900 it amounted to about 45 tons, of the value of a little over £2,000. In 1902, 65 tons were exported, valued at £3,420. In 1905, 102 tons of the value of £3,788, and in 1906 the quantities and values had leaped to 215 tons, and the value to £16,900. The prices recently quoted for ergot at the London drug sales has been 11d. per pound for Spanish, and 10d. to 10½d. per pound for good Russian.

Referring to the prevalence of ergotism in Russia, it is stated that exact statistics are furnished showing the death rate, and the Russian Government is said to be fully alive to the perils arising from the presence of the fungus; but notwithstanding all the precautions, epidemics continue to rage from time to time. In 1854 an epidemic broke out in the Crimea among the soldiers, in 1862 in Finland, and in various Governments in 1865, 1872, 1879, and 1880. In 1888 there were many cases of ergotism in the Government of Poltava, where many people died, lost a hand or foot due to gangrene, or became paralysed for the rest of their lives; and since this date several severe epidemics have occurred. It has been suggested that as a preventive to these visitations, the Rye, together with the ergot, should be kept in a granary for a year, by which time the action of the ergot would be practically nil, and then only should the Rye be used. It is observed that this would be a difficult course to pursue, especially in years of famine.

OUR SUPPLEMENTARY ILLUSTRATION depicts a portion of an Australian garden with a water scene in the foreground, at Leura, the residence of T. H. PAYNE, Esq. The scene might be taken as almost typical of an English garden, except for the different character of the vegetation, but the view of the residence at fig. 102 with its broad verandah, is that of a style very common in the warmer Colonies. The gardens have been laid out in the methods common in England, and the gardener, Mr. JOHN W. BLACKBURN, who has been largely responsible for their design, was previously employed in some noted gardens in this country, including those at Scone Palace, Dalmeny Park, and Headford House, before journeying to Australia. The lake is surfaced with Nymphæas, whilst the clump of Papyrus (P. antiquorum) indicates the advantage in climate which these gardens possess over our own. The bank of stone work abutting on the water on the right hand of the picture is planted with Cactaceous plants. The circular Rose bed forms a fine setting to the broad lawn, and in the background is a belt of trees which includes many indigenous species and Palms. Several photographs, besides the two we reproduce, were kindly sent us by Mr. BLACKBURN, and in one of these is shown the kitchen garden, with the glasshouses. These include vineries, Orchid houses, and Melon pits, just as are usually provided in country establishments at home. Another illustrates a handsome conservatory in a setting of flower borders, with a profusion of ornamental shrubs and trees surrounding it. Mr. BLACKBURN, who went to Australia in 1890, has had the care of Leura Gardens since that date.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the committees will be held in the Hall in Vincent Square, Westminster, on Tuesday, April 14. In addition to the usual exhibits, there will be a special exhibition of Narcissus, for which Messrs. BARR & SONS' silver vase and other prizes are offered. At 3 p.m. a lecture on "Hardy Cacti and other Succulents" will be delivered by Mr. E. A. BOWLES, M.A., F.L.S.

The Surveyors' Institute.—The next ordinary general meeting will be held on Monday, April 27, at 4 p.m., being the second of the two afternoon meetings arranged for the convenience of the country members, when a paper by Mr. Kenneth J. J. Mackenzie (Associate), Lecturer on Agriculture, Cambridge University, entitled "The Agricultural Education of the Land Surveyor," will be read. The Council have accepted an invitation from the Kent Provincial Committee to hold the next country meeting at Dover on May 21 and 22. Arrangements have been made for visits to various works and places of interest, including the harbour works and the castle. The following excursions have also been arranged: (1) to Calais and Boulogne, returning to London via Folkestone; (2) to Canterbury Cathedral and Chatham Dockyard.

English-Grown Shrubs for Germany.—Messrs. Smith & Sons, Darley Dale Nurseries, have despatched 1,500 specimen shrubs to Potsdam, where they will be planted in the grounds about the Emperor of Germany's Palace. Messrs. Smith & Sons' business was founded more than a century ago. The present owners represent the fourth generation of the family.

The Railway Conference.—We understand that the President of the Board of Trade has appointed Mr. E. W. Berry, fruit-grower, Faversham, to serve on the Sub-committee of the Railway Conference which is considering the question of rates and other matters connected with transport.

Royal Meteorological Society.—An ordinary meeting will be held at the Institution of Civil Engineers, Great George Street, Westminster, S.W., on Wednesday, April 15, at 7.30 p.m. Papers to be read: (1) "Report on the Phenological Observations for 1907," by Mr. Edward Mawley; (2) "The Anticyclonic Belt of the Southern Hemisphere," by Colonel H. E. Rawson, C.B., R.E., F.R.Met.Soc.

The Imperial Russian Horticultural Society.—On February 21 of the present year a festival in commemoration of the fiftieth year of its existence was held by this society in St. Petersburg, numerous distinguished guests, honorary members, and members being present. Among the honorary members are H. Hermann Holzer, and Court Gardener Katzer, both of whom were present at the foundation of the society 50 years ago. The latter gentleman was not present at the Jubilee festival, as, owing to his great age, he was unable to journey from Zarskojo-Selo. To mark the fiftieth year of the society's existence, it is intended to hold an exclusively Russian Horticultural Exhibition in St. Petersburg, from May 9 to 22 of the present year.

Insurance against Damage by Hailstorms.—The 13th annual general meeting of the Nurserymen, Market Gardeners' and General Hailstorm Insurance Corporation, Ltd., was held at 41 and 42, King Street, Covent Garden, on Friday, 3rd inst. The accounts showed an increase in the year, both as regards premium income and interest, as the year had been peculiarly free from hailstorms. During the 13 years of the society's existence, the premium income has increased from £681 1s. 9d. to £2,476 13s. 10d. A dividend of 7½ per cent. and a bonus of 2½ per cent. was declared, and £1,500 added to the reserve fund, which now stands at £13,500. The invested funds amount to £23,969 0s. 7d. The area of glass now insured amounts to more than 35,500,000 square feet.

Fig. 102.—"Leura," the residence of T. H. Payne, Esq., at Toorak, near Melbourne, Australia.
(See also Supplementary Illustration.)

Midland Daffodil Society.—This society's exhibition will be held, as usual, in the Botanical Gardens, at Edgbaston, near Birmingham, on April 23 and 24. The prize money amounts to about £175, and classes are provided for flowers other than Narcissi, so that a good show may be expected. The most important class is one for a collection of 50 varieties of Daffodils, excluding those of the Polyanthus section. In addition to quality of the flowers, the judges will be influenced in their decision by correct nomenclature and taste in arrangement. The "Bourne" Memorial Challenge Cup is offered for the best group of 12 distinct varieties of Daffodils raised by the exhibitor. The schedule contains 53 classes, and these include many for amateurs only. Several have been added for the newer varieties of Daffodils, in order to encourage the raising of seedlings. The hon. secretaries are Rev. Joseph Jacob, M.A., Whitewell Rectory, Whitchurch, Salop, and Mr. Herbert Smith, 22, Tenby Street North, Birmingham.

PRESENTATION AT VICTORIA PARK.—Mr. R. J. GILES, late foreman of this park, has been appointed superintendent of Myatts Fields, Camberwell, and on March 30 his late fellow-employés presented him with a marble clock. Mr. J. W. MOORMAN, superintendent, in making the presentation, referred to the abilities of Mr. GILES and to the good feeling that had existed between him and the staff and stated that he himself had his first management under the London County Council at Myatts Fields.

LEAF-FALL AND TEMPERATURE.—The effect of temperature in connection with leaf-fall is well shown by an illustration which appeared in *Die Gartenwelt* some weeks ago. The illustration was from a photograph of a number of Pavia trees planted along a road-side, and was taken in November last. The trees had all completely lost their leaves, except those branches which were near the street lamps, and these still retained their foliage. The trees formed a striking object-lesson on the effect of night temperatures in accelerating leaf-fall, for, of course, during the daytime the lamps were not alight. The converse is seen when a branch of an outside vine is trained into a greenhouse or vinery—as is well known. The leaves appear on such a branch long before they unfold in the parts growing in the open air.

PLANTS AND COAST EROSION.—The problem of coast erosion is one that appeals to all inhabitants of a sandy or muddy littoral. An article by Dr. STAPF has recently appeared in the *Gardeners' Chronicle* (January 18, p. 33) dealing with this matter, and explaining the use of species of Spartina in binding and consolidating the foreshore. We read in the *Journal of the Board of Agriculture of British Guiana*, that another species, Spartina braziliensis, has been used for preventing erosion on certain littoral estates in that country with great success. The grass is planted in rows 6 feet apart and 2 feet in the rows. The plants flourish and soon meet, forming dense patches, which root deeply and firmly. Even if they are covered by mud washed over them, they soon make their way through it again. On the estate in question, as soon as the grass is firmly established, Mangrove seedlings are planted in it, and ultimately form dense thickets that effectually prevent further erosion.

PICTURE EXHIBITION (see also p. 237).—Mr. HERBERT OLIVIER'S exhibition at the Grafton Galleries, which will be open until April 14, is well worth a visit. The collection comprises some striking portraits, charming pictures of the picturesque gardens at Kew, and some sketches of various places in Italy. The collection of portraits of princes of Central India is a most interesting one, the quiet dignity of the faces contrasting so quaintly with the masses of marvellous gems, almost barbaric in their splendour. The collection has been painted for the Daly College in India, where they will be hung in the Great Hall. The pictures of Kew Gardens, which will form the illustration to a book that has been compiled by some of the staff, contain some delightful sketches. It is hard among so many attractive pictures to pick out any as being most attractive, but No. 98, "Bluebells," the subject of which is wild Hyacinths lit up by sunlight filtering through branches of trees, was certainly one of the gems of the collection. Mr. OLIVIER also exhibits some sketches and pictures of various parts of Italy. We delighted in No. 129, an Ilex, near Netuno, which is beautiful in its breadth and simplicity, and, we may add, deserves a better position than has been allotted to it in the exhibition.

INTERNATIONAL SHOW AT NANCY.—Horticulture is to be fully represented at the International Exhibition of the East of France, to be held at Nancy from May to October in 1909. The horticultural section will comprise a show which will remain on view during the whole period of the exhibition, and also a number of separate shows to be held during the months of May—September. Those who desire to exhibit in the permanent section are requested to apply before July 1st, 1908, if they require to utilise the space this year, and before November 1 if they desire to commence operations next year. They are asked to state the nature of the exhibits they propose to offer. Those desiring to exhibit at the ordinary shows, of which four or five will be held, each lasting four days, are requested to apply to the Direction Generale, Nancy, six weeks before the show at which they wish to exhibit.

THE FELLOW'S "IVORY."—At fig. 103 we have illustrated a "tally," which was formerly employed by the Royal Horticultural Society in place of the tickets which are now issued annually to the Fellows. This "tally" was recently unearthed in the kitchen garden at Brookfield, near Arundel, where it has probably been buried for nearly half a century. It is inscribed with the name of JOHN HALBY, and in order to determine the period at which this gentleman was a Fellow of the Horticultural Society we communicated with the Rev. W. WILKS, who has courteously supplied us with the information that, on reference to

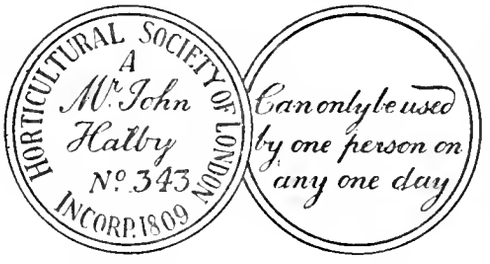

FIG. 103.—"TALLY" ISSUED BY THE HORTICULTURAL SOCIETY OF LONDON.

the society's books, he found that Mr. HALBY ceased to be a Fellow in 1863, therefore this particular "tally" must have been issued earlier than that year, and probably about the year 1853. It was made of ivory, and used to pass by the name of "The Fellow's Ivory." For the opportunity of figuring this interesting relic of the Royal Horticultural Society, we are indebted to Mr. F. KING, the gardener at Brookfield, who sent us the "ivory" for the purpose. Mr. KING states that "the present owner of Brookfield, EDW. CARLTON HOLMES, Esq., is in his 90th year, and his father resided at Brookfield before him. The gardeners at that residence can be traced back for nearly a century, one, TAPNER by name, being there for more than 50 years, but no one of the name of HALBY has been traced."

ORCHID SALE AT GHENT.—The sale of the collection of Orchids formed by the late Marquis DE WAVRIN is announced to take place at Ghent during the Ghent Quinquennial Show week, the dates being fixed for Monday, April 27, Tuesday, 28, and Wednesday, 29, at the Salle des Ventes. The collection is one of the richest and most varied in Belgium, and includes a selection of fine white Cattleyas, which is one of the most complete in existence; a remarkable display of these flowers was made from this collection at the last Ghent Quinquennial Exhibition. Varieties of the showy, large-flowered Cattleyas, Lælias, and Lælio-Cattleyas were special favourites with the late marquis, who also raised many good hybrids.

VIOLETS IN FRAMES.—On p. 217 in the last issue we stated that Violets of excellent quality had been sent us by Mr. STOKES, of Cokethorpe Park Gardens, Witney, Oxon, who has since obligingly furnished us with the following particulars of his method of cultivating these flowers:—"At the end of April a fresh start is made for the following season's blooming. The old plants are taken from the ground and pulled apart, the strongest and best rooted crowns being selected for the new stock, and all old and central crowns discarded. The crowns are planted 12 inches apart each way in their summer quarters, choosing a site facing to the north-west, the soil having been previously well dug and enriched with a moderate dressing of rotted stable manure. After planting, the young plants receive a copious watering, and for some days they are shaded during bright sunshine. Attention is given the plants throughout the summer, the work of hoeing, weeding, watering and the removal of useless runners being carefully performed. Should red spider attack the plants, they are syringed occasionally with soot water, the best time for the operation being late in the afternoon. Towards the end of September the plants are lifted and placed in cold frames facing to the south. These frames are used for the culture of Cucumbers, and all that is necessary is to place a few inches of fresh soil in them before planting the Violets. The plants are well pressed in the soil, and afterwards watered. The lights are kept closed for a few days, but after the plants are established an abundance of ventilation is given on every favourable opportunity throughout the winter. Care is taken to exclude frost and fog. Very little water is given during short, dull days in winter, and in this matter the exercise of discretion is necessary."

POTATO SCAB AND LEGISLATION.—A deputation of the National Fruit Growers' Federation have attended at the Board of Agriculture on the subject of the "black scab" disease of Potatos. The Federation desires that this pest be made a notifiable disease under the Destructive Insects and Pests Act, 1907, with the object of enabling the Board of Agriculture to ascertain at once the exact areas at present affected. Also that where the disease is known to exist on any farm or holding, it shall be illegal for the grower to sell any Potatos until the same shall have been examined by an inspector from the Board of Agriculture, or other duly qualified person; and that all tubers found to be diseased by black scab shall be destroyed, the grower to be compensated for the same up to half their value, such compensation to be paid from the Treasury funds. Further that within a period of seven years every grower who plants Potatos in ground where the disease has previously existed shall be required, before offering the crop for sale, or allowing it to be removed, to possess a certificate from the Board of Agriculture certifying that the same is free from the disease. It is desired that no restrictions be placed upon the growing of Mangel or Beetroot on land contaminated with the black scab disease of Potatos. In view of certain statements that have been made, the Board of Agriculture is requested to investigate as to whether the disease is being introduced into this country by means of imported tubers. As a result of the interview, the Board of Agriculture has invited a deputation of Potato growers and other persons interested in the matter to attend the Board's offices at an early date, and discuss the question of the measures to be taken. Further particulars may be obtained from the Secretary to the National Fruit Growers' Federation, Royal Horticultural Hall, Vincent Square, Westminster.

BRITISH GARDENERS' ASSOCIATION.—We are informed that a public meeting will be held at the Eccles Rooms, Station Road, Blackburn, on Wednesday, April 15, at 7.30 p.m., when a delegate from the Executive Council will deliver an address, with a view to forming a new branch of the Association.

FORESTRY IN SCOTLAND.—Considerable interest is being aroused in arboricultural circles in Scotland over the Royal Scottish Arboricultural Society's forthcoming Forestry Exhibition at Aberdeen in connection with the Highland and Agricultural Society's show from July 21 to 24. The committee has issued a schedule inviting members and others interested to offer exhibits for approval. The exhibits required are:—Specimens illustrating the rate of growth of trees, together with a statement of their age and crop per acre; specimens of any abnormal growth of trees; different kinds of wood; pitwood and railway timber; examples of turf or soil, illustrating the advantages of pasturing woodland or waste land by stock previous to planting; plants, trees, and timber damaged by storms, frosts, insects, animals, birds or other causes, and specimens of insects, animals, birds, or fungi which caused the damage; plants with rootlets, showing the results of various methods of transplanting; tools and implements—home and foreign—used in various operations connected with forestry, with their prices; working plans, maps, and diagrams, giving details of management; seeds of various kinds of forest trees, with description of methods of collection and extraction: cones and foliage of different kinds of Conifers; pictures and photographs connected with forestry; general forest literature, and anything else of interest relating to forestry. The entries must reach the hon. secretary, Mr. ROBERT SCOTT, solicitor, 75, Union Street, Aberdeen, not later than May 30.

Publications Received.—*The First Book of Farming*, by Charles L. Goodrich. Published by Archibald Constable & Co.—*Quarterly Journal of Forestry for April.* Published by Simpkin, Marshall, Kent & Co.—*Colour in the Flower Garden*, by Gertrude Jekyll. Published by George Newnes.—*Essex Education Committee—Higher Education Report for 1907. Some new cases of Mendelian inheritance (with four figures)*, by George Harrison Shull.—*Importance of the Mutation Theory in Practical Breeding*, by George Harrison Shull. Both reprinted from Proceedings American Breeders' Association.—*The Complete Farmer: Soils, their Nature, and Treatment*, by Primrose McConnell. Published by Cassell & Co., Ltd.—*Cassell's A B C of Gardening.* An illustrated encyclopædia of practical horticulture, by Walter P. Wright. Published by Cassell & Co., Ltd.—*The Horticultural College, Swanley, Kent.* Syllabus of Work, January, 1908.—*A Plant Book for Schools*, by Otto V. Darbishire. Published by Adam and Charles Black.—*Contributions to the Flora of British New Guinea*, by F. Manson Bailey, F.L.S., Colonial Botanist. Extracted from the *Queensland Agricultural Journal*, vol xix., part 5, November, 1907.—*The Germination of Vegetable Seeds*, by Edgar Brown, Botanist in charge of Seed Laboratory, and Willard L. Goss, Assistant, Seed Laboratory, being a pamphlet issued March 7, 1908, by the United States Department of Agriculture.—*The Botanical History and Classification of Alfalfa*, by Carl S. Scofield, Agriculturist in charge of Western Agricultural Extension Investigations, being a pamphlet issued March 14, 1908, by the United States Department of Agriculture.—*Apple Leaf-spot caused by Sphaeropsis malorum*, by W. M. Scott, Pathologist, and James B. Rorer, Assistant Pathologist, Investigations of Diseases of Fruits. Pamphlet issued March 12, 1908, by the United States Department of Agriculture.—*The Nut Weevils*, by F. H. Chittenden, Sc.D., Entomologist in charge of Breeding Experiments (Circular No. 99). Issued March 6, 1908. Reprinted from the *Year-Book of the Department of Agriculture* (American) for 1904, pp. 299-310, pls. xxviii.-xxx, text figs. 17-26.—*Market Classes and Grades of Horses and Mules* (Bulletin No. 122), by Rufus C. Obrecht, and *Variety Tests of Wheat* (Bulletin No. 121), by Albert N. Hume, O. D. Center, and Leonard Hegnauer, both from the University of Illinois Agricultural Experiment Station.

NOTICES OF BOOKS.

* THE ART OF LANDSCAPE GARDENING.

THIS book is a reprint of some of the writings of Humphry Repton, who practised landscape gardening in England about a hundred years ago. His writings collectively form a series of works on the principles of landscape gardening, such as had never previously been attempted, and never since have they been equalled, notwithstanding the abundant literature on the subject.

He wrote mainly about the principles of what may be termed broad landscape gardening as applied to parks and areas of great extent, and distinct from the "landscape gardening" of present-day writers, who confine themselves to the mere laying out of a garden and the immediate surroundings of a residence.

This reprint, we are told in the preface to the book before us, is intended to commence "a series of classics in landscape architecture which has been undertaken at the suggestion and with the co-operation of the American Society of Landscape Architects," and is edited by John Nolen, A.M., a member of the American Society of Landscape Architects.

It was a wise choice of the society to commence the projected series with a reprint of Repton's *Theory and Practice of Landscape Gardening*, published first in 1803, and his *Sketches and Hints on Landscape Gardening*, published in 1794, as these are two of his best works, and together with his *Fragments of the Theory of the Art of Landscape Gardening*, published in 1816, and *An Inquiry into the Changes of Taste in Landscape Gardening*, published in 1806, constitute a classic of the art.

Since Repton no writer has dealt so thoroughly with the purely theoretical aspect of the subject in such an original way, though he has often been copied, and even during his day he speaks of his many imitators in practice.

This American reprint is the more welcome as Repton's books are more or less rare, for though Loudon published in 1838 a reprint of the four works mentioned, even this work is only to be met with occasionally among second-hand books. Now this compact volume brings two of the works within the range of everyone.

These two, the *Theory and Practice* and *Sketches and Hints*, provide intellectual food for students of the subject, written in the lucid, pure English that characterised the writers of that period.

He who has no previous acquaintance with one author will doubtless contrast the difference between Repton's discourses on the art and the recent treatises on landscape gardening. For the latter, taken generally, deal only with those narrower details of garden design, which for Repton merely formed the embroidery of the principles he did his utmost to expound. Repton mainly dealt with square miles, while modern writers deal with rods and acres.

We can now appreciate the work of such men as Repton, for we see around us the many beautiful gardens and parks with the mature growth of a century, and which are the glory of rural England. We have only to reflect upon the beauties of such places as Cobham, Welbeck, Thoresby, Holkham, Glevering, and many others that Repton transformed, to recognise in him an artist of rare ability and genius. We appreciate now the mind of the man who so accurately anticipated the future effect of his work, for he well knew, as all do who work in the same direction, that it is only after two or three generations that the mature effect of garden and park scenery can be seen.

Indeed, Repton says in one of his works that the landscape gardener is at a great disadvantage in the practice of his art as compared with the architect who can show on plans the full effects of his buildings which in the course of a few months or years can be seen in reality, whereas the landscape gardener obviously can only imagine the picture he aims at producing after a long lapse of time when the tree growth has matured.

But, he goes on to say, that as soon as the architect has completed his work the fabric begins to decay, whereas from the completion of the planter's work every year marks a stage towards the realisation of his anticipated landscape scene.

In the study of Repton's writings one must necessarily make allowance for the difference between the conditions existing in his day, which may be termed the dawn of English landscape gardening, and those of the present time, for though the principles of the art always remain the same, there has been in the long interval a great change in what may be termed "fashion" or "taste."

In those early days the prevailing fashion was the formation of the grandiose style of residence surrounded by deer parks of great extent. The creation of these often necessitated the abolition of arable land, though this was the chief source of income. In these democratic days it is quite unlikely that the fashion will revive in such a small country as these islands, though in such a continent as America, with illimitable areas, the lordly ideas of Repton can be carried out in park and garden landscape, as indeed they are. In Repton's days what we now call ornamental gardening did not enter largely into the scheme of landscape gardening, for beyond the walled enclosures for fruit and vegetable growing, which were often of great extent, there was little of what we call the garden around the house. The residences were surrounded by parks with magnificent tree growth, and deer and cattle grazed under the windows of the house. Fashion and other circumstances have changed all this. Now it is a rare occurrence to hear of a large park being made, but the formation of gardens is more and more on the increase. Therefore those who take up Repton and think they will find in him a guide for the designing and making of gardens will be disappointed, for he ignored detail, particularly as regards the material, such as trees, shrubs, and plants, which form the essence of beautiful gardening.

Repton dealt only with broad principles, and on these he always wrote with a lofty ideal. The choosing of sites for houses was a matter that concerned him greatly, and he gives his reasons for the selection of particular sites. He always dealt with every place on its merits or peculiar circumstances of the situation and surrounding country, and these conditions obtain now as then except that now residences can be placed on hills owing to modern appliances for raising water.

The planning and laying out of roads, entrance lodges, and the formation of artificial lakes were matters of great concern with Repton. His lines of roads as exemplified in his plans were always sensible and graceful, though we should in many cases prefer the stately straight avenues of trees which he in some cases destroyed, in order to make his curved lines. His treatment of artificial water was always artistic, that is the artificiality was not apparent, and there are many park lakes and streams in this country made by him which one can scarcely realise to be artificial until the dam is seen.

But it was in the bold schemes of park and woodland planting that Repton appears to have excelled, and we enjoy to-day the result of his bold conception in the grand woodland scenes, as at Beaudesert, Bayham, Thoresby, Holkham, a few among many others of his works that have ripened into maturity during the past century. These magnificent examples of tree landscape gardening tend to elevate the art in

* *The Art of Landscape Gardening*, by Humphry Repton. Edited by John Nolen, A.M. Boston and New York: Houghton, Mifflin & Co. London: Archibald Constable & Co., Ltd.

the minds of lovers of nature, and they form a strong contrast to the puny works of landscape gardening about so many houses at the present day.

Enough has been said of the book to commend it to the notice of everyone interested in the subject, and especially to those young people who are studying the matter, who will find it helpful in assisting them to grasp the subtleties of the art, though it may never make them landscape gardeners unless they have a natural gift in this direction, for, as with all successful art workers, they are born not made.

The book is reproduced in the commendable style one expects from American printers. It is well illustrated, many being reproductions from Repton's original works, and there are photograph reproductions of views of his work as seen at the present day, such as Thoresby and Clumber. There are also illustrations which show an ingenious device of sliding sheets, how a place appeared before he began to work upon it and how it would appear after it had been "Reptonised." He originated this peculiar method in his original *Red Books*, which contained his reports on important places, illustrated by original plans and drawings.

Repton originated the term "landscape gardener." Before his time workers in this direction were termed "improvers" or "planners." Though the term is now general in this country, and we are not ashamed of it, our American friends as a rule ignore it and call themselves "landscape architects," which is only a degree more appropriate than another of their terms, "landscape engineer," which is too atrocious a term to ever get a foothold in this country, however desirous one might be to find a substitute for the term landscape gardener. *W. Goldring.*

LAW NOTE.

TRADE NAME DISPUTE.

MESSRS. Alexander Dickson and Sons, Ltd., carrying on business in Newtownards, Belfast, Dublin, Blackrock, and also in Hertfordshire, have recently sued for an injunction in the Irish Chancery Division restraining Mr. Alexander Dickson and his two sons, who are in business as seed merchants in Parliament Street, Dublin, under the name of the Ashbourne Agricultural Company, and as Rose-growers and nurserymen at Woodlawn, Dundrum, under the name of Alexander Dickson and Sons, from selling Roses or seeds not grown or propagated by the plaintiff company as Dickson's Roses or Dickson's seeds, and from carrying on the business of nurserymen and seedsmen under the style of Alexander Dickson and Sons, or any style in which the name Dickson appears, without taking reasonable precautions to clearly distinguish the business carried on by the defendants from that carried on by the plaintiff company. The plaintiffs alleged that their Roses have obtained a world-wide reputation for excellence, and that Roses stated to be Dickson's would be understood in the trade and by purchasers as the plaintiff company's Roses. They further charged that Mr. Alexander Dickson, the principal defendant, who, until February, 1907, carried on business in Parliament Street as the Ashbourne Company, had opened a nursery at Dundrum under the name of Alexander Dickson and Sons, with the object of taking advantage of the reputation of the plaintiff company for Roses and seeds. The defendants repudiated all these allegations in their defence, and denied that there is any foundation for them. Leave had been given to administer a series of interrogatories to the defendants as to the origin of the name under which they were trading, the date on which they adopted that trade description, and other queries relating to the nursery business.

The Master of the Rolls held that certain of the answers were uncandid and not sufficiently full; and, adjourning the case, made an order that the defendants should disclose the facts asked for by the plaintiffs.

THE GHENT QUINQUENNIAL.

ORIGIN AND HISTORY OF THE ROYAL AGRICULTURAL AND BOTANICAL SOCIETY OF GHENT.

ABOUT 1622 the Bishop of Trieste, whose taste for art and flowers is famous, formed a fraternity of gardeners under the patronage of St. Amand and St. Dorothy. The fraternity had its chapel in the Church of St. Michael, where on the Saints' days the altars of St. Amand (1) and St. Dorothy (2) were decorated at the cost and by the care of the fraternity.

Besides this, there was also at Ghent a fraternity of amateurs whose altar was in the Abbey Church of St. Peter, and was founded in 1669 by the Abbot Reyntkens, author of a treatise on gardening which was published in 1675.

These two fraternities suffered the fate of all the others, and were suppressed by the decree of August 18, 1792. But the taste for plants and flowers grew apace with the public prosperity. The number of gardeners increased, and besides those who were employed by the large landed proprietors and wealthy amateurs, little by little the professional gardener, half florist and half market-gardener, set up in business round the town. It was chiefly along the Coupure where their nurseries were to be found. Even after the alterations in this part of the town the nurseries remained. The old establishment of Linden's has only of recent years been turned into building land, and on its site a new street made called the Rue Liévin De Winne. On the right bank of the Canal de la Coupure, behind the Salon Napoleon, there still exists a large space of land occupied by Mr. B. Spae's greenhouses. At the beginning of the 19th century, on the right bank, at the place where the Passage de la Coupure joins the paved roadway, was a famous inn or public-house bearing the sign of "In Frascati." It was kept by a gardener and his colleagues, of whom many lived in the neighbourhood, or else had ground there and were the principal customers. Amateurs also frequented the place to talk about their subjects of common interest on the principle of the old proverb "Birds of a feather flock together."

About this time England, thanks to the advantages she enjoyed by the possession of her colonies and the development of her marine, had made great progress in horticulture. New plants were introduced there without cessation, the cultural methods were greatly improved. The importance of this branch of industry was so considerable in that country at the beginning of the 19th century that the English nurserymen had catalogues of their goods printed and circulated all over the Continent.

Gardeners and amateurs had on several occasions crossed the Channel to view the wonders of English cultivation and bring back from Great Britain the horticultural novelties. We can easily imagine with what curiosity the customers at "Frascati" awaited the return of these fortunate and enterprising professional and amateur gardeners, and what a full house there was on the evening of their arrival.

It was at one of these gatherings that the Royal Agricultural and Botanical Society of Ghent was formed. On October 10, 1808, Frans van Cassel, gardener and botanist, related to his friends and colleagues what he had seen in England, whereupon it was resolved to form a society for the purpose of holding flower shows and promoting the love and culture of plants in Ghent. The idea was received with enthusiasm, and forthwith the lawyer, Mr. L. Lebègue, judge of the Court of First Instance and an amateur of some distinction, undertook to draw up the rules. On October 28, 1808, the proposed rules were submitted to the Mayor, M. Pycke, for approval according to law. As a proof of the way in which the taste for horticulture had spread at that time among the people, we give below the names and callings of 47 townspeople who signed the request addressed to the Mayor.

List of 47 founders of the society, viz., Messrs. C. Reylof, private gentleman; P. A. Verschaffelt, gardener; F. Spae, ditto; L. Verleeuwen, ditto; L. de Coninck, ditto; J. de Herdt, ditto; J. Alberdienst, ditto; L. De Bieve, architect; J. B. Carbonelle, plumber; J. X. Van de Woestyne, shareholder; Ch. Goethals, advocate; L. Myncke, gardener; E. Haemelinck, shareholder; J. B. Van Coppenole, surgeon; A. Houssiaux, bailiff; Van Bambeke, brewer; J. M. Verdonck, priest; Lavandan, private gardener; Versturme, private gentleman; J. Van Lokeren, doctor; A. Spiller, gardener; A. Taminiau, surgeon; J. Bonnet, engraver; P. Terveert, manufacturer; J. Sudan, private gentleman; Du Colombier, gardener; P. L. Pyn, merchant; L. Lebègue, advocate; J. M. Mussche, head gardener to the Botanic Garden; J. B. Delbecq, schoolmaster; P. Fermont, architect; J. Malpré, painter; P. de Graeve, private gentleman; J. Dubois, amateur; l'Olivier, police commissary; P. Mortier, amateur florist; B. Alexis, manufacturer; P. Van Rossem, ditto; A. Schellinck, private gentleman; C. Lanckman, gardener; J. Verleeuwen, gardener; Van Winghen, shareholder; H. Willems, gardener; P. de Cock, ditto; F. Van Cassel, ditto; J. Van der Woestyne, doctor; C. Schepens, gardener.

It will be noticed that these names belong to all classes of society. The favour with which the society was at the outset regarded is clearly shown by those who accepted office. The president, Van de Woestyne, belonged to a great Ghent family; the secretary, Lebègue, was an advocate and a judge; the treasurer, Goethals, was an advocate. In 1810 F. F. Verbeeck, the surgeon, was elected general secretary, whom we find shortly afterwards professor at the university.

The objects of the society, as well as the means to attain them, are thus set forth in the 2nd and 14th rules:—

Rule II.—The object and aim of the society are the diffusion of botanical knowledge and the cultural improvement of indigenous and exotic plants.

Rule XIV.—Every year, on the fête day of St. Dorothy, the patron saint of gardeners and botanists, a public exhibition of plants, flowers, and shrubs shall be held in one of the garden halls of "Frascati," and shall be advertised in the "Gazette de Gand" at least eight days beforehand. To render this exhibition interesting and useful every member must send to the hall at least three days in advance two pots containing plants, flowers, or shrubs of his own selection under a penalty of incurring a fine for each pot wanting, a fine of 63 centimes, or one escalin (1). Every member, however, will have the right to send more than two pots, but the number must not exceed six. The name of the exhibitor must be written on each pot to avoid disputes as to ownership. The arrangement of the pots in the showroom will be made by five stewards appointed for the purpose by the officers, and every member must accept this arrangement without protest, and he who displaces a pot to substitute his own or another shall pay a fine of one franc six centimes, or two escalins, and the pots so displaced shall be put back in their original position.

To carry out this programme, the young society held its first exhibition in its headquarters, "In Frascati," on February 6, 1809, and it obtained so great a success that in 1815 its old home became quite inadequate, and it then moved to the Rue de la Caverne to a tavern of the sign of "In de Zaal Flora," and here a special hall was constructed for the shows.

In 1818 the society, having gained the sympathy of King William, begged for the privilege of calling itself a royal society, and asked for a grant of a coat of arms. The King acceded to the request, and granted the society the title of "royal." The Herald's College registered the arms, a waterpot, a spade, a rake, and other garden tools, with the motto, *Venefficia mea, Quiriles, haec sunt.* This motto alludes to a legend bequeathed to us by the Romans. They say that in the days of ancient Rome a gardener of Latium surpassed all his competitors by the perfection of his flowers and the favour with which his products were received. The young patrician women would have no other flowers but his with which to ornament the garlands they used to offer to Venus, and the courtesans no Roses but his to crown the guests at the Bacchanalian feasts. This fortunate florist's colleagues denounced him to the Pontifex Maximus, charging him with having relationship with the powers of darkness, who, as they alleged, taught him the

(1) A Dutch coin worth about 6d.

secrets of cultivation. A trial for witchcraft was the result, probably one of the first, and when he appeared before the court, the good man, to the astonishment of the judges, simply produced the tools of his craft, and the only defence he could make was to utter the words, "My sorcery, my lords, are these."

The continued and increasing success of the shows necessitated another change of place, and in 1827, by resolve of the Common Council, the grand vestibule of the Town Hall was placed at the disposal of the society for its floral fêtes. The library and collections were placed in the Grande Conciergerie of the same building, and it is there that the Council of the society has since held its sittings. During the events of 1830-31 (1), the shows were not discontinued, but were held in St. George's Hall, now the Leipsic Fair, at the corner of the Rue Haut Port and the Butter Market.

In 1832 the society returned to the Town Hall, where it remained until 1836, except in 1834, when the March Show was held in the vestibule of the Palace of the University to enable it to celebrate the 25th anniversary of its existence. On this occasion the ever-increasing prosperity of the society induced the members to secure premises more in accordance with the position it had acquired. A joint stock company was constructed, having for its object the erection of a building suitable for housing the Royal Agricultural and Botanical Society and the Philharmonic Society of St. Cecilia. The town gratuitously gave up to this company the site of a mill and some unoccupied land belonging to it situated at the Coupure, close by the birthplace of the society, where it had been started in 1808.

While preserving its old title, it took, in addition, the name of Casino. The building was executed on the plans of the Architect Roelandt by the builder Kerfyser. In 1839 the Philharmonic Society of St. Cecilia left the Casino to go to premises at Spiegelhove; this change was fatal, and the society ceased to exist in 1840.

The Casino Company scored success after success, and in 1866 a further enlargement was considered necessary. The garden, of semi-circular form, where the open-air concerts were given, was covered in, and became the great winter garden which now exists. This glass structure was executed, so far as the ironwork is concerned, by Mr. Carels, Senr., from the plans of Mr. Adolphe Pauli, professor at the University.

Now the ever-growing requirements and the continued success of the shows have necessitated a new transformation in view of the celebration of the centenary fêtes. These later works, carried out in 1906, have been undertaken by Messrs. Myncke Bros., under the supervision of Mr. De Waele, architect.

THE APPROACHING EXHIBITION.

The International Horticultural Exhibition, which will mark the hundredth anniversary of the foundation of the Society, will be held in the Casino from April 25 to May 3. The annexe of the exhibition has been erected in the Casino gardens by Mr. Schauvliege, from the plans of Mr. de Waele, the architect. This building, of gigantic proportions, covers about 2½ acres of ground. Its elegant facade faces the existing imposing building, and produces the finest effect, set off with mouldings and allegorical paintings. In the immense greenhouse, the design of the plan is the work of Mr. Fred Burvenich, Senr., the distinguished professor of horticulture, who, with Van Halle, Ed. Pynaert, and Rodigas, made up the rare "four-leaved Clover," as they were familiarly called in the horticultural world.

Mr. Burvenich has endeavoured to give to the exhibition hall a powerful, far-stretching perspective, being careful to arrange paths wide enough to allow thousands of visitors to pass round. At the far end of the annexe is an immense painted panel representing an English garden, the work of the artists Bylebier and Tolffaert, which will complete the panoramic illusion.

On the Coupure side the middle of the hall will be occupied by the exhibition of 50 plants shown a century ago at the little inn "Frascati." The spectators, who will be supposed to be in the smoking-room where the first "Salon de Flore" was arranged, will look out on the garden of the inn, with its characteristic arbours called "gloriettes," surrounded by the modest yet typical landscape of Meulenberg. This optical illusion is obtained also by the assistance of a painting executed by the same artists.

Finally, a view depicting the severe and impressive landscape of the Cape will serve as a background to the new plants imported in such large numbers from the south of Africa.

The efforts of Mr. Heursel-Demeester, the devoted curator of the Society's collections, to bring together the 49 or 50 plants shown in 1809 have not entirely succeeded, for there is one wanting, the Rosea portlandia; but the patient collector does not yet despair, and is in communication with the leading English and Austrian botanists.

The designing of the plan in the large winter garden will be the work of Mr. Charles Pynaert.

The handsome ballroom will be the Orchid palace. From the flight of steps to this room will be viewed a French garden, with its symmetrical design, which, in the open air, will connect the two buildings.

More than 300 persons belonging to the élite of the European horticultural world have been invited as members of the jury. Some of these will celebrate at the same time as the centenary of the Society the fiftieth anniversary of their first visit to the City of Flora. In the traditional country of the Tulip not a single juror invited has refused the honorary distinction, and from the banks of the Amstel is announced the despatch of plants for exhibition by special motor boats.

A number of nurserymen in and around Ghent have given foreign exhibitors the use of their greenhouses. They are pushing forward plants that are too delicate to undergo the perils of a long journey just previous to the opening of the show.

(1) The revolution by which Belgium was separated from Holland.

NOTES FROM THE "FRENCH" GARDEN.

Lettuces and Melons are now requiring constant attention. Carrots are growing well. We have had to give them a thorough watering, and it will be necessary for us to give them further waterings from time to time, it being important that they should continue to be ahead of the Cauliflowers that have been planted amongst them. The lights are left open day and night at present, in order to keep the growth sturdy.

The Cabbage Lettuces planted with the Cos Lettuces under the cloches at the end of February are being sent to market during the present week. They have succeeded well, as have the Cos Lettuces, which are filling other cloches. The somewhat cold weather in March was favourable to the Lettuces, for it prevented them growing tall and encouraged them to make hearts. Out of doors we have planted Cos Lettuces and Cauliflowers raised in the autumn. They have been planted at 2 feet apart each way.

At the end of January we planted a variety of Cabbage Lettuce known as "Passion." The seeds were sown and the seedlings pricked off just as was done in the case of the Black Gott Cabbage Lettuce and the Paris Green Cos Lettuce. They were planted in frames, and 25 plants were put under each light. We do not prepare hot beds for the "Passion" Lettuce, this variety being particularly hardy. During last week five Cauliflowers were planted amongst these Lettuces under each light. Presently we shall take away the frames and lights, and these will be used for the second batch of Melons. The first batch of Melons, planted rather more than a fortnight ago, are doing well. We had to fill the paths between the frames with fermenting manure, as the winds are very cold, and it is necessary to keep the temperature of the beds as equable as possible. Air is admitted to the Melons every day; even if it is only possible to do this for half an hour it effects a complete change of atmosphere, and the plants become less likely to attacks from the stem disease that so often destroys Melon plants.

Seeds of Celery were sown on a hot bed during last week. We grow the two varieties, Chemin and Green Celery, the latter variety to form the main crop. The Celery will follow the Cauliflowers which were planted recently among the Carrots, after the clearance of the Cauliflowers in July. *P. Aquatias, Mayland, Essex.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

Elementary School Gardens.—The letter of *A. D.* (see p. 219) on the subject of school gardens contains a reference to the value of gardening work for girls as well as boys. Gardens in connection with elementary and secondary schools for girls is an accomplished fact in Ireland. A number of these gardens have been in existence for several years, the course of instruction including lessons on flower, fruit, and vegetable culture, and the girl students are no less keen than their more sturdy brothers. As a rule, a plot is allotted to each of the pupils, and all the work of planting, sowing, and cultivating the various crops is carried out by them just as it is by boys of similar age in their gardens. Certainly anything the girls lack in strength they make up in enthusiasm, and at present no girls' school which has commenced this work has abandoned it. All this is done without any grant, except the occasional services of an instructor, and as none of the schools distribute the produce, other than surplus plants, it is evident that the subject only needs to be properly taught to at once become as popular among the girls' schools as among the boys'. In this country, at any rate, the value of a knowledge of gardening to the girls as well as to the boys can hardly be over-estimated, as almost every cottage has some ground attached to it which might be cropped with fruit and vegetables, and all but the heaviest of the work carried out by the wife and family of the cottager. *L. J. Humphrey, Dublin.*

The Sweet-scented Dahlia.—I think the interesting new plant mentioned in a paragraph on p. 218 of your current issue must be Dahlia coronata, offered for distribution in May at the price of two francs a plant by Monsieur Georges Bruant, of Poitiers, Vienne, France, as his description of it in his new catalogue corresponds in every way with what you say about it. I send this information in case any of your other readers may wish to acquire so desirable a new plant, as I hope to do myself as soon as it is sent out. *W. E. Gumbleton.*

Pictures of Kew (see also p. 234).—There are on view at the Grafton Galleries 184 pictures by Mr. Olivier, including a number of studies in the Royal Botanic Gardens, Kew; and in some Italian gardens and landscapes; likewise, 24 pictures of Indian chiefs. The paintings of Kew Gardens include a view of the Azalea garden, representing the east side, and having beds of these brilliant-flowering plants of the hardy species in the distance; with a large tree and ample greensward in the foreground. Another depicts a Lily pond, with the Nymphæas in flower, and trees around it. There is also a brilliant, finely-painted mass of Lilium speciosum; adjoining this picture is a view in the Rhododendron Dell, looking south and showing the plants covered with blooms. No. 11 is a view of a field of Opium Poppies—P. somniferum with flowers of various tints. A picture of the lake at Kew, with Water Lilies of various colours planted near the bank, is a well-chosen subject, and the chief feature—the Lilies—are suitably balanced in the picture by arboreal vegetation. Near this is a picture of Cypripedium insigne Chantonii, very faithfully drawn and coloured. There is another view of the lake in autumn or early spring, the slight haziness of the season being delicately depicted. In the middle gallery is a pretty picture of Horse Chestnuts, with Bluebells beneath them, and the Queen's Cottage with masses of Foxgloves in the foreground—a semi-wild type of gardening. The picture of a bank of Rambler Roses of various tints invites imitation. There is another view of the Rhododendron Dell, this time looking north. No. 81 shows the Lily basin in one of the glasshouses at Kew, with a large plant of Papyrus in the background, and white Water Lilies at the front. Pomegranates in flower show what beautiful shrubs these are in the milder parts of the country. The colours of the blossoms are very various and pleasing. A long gallery is devoted chiefly to views in Italian gardens and landscapes, with the inevitable "Stone" Pines as single trees and groups. Roses in great profusion of bloom are exhibited in a picture entitled "Banksia Roses." The Nerium Olean-

der, as it grows in Italy, is shown as good-sized trees with round crowns and smooth, grey-barked boles. A picture in this section exhibits the curious effects of grafting Willows on tall stems of the Lombardy Poplar, the bright-yellow shoots of the Willow employed having a weird appearance in the winter months. *F. M.*

MEALY BUG ON VINES.—*W. P. R.* will kill the tender young leaves of his vines, as well as the mealy bug, if he uses the hydrocyanic acid gas in sufficient strength to destroy the bugs. He had better continue the paraffin, or methylated spirit, process until the foliage gets hardened, and then try the cyanide of potassium. I have had the sub-laterals slightly scorched in July when using 1 ounce per 1,000 cubic feet, and I believe a smaller quantity than this will not have the desired effect. I think the best time to effect a cure by the above method would be as soon as the vines could be cleaned in spring, repeating the cyaniding weekly for three weeks. The house must be as dry as possible, and the temperature low, at the time of the operation. *A. S.*

———The employment of hydrocyanic acid as an insecticide when vines are bursting into leaf is not to be commended, because if the poison is used strong enough to destroy mealy bug, it will also injure the foliage. As a specific for this pest, *R. P.* should try warm water, applying it carefully by means either of a syringe or of a "Four Oaks" spray syringe, which is to be preferred. If the vineries have been kept close and damp, the foliage will be very tender and must not receive the water so hot as in the case of vines subjected to less heat and moisture. Water at 150° will be safe, and if the water is previously boiled it will not leave any deposit on the leaves and bunches, excepting perhaps an almost indiscernible spot on the lower tips of some of the berries. The syringing must be continued at intervals, and the house vaporised with the cyanide once or twice during the autumn. *R. P. B.*

———My experience is, that the destruction of mealy bug on vines, Peach trees, and Figs is not a difficult matter provided the house is vaporised with sodium cyanide. The best season to commence cyaniding is the early autumn, for then the foliage is thoroughly matured and dry. After a few further experiments have been carried out to determine exactly the proper quantity of the gas that can be used with safety on greenhouse plants, we shall be in possession of a cheap and efficient method of ridding the plant houses of mealy bug, red spider, thrips, and all other insect pests. It is advisable to cyanide the houses two or three times at intervals of a fortnight, as it is impossible to destroy the eggs. There is in commerce a safety cyaniding machine, which was illustrated in the *Gardeners' Chronicle*, March 31, 1906, p. 203, and this I recommend *W. P. R.* to procure. The maker gives all directions, including the quantities of the cyanide required per thousand cubic feet of space. It is important that very great care is used when handling the poison, as sodium cyanide dissolves very quickly when placed in the receptacles. The gas will exhaust itself in an hour or less, after which the house must be opened from the outside, but it is safe to enter the structure after the ventilators have been opened for about half an hour. The vines here were badly infested with mealy bug, and, like *W. P. R.*, we used many so-called remedies, but none was satisfactory until we used sodium cyanide. A little methylated spirit or diluted XL-All Insecticide should be kept at hand in a bottle with a brush for the purpose of destroying any stray bugs that may hatch after the cyaniding has been performed. After cyaniding has been practised for one or two seasons, mealy bug will be entirely extirpated. *H. King, Sketchley Hall Gardens, Hinckley.*

——— I have used the following method of ridding vines badly infested with mealy bug with success. After the vines are pruned, strip and clean off all the loose bark and adventitious roots, cut off all snags and knots as cleanly and closely as possible. Scrape the rods, especially around the spurs, but do not injure the wood beneath. Examine the rods, and thoroughly scrape or drill out with the point of an old knife all holes and crevices. Next give the vines a good washing with a strong solution of soft soap and hot water, using a brush that is not too stiff for the purpose, a spoke brush being the best. Care must be taken not to injure the "eyes" on the spurs. Remove all peelings, scrapings, etc., and some of the surface soil. Thoroughly scrub every part of the house, including the woodwork, glass, trellis, ventilating apparatus, walls, &c., with hot water and soft soap previous to painting them with paraffin. Work the brush into any holes or crevices, joints, &c., of the woodwork that are likely to harbour the bug or their eggs, but care must be taken not to spill any of the paraffin on the vines. After having thoroughly cleansed the house, give the rods another washing with the soft soap and hot water, and then fill up any holes in the rods with painter's putty, using a small blunt knife for the purpose. Should any eggs hatch after the vines have started (which is very unlikely if the work has been carefully done), these stray bugs may be killed by either methylated spirit or paraffin applied with a brush or a piece of sponge tied to a stick. *H. W., Compton Bassett Gardens, Wilts.*

THE GENUS PHORMIUM.—In these gardens are several large plants of Phormium that have been in their present positions undisturbed for 35 years. The clumps are about six yards in circumference at their bases; the large, lance-shaped leaves are, in many instances, 8 feet long, and the plants have developed inflorescences, some of which have attained to a height of 14 feet. Three of the largest specimens are growing on sloping banks in almost pure sand, and they are given no attention. The climate here is mild and equable, the gardens being close to the sea and within the warming influence of the Gulf Stream. The soil is deficient in lime. In regard to Mr. Bartlett's theory that a poor soil conduces to the safety of trees and shrubs of doubtful hardiness, I may state that I have proved this to be true in the case of Veronica Andersonii. This plant, when grown in soil rich in humus, and consequently very moist, is damaged by a few degrees of frost, in some instances being completely destroyed, whereas in poor, stony soil the species has grown into large bushes, enduring many years, and flowering freely annually. *F. Street, The Gardens, Ardwell, Wigtownshire, N.B.*

———My experience of this species is that the plants thrive best in a marshy situation, and I should have no hesitation in planting them there, provided they were sheltered from cutting winds, which fray the tips of the leaves and render them unsightly. Here, in the West of Ireland, this species develops into fine specimens. The best, which is situated in a valley and growing in a peat bog, is about 10 feet high and 14 feet in diameter. There are hundreds of fine plants growing under similar conditions. During last winter there occurred as much as 20° of frost, but the plants were uninjured. Such specimens as were in exposed positions suffered a little from gales and the cold winds from the Atlantic. *Interested, Co. Galway, Ireland.*

LETCHWORTH GARDEN DESIGN EXHIBITION AND COMPETITION.—The following interesting competition has been instituted by the Letchworth Garden City authorities:—Class 1.—Design for gardens of a suburban residence, drawings of which will form part of the particulars furnished to each competitor; these drawings will include a site plan giving levels. Class 2.—Design for gardens for above to include a Rose garden. Class 3.—Design for gardens for above to include a Kelway herbaceous border. Prizes: Class 1, first prize, £5; Class 2, first prize, £3 3s., given by Robert Harkness, Rose grower, Hitchin, Herts; Class 3, first prize, £5; second prize, £3 10s., both given by James Kelway & Sons, Langport, Somerset. Class 4.—Design for gardens for a block of ten cottages to be built as a speculation on a corner site, six facing east and four facing north. Drawings, including site plan with levels shown thereon, form part of the particulars supplied to competitors. Entrance fee for each of the above classes 2s. 6d. For particulars write to Estate Office, First Garden City, Ltd., Letchworth, Herts, inscribing letters "Garden Design Competition." The drawing embodying part of the particulars given to each competitor has been kindly prepared for the purpose by Messrs. Barry, Parker & Raymond Unwin, architects, Letchworth. All designs sent in for the competition, which are to reach the Estate Office, First Garden City, Ltd., Letchworth, not later than June 1, must bear a *nom de plume* only, and must be accompanied by a sealed envelope giving the author's name and address. Designs sent in for Class 3 are to become the property of Messrs. James Kelway & Sons. *F. J. C.*

A CLIMBING ACONITE.—It would be interesting to learn whether the climbing Aconite from China, introduced by Messrs. Vilmorin, Andrieux et Cie, Paris, and mentioned on p. 218 of the *Gardeners' Chronicle*, is identical with, or differs from, Aconitum Hemsleyanum, such as Messrs. Barr & Sons have in their Long Ditton nursery, and which I saw growing there in the autumn of 1906, then fully 5 feet in height, forming a really lovely climbing subject. To see a true Monk's Hood climbing in that manner was novel and interesting. The plant was treated as a hardy perennial, and was very ornamental. I do not know whether it produces seeds in this country. *A. D.*

RHODODENDRON × FOSTERIANUM.—On p. 197 of the issue for March 28 last there appeared some notes on Greenhouse Rhododendrons, and a remark which suggested it is difficult to determine which variety of a number mentioned is the best to grow. We find that R. Fosterianum is by far the best both as regards growth and flowers. It is of much freer habit; the flowers are very much larger than any of the others, and they are exceedingly fragrant. Perhaps readers will remember the fine plant that was exhibited from these gardens at the R.H.S. meeting held on April 2, 1907. If plants of each of the varieties named on p. 197 were grown together and afforded the same treatment, R. Fosterianum would prove the best. We have Countess of Haddington planted outside, also R. Gibsonii, Mrs. James Shaw, Countess of Sefton, Lady Skermsdale, Duchess of Sutherland, and a hybrid between R. ciliatum and R. Edgeworthii, and these have been in the open for several years. *W. A. Cook, Leonardslee Gardens, Sussex.* [Our correspondent enclosed flowers of R. × Fosterianum.—ED.]

SOCIETIES.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

MARCH 19.—*Committee present:* Messrs. E. Ashworth, Leemann, Cypher, Ashton, Shill, Ball, Cowan, Ward, Walmsley, Warburton, Parker, Keeling, and Weathers (hon. sec.).

J. MCCARTNEY, Esq., Bolton (gr. Mr. Holmes), gained a Silver Medal in the competition for Cattleyas and Lælias, also a Silver Medal for a miscellaneous group of Orchids.

S. GRATRIX, Esq., Whalley Range (gr. Mr. Shill), exhibited a collection of good plants, one of the most important being Cattleya × Undine, "Gratrix's variety," which was awarded a First-Class Certificate. Odontoglossum × ardentissimum var. virginale, and Dendrobium × Chessingtonensis gained similar awards, while Awards of Merit were voted to Cattleya Schröderæ variety "Niobe," C. S. variety "William Duckham," and Odontoglossum crispum variety "Harmony."

H. J. BROMILOW, Esq., Rainhill (gr. Mr. Morgan), staged a group of Cypripediums in the "Sander" competition. (Silver-Gilt Medal.) A distinct form of Cypripedium Godefroyæ labelled C. G. variety Marjorie received an Award of Merit, and the same distinction was conferred on Cypripedium × Lemoniana, C. villosum, Rann Lea variety, C. × Olga Bagshawe variety The Gem.

R. ASHWORTH, Esq., Newchurch (gr. Mr. Fletcher), was awarded a Silver Medal for a group of Odontoglossums, in which were several distinct O. crispum hybrids.

G. SHORLAND BALL, Esq., Burton, Westmoreland (gr. Mr. Herdman), staged a number of good plants, amongst which Cypripedium × Adrian Lefebre, C. × Alfred Dimmock, and C. × Yellow Prince and Dendrobium × xanthocentrum received Awards of Merit.

Dr. Hodgkinson, Wilmslow (gr. Mr. Woore), obtained a First-Class Certificate for Cymbidium Sanderi.

Z. A. Ward, Esq., Northenden (gr. Mr. Weatherley), was awarded a Silver-Gilt Medal for a splendid exhibit of Odontoglossums. Awards of Merit were granted to Odontioda × Bohnhofiæ, O. × Rolfeæ, Ward's variety, and O. × ardentissimum, Ward's variety.

A. Warburton, Esq., Haslingden (gr. Mr. Dalgleish), staged a fine exhibit of Orchids in three sections, viz., Cypripediums, Cattleyas, and Lælias, gaining Silver Medals for the two first-named and a Silver-Gilt Medal for the last-mentioned exhibit. First-Class Certificates were awarded to Cypripedium × Stepmanii variety superba, Cattleya × Dormaniana, Warburton's variety (a richly coloured form), Odontoglossum × ardentissimum var. xanthotes, O. × Lambeauianum "Purple Gem," and O. crispum variety Perfect Gem (see fig. 104). This is a finely-marked variety of splendid proportions; the spotting is dark purple coloured on a pure white ground. Awards of Merit were voted to Cypripedium × Œdippe variety superba, Cattleya Schroderæ variety Prunus, Cattleya × Miss Harris variety E. Ashworth, and Cattleya × Mont Blanc.

Messrs. H. Low & Co., Enfield, staged a fine array of Dendrobium species and hybrids, some good forms of D. × splendidissimum being prominent. (Bronze Medal.)

Odontoglossums in variety, and they were flanked on either side by plants of Dendrobium splendidissimum, D. nobile var. nobilius, and Masdevallia Veitchii. In the foreground were some choice Lycastes, Lælio-Cattleya hybrids, and Cypripediums, while the group also included two large banks of seedling Dendrobium nobile virginalis, all of which were raised by this firm. The exhibit was staged in a very effective manner, and was one of the best displays of Orchids ever shown at Manchester. (Gold Medal and a Special Vote of Thanks.)

Another beautiful display of Orchids was made by Messrs. Charlesworth & Co., Bradford, who staged a large group of plants, every one of which was worthy of individual inspection. The finest plant in the group was Odontoglossum × His Majesty, which is not far removed from O. crispum. The flower is 4 inches in diameter, of perfect shape, with densely-blotched sepal and petals, and a splendidly-proportioned lip. Brasso-Cattleya × Bradshawiæ var. superba was seen for the first time in Manchester. In this group were also some notable varieties of Lælio-Cattleya × callistoglossa, a pleasing form of Lælio-Cattleya × luminosa, a collection of Lælia cinnabarina, and another of L. flava hybrids. (Gold Medal.)

Messrs. James Cypher & Sons, Cheltenham, staged a charming group of spring flowers and Orchids. One of the best of these latter plants was Lælio-Cattleya × callistoglossa var. The Sultan. There were also many well-grown and

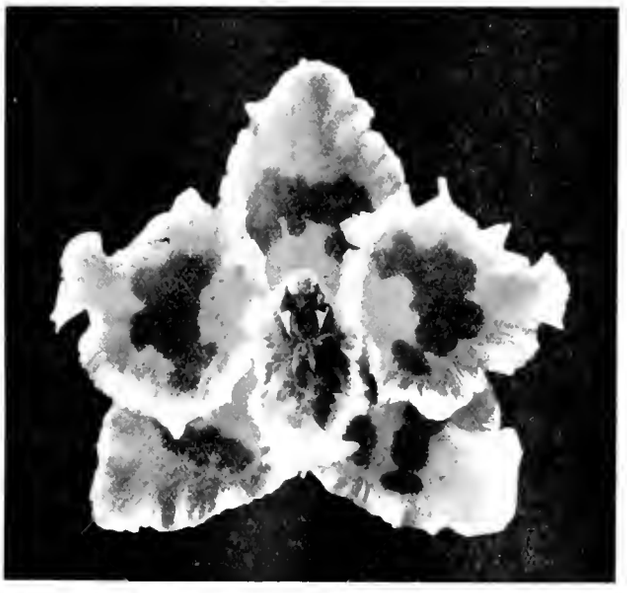

Fig. 104.—Odontoglossum crispum "Perfect Gem," as exhibited at the meeting of the Manchester and North of England Orchid Society.

Messrs. Cypher & Sons, Cheltenham, put up a showy group of plants, in which were noticed many good forms of Cattleya Trianæ and C. Schröderæ, Dendrobiums, and Cypripediums. (Silver Medal.)

Mr. D. McLeod, Chorlton-cum-Hardy, staged a few Cypripediums and a quantity of cut flowers of Odontoglossum crispum and hybrids.

Messrs. Moore, Ltd., Rawdon, Leeds, were awarded a Bronze Medal for a miscellaneous collection of Orchids.

EXHIBITION IN THE ST. JAMES'S HALL.

April 1, 2.—An exhibition under the auspices of the above society was held in St. James's Hall, Manchester, on these dates. This is a very large building, but it was well filled with exhibits, and the society is to be congratulated upon the success of their efforts.

One of the most important displays was made by Messrs. Armstrong & Brown, Tunbridge Wells, Kent, whose exhibit occupied a stage measuring 60 yards in length, and having a width of 9 yards. The subjects consisted principally of Dendrobiums, with here and there a choice specimen of some other Orchid. The centre of the group was composed of flowered Odontoglossums; a specimen of Odontoglossum triumphans var. Othello, with nine spikes of flower; a fine form of O. × excellens, Cymbidium × eburneo-Lowii, some good forms of Miltonia vexillaria; Cattleya intermedia var. nivea, with a fine inflorescence; Dendrobiums in variety, Oncidium varicosum Rogersii, well-flowered plants of Oncidium concolor, &c. (Gold Medal.)

E. Ashworth, Esq., Wilmslow (gr. Mr. Holbrook), put up a tastefully-arranged group consisting of some choice forms of Cattleya Trianæ, Odontoglossums in large variety, including forms of O. crispum, O. triumphans, O. Pescatorei, O. polyxanthum, O. Hallii, and O. cirrhosum; Masdevallia Veitchii, Cypripedium Rothschildianum, Lycastes, and several Lælio-Cattleya hybrids.

The Liverpool Orchid & Nursery Co., Liverpool, made a bold display with popular Orchids, chiefly Odontoglossums, Dendrobiums, some good forms of Cattleya Schröderæ, and various forms of Cypripediums. (Silver-Gilt Medal.)

A. J. Keeling & Sons, Bradford, were awarded a Silver Medal for a miscellaneous group of Orchids.

J. McCartney, Esq., Bolton (gr. Mr. Holmes), was awarded a Silver Medal for a group, in which were many good Cattleyas, several forms of C. Trianæ and C. Schröderæ being prominent; also varieties of Dendrobium and Odontoglossums.

Messrs. Sander & Sons, St. Albans, had an effective group of choice plants, in which were noted some good varieties of Lælio-Cattleya × callistoglossa, a fine strain of Dendrobium Wardianum, Lælio-Cattleya × Empress of Russia, Phaius Wallichii, Cattleya intermedia var. Snowflake, Cypripedium × Lord Derby, Cattleya Schröderæ var. "Queen Alexandra," C. Schroderæ "The Bride," Odontoglossum Uro-Skinneri, a fine form of Cypripedium Rothschildianum, and a plant of Lælio-Cattleya Choletiana, in addition to a fine display of Anthuriums. (Silver-Gilt Medal.)

Mr. J. Robson, Nurseryman, Altrincham, exhibited Dendrobiums in variety, Odontoglossums, and a small collection of Cypripediums. (Silver-Gilt Medal.)

A. Warburton, Esq., Haslingden (gr. Mr. Dalgleish), staged a group of choice plants. Odontoglossum "The King" was one of the most notable; the plant was carrying two flowers, each of a fine, rich colour. Several other fine Odontoglossums were included in the group, also a beautiful collection of Miltonia vexillaria. (Silver-Gilt Medal.)

William Bolton, Esq., Warrington, staged Cattleyas and Odontoglossums in variety. (Silver Medal.)

A. W. Jensen, Esq., Hayward's Heath, displayed a group of Cattleya Schröderæ, all of which were selected forms. (Bronze Medal.)

Messrs. Moore, Ltd., Rawdon, Leeds, exhibited a miscellaneous group, consisting of Odontoglossums, Cypripediums, Phalænopsis, and some plants of botanical interest. (Silver Medal.)

Z. A. Ward, Esq., Northenden (gr. Mr. Weatherly), exhibited a meritorious group of Odontoglossums, including many known species and several choice hybrids. (Silver-Gilt Medal.)

Messrs. J. & A. A. McBean, Cooksbridge, exhibited a number of plants of Odontoglossums, principally O. crispum and its varieties, all of which were excellently flowered. (Silver-Gilt Medal.)

Norman C. Cookson, Esq., Wylam-on-Tyne, exhibited Phaius × Clive and Phaio-Calanthe delicata, both of which were much admired.

J. E. Williamson, Esq., Stretford, was awarded a Silver Medal for a group consisting of Odontoglossums, Dendrobiums, Cypripediums, and a well-cultivated plant of Angræcum sesquipedale.

Mr. E. G. Mitchell, Sale, exhibited Dendrobium seedlings.

R. Ashworth, Esq., Newchurch, was awarded a Silver Medal for a choice exhibit of Odontoglossums. Several pleasing hybrids of spotted varieties of O. crispums were included in the group.

H. J. Bromilow, Esq., Rainhill (gr. Mr. Morgan), was awarded a Silver Medal for a group consisting of Cypripediums, Cattleyas, and Dendrobiums.

Messrs. Hugh Low & Co., Enfield, staged a showy group of Orchids. Cattleyas formed the principal feature, and they included some choice forms of Cattleya Trianæ. They also showed Odontoglossums in variety, Dendrobium barbatulum, and a number of Oncidiums. In addition to the Orchids, they also made a bright display with Carnations. (Gold Medal.)

Messrs. Cutbush & Son, Highgate, showed a collection of forced shrubs, including Laburnums, Lilacs, Prunus, Staphylea, Magnolias, Azaleas in variety, &c. (Gold Medal.)

Messrs. Dickson, Brown, & Tait, Manchester, were awarded a Silver Medal for a miscellaneous collection of plants, the chief feature of which was a display of Primula × kewensis.

Messrs. Frank Dicks & Co., Manchester, were awarded a Silver Medal for Cinerarias and floral devices.

AWARDS.

First-Class Certificates were awarded to Brasso-Cattleya × Thorntoniæ var. Boydiæ; Dendrobium nobile virginalis var. magnificum, Cymbidium × Holfordianum, all of which were shown by Messrs. Armstrong & Brown, Tunbridge Wells; Brasso-Cattleya ×

Bradshawiæ superba, Phalænopsis Sanderiana, Wigan's variety, and Odontoglossum × His Majesty: these three were exhibited by Messrs. Charlesworth & Co., Bradford. Odontoglossum × Lambeauianum "The Lady," Odontoglossum × L. Perfection, O. crispum var. "King of England," Miltonia vexillaria, Vine House var., these four were shown by A. Warburton, Esq., Haslingden; Lælio-Cattleya × callistoglossa var. "The Sultan," shown by James Cypher & Sons, Cheltenham; Phaius × Clive, from the gardens of Norman C. Cookson, Esq., Wylam-on-Tyne; Cypripedium × microchilum var. Honoræ, and C. concolor var. "Emperor"; these two were exhibited by H. J. Bromilow, Esq., Rainhill; and Odontoglossum × ardentissimum var. album, shown by Z. A. Ward, Esq., Northenden.

Awards of Merit were awarded to Dendrobium × Geo. Woodhams, D. × Alice Bound var. giganteum, Lycaste Skinneri var. amœna, Cypripedium × Braceyanum, C. hirsutissimum var. giganteum, Lycaste gigantea, all of which were shown by Messrs. Armstrong & Brown, Tunbridge Wells; Odontoglossum × exultans, from the gardens of W. Thompson, Esq., Stone; Brasso-Cattleya × Thorntoniæ var. gigantea, shown by Messrs. Cypher & Sons; Phaio-Calanthe × delicata, exhibited by Norman C. Cookson, Esq., Wylam-on-Tyne; Cypripedium × Euryades var. superbum, Cypripedium × Wootonii, Rann Lea variety, both shown by H. J. Bromilow, Esq., Rainhill; Dendrobium × Chessingtonense, "Keeling's variety," shown by Messrs. A. J. Keeling & Sons, Bradford; Odontoglossum × Atalanta and Odontoglossum × æthiopica, the two last-mentioned being exhibited by R. Ashworth, Esq., Newchurch. *P. W.*

Obituary.

David Donald.—We regret to record the death of Mr. David Donald, who passed away at his residence, Beulah Road, Walthamstow, on April 2, at the age of 83 years. The late Mr. Donald was for a period of more than 30 years gardener to Gurney Barclay, Esq., of Knott's Green, Leyton, and since the death of that gentleman, some 10 years ago, has lived in quiet retirement. In addition to being a first-class gardener, deceased was a successful exhibitor and a judge at flower shows, also a contributor to the horticultural Press. He will, perhaps, be best remembered by his exhibits at the National Chrysanthemum Society's shows held at the old Westminster Aquarium, where his excellently-trained plants of Chrysanthemums were always a notable feature.

THE WEATHER.

THE WEATHER IN WEST HERTS.

Week ending April 8.

Frequent showers of rain and hail. On the whole this was rather a warm week, but the temperature was very variable. For instance, on the warmest day the temperature in the thermometer screen rose to 58°, and on the coldest night the exposed thermometer registered 11° of frost. The ground is now both at 1 foot and 2 feet deep about a degree colder than is seasonable. Frequent showers of rain and hail fell on four days, but the total measurement was only about half an inch. Nearly three-quarters of a gallon of rain-water came through the percolation gauge on which short grass is growing, and rather more than a gallon through the bare soil gauge. The sun shone on an average for 4½ hours a day, which is about a quarter of an hour a day short of the average duration for the time of year. In the early part of the week the wind remained as a rule high, and in the windiest hour the mean velocity amounted to 21 miles—direction west. The average amount of moisture in the air at 3 p.m. exceeded a seasonable quantity for that hour by 7 per cent.

Our Underground Water Supply.

With March came to an end the winter half of the present drainage year. The total rainfall for these six months exceeded the average quantity by 2½ inches, which is equivalent to an excess of 54,970 gallons on each acre in this district. At the same time last year there was an excess of 29,860 gallons per acre. *E. M., Berkhamsted, April 8, 1908.*

Answers to Correspondents

Bulbs Diseased: *E. P.* It is possible the bulbs were not all planted in the same manner. Much depends upon the depth at which they were planted and upon the texture of the soil. There might easily be a difference of both in the half-moon-shaped and centre beds. The soil in the centre bed might, for instance, have been very loose in texture, allowing the frost to reach the bulbs and thus predispose them to disease. As the bulbs planted in all the beds were from the same parcel, it is evident that they were healthy at the time of planting. Those you sent were attacked by the Sclerotium disease, and possibly some sclerotia were present in the ground from a previous season. Nothing can now be done to arrest the disease, but the bulbs should be dug up and burned, or the Sclerotium will spread to the healthy ones.

Chrysanthemums: *G. H. H.* Your plants appear to be attacked by Septoria Chrysanthemi, a new disease described by Mr. Salmon in our issue for September 21, 1907, p. 213, with illustrations.

Clematis Jackmannii: *Philanthos.* During the years which your plant has been left unpruned, it must have made much useless wood, and although you might not like to see it pruned severely now, it will eventually be all the better for the plant. It is by a judicious use of the knife that flowers of the greatest size and best quality are obtained. The shoots should be shortened to within 9 inches or a foot off the main stem, a few of the very strongest might be left even longer than this, provided they are thoroughly well ripened. All weak growths should be cut away entirely. If pruning is attended to at once, the soil about the roots loosened with a fork, and a top-dressing of manure or good leaf-mould applied, the plant will soon produce an abundance of good wood capable of flowering freely.

Fumes: *Road.* You must remove the varnish, or, failing this, keep the ventilators open a little until the pipes cease to give off any fumes.

Hippeastrum Flower: *H. P.* The flower received is not a double flower in the ordinary sense of the term, but a combination of two flowers. We have seen similar examples.

Hours of Work at Kew: *Interested.* The gardeners work from 6 a.m. to 6 p.m., with three-quarters of an hour (8 to 8.45) for breakfast, and one hour (12 to 1) for dinner. They have afternoon leave from 12 o'clock noon on alternate Saturdays. During the four winter months (November to February) they work from daylight to dark.

Lilium Auratum: *M. G.* The compost should consist of good, fibrous loam, leaf-mould, and a liberal addition of sand, or, if the loam is not sufficiently fibrous, some peat may be added. Good drainage is very necessary, and after this has been provided the pots should be filled about half full with the compost. Put a layer of sand for the base of each bulb to rest upon; do not press the bulbs down, but leave the soil loose beneath them. A little sand and charcoal may be shaken among the scales, and the bulbs should only be buried about half their depth. Keep the soil moderately moist, but do not pour water upon the bulbs. The pots may be placed in a frame or in the greenhouse under the stage until they show signs of making growth. After this time the pots should be filled up with the compost already mentioned, but it may receive the addition of a little manure. Roots will grow from the base of the stem, and if the pots are not deep enough to allow of these being covered, the plants will need to be shifted into larger pots. Healthy, home-grown bulbs are frequently placed in the open and covered with cocoanut fibre refuse, but in the case of imported bulbs it is better to leave them exposed, as they are liable to rot when covered.

Manure for Palms: *W. M.* Almost any of the plant fertilisers may be used in very small quantities, but we prefer liquid manure prepared from soot and guano, or from cow manure. Do not apply any manure until the pots have become well filled with roots. Many amateurs put their Palms into pots of too large a size, and apply too much water at the roots. The plants require much atmospheric moisture, but should not be kept in a wet condition at the roots.

Mushrooms: *L. H.* You do not send the complete stems, so that the species is uncertain, but they appear to be edible and not different from the common Mushroom.

Names of Plants: *H. M. W.* Acacia longifolia. —*J. S.* 1, Ixora stricta var. alba; 2, not recognised, send when in flower. You are wrong in suspecting it to be a Psidium.—*W. L.* 1, Curculigo recurvata; 2, Davallia (Microlepia) platyphylla; 3, Mackaya Bella; 4, no flowers, probably Tecoma jasminoides; 5, Diosma ericoides; 6, Dracæna hybrids.—*A. M., Derry.* 1, Cypripedium Ashburtoniæ (a very poor variety); 2, Dendrobium Brymerianum; 3, Brassavola cordata.—*A. W. G.* Jasminum ligustrifolium.—*H. J. C.* Erythronium Dens canis, probably an escape from the garden.—*W. B.* Arrhena-therum avenaceum.

Notice to Terminate Employment: *A. R.* It is usual for head gardeners to receive one month's notice. We do not know if there are special conditions in your case.

Richardia africana: *A. J. K.* It is largely a matter of convenience. Excellent results are obtained with Callas by cultivators who keep them in pots during the whole year, and by others who plant them out at the commencement of the summer and pot them up again before frosts occur in autumn. For ourselves, we prefer the planting-out system for large batches, as less watering is required during summer. If you practise both systems for one season you will not be likely to suffer any loss, and the experience thus obtained will teach you which method will best suit your requirements.

Spiræas Failing to Flower: *W. M.* We cannot determine the exact cause of the flower-spikes damping off, but it may have been the result of the plants receiving a check from drought, draught, or excessive applications of manure after they had started into growth; or it may be that they had not made sufficient roots before attempting to make growth. For early forcing the plants should be placed where there is a little warmth beneath them, and be covered with 3 inches deep of cocoanut fibre refuse; when the growths appear above the surface of the fibre, this material may be shaken off and the plants placed in a light, warm position. Although Spiræas require plenty of moisture, it is possible to over water them, and if the soil becomes sour from this cause the roots will decay and the plants fail to flower.

The "French Garden": *E. B.* The average size for the type of garden described by Mr. Aquatias is two acres, and we are informed that the materials required are as follow:—400 French-made lights, £140; 133 frames for these lights, £50; 2,500 cloches, £100; 600 mats, £40; implements, including three wicker baskets and stands, £18. It is also necessary to provide a large tank for a water supply with the necessary pumps, hydrants, hose, &c., and this will cost from £100 to £400. Provision must be made for 1,000 tons of manure per annum, and the necessary seeds will cost about £5. The net profit realised by an experienced gardener is, after all expenses, including those of the household, have been paid, is about £120 per annum. Radishes are grown as a "catch" crop. They realise from 1s. to 1s. 6d. per dozen bunches. Lettuces realise from 5s. to 16s. per hundred. Carrots sell for about 4d. to 7s. per bunch.

POPULAR SPECIES OF PALMS.

ANYONE acquainted with horticulture during the past 40 years or more can recall many instances of plants which were rare at that time, but have since become extremely popular in gardens. Among them may be included Palms. Half a century ago very few species were cultivated, except in the temperature of the stove, and now they are largely employed, not only for the embellishment of glass structures, but for indoor decoration in various ways, as well as for planting in the flower garden during the summer months, either as specimens sunk in the turf or arranged in groups. In addition to the more or less tender Palms, the value of the hardy species Trachycarpus excelsa (often known as Chamærops excelsa and C. Fortunei) is now very generally recognised.

It is however as pot plants that Palms are most generally grown, and a visit to Covent Garden Market in the early hours of the morning upon a market day will give the visitor some idea of the immense numbers that are now sold in this and similar markets. If some of the large plant nurseries and market-growing establishments be also visited, it will serve to further drive home the importance of the Palm trade, for the plants are cultivated, literally, by the acre. Most of them soon come to an untimely end after sale, hence there is a constant demand for fresh plants, but this need not happen if proper attention be given them, for even in a dwelling-house many Palms may be made to succeed fairly well for several years.

Though Palms now form a regular feature in Covent Garden Market at all seasons of the year, the only one common there 40 years ago was Livistona chinensis (Latania borbonica), which, owing to its somewhat heavy habit of growth, has since become more or less ousted in favour of those kinds that form lighter and more elegant specimens. In those days the Kentias, now the most popular species, were unknown. One of the earliest to cultivate Palms in large quantities for market was the late Mr. Hermann Herbst, of Richmond. His knowledge of Brazil enabled him to obtain seeds of many species, which he thought likely to meet with popular appreciation.

Fortune at once smiled on the enterprise, for with the commencement of the Franco-German war many wealthy people came to this country from the Continent, where foliage plants in those days were more popular than here. They soon singled out Palms as especial favourites, and the taste for them quickly spread. The result was very satisfactory to Mr. Herbst, who, having a large stock of saleable plants, enjoyed a great advantage over other competitors, as the raising of Palms from seeds requires a considerable time.

In order for a Palm to be popular with the public it must possess certain definite characteristics. In the first place, it must not be exacting in its cultural requirements, for if a considerable amount of heat and atmospheric moisture are necessary to keep it in good health it is next to useless for general decorative purposes.

The plant must be free from formidable spines, as these may not only prove a source of danger, but they injure other plants that may be packed with it. For this reason the beautiful forms of Dæmonorops, now known as Calamus, have never become common. It is also necessary that a Palm must be of fairly quick growth, and therefore be capable of making well-furnished specimens in comparatively small pots.

Kentia Belmoreana and Kentia Forsteriana may be quoted as ideal market Palms, but the private cultivator prefers at least a certain amount of variety, as a continual repetition is apt to pall. Of these two species, K. Belmoreana has the fronds more divided, and it forms at least in a young state a dwarfer plant than the other. Where large, bold specimens are required, K. Forsteriana is generally preferred, but K. Belmoreana is a favourite for growing in comparatively small pots. The time can readily be recalled when a guinea each was asked for small plants of either of these Kentias, such as can now be bought for a few pence. The large quantities of seeds that are annually sent to this country from Lord Howe's Island enable the stock to be maintained, despite the vast numbers disposed of every week.

The genus Cocos is an extensive one, but by far the most generally grown of all is Cocos Weddelliana, a charming little species with much divided fronds; indeed, it is one of the lightest and most elegant of Palms. Though a native of Brazil, it is hardier than is generally supposed, and with attention will often hold its own in a dwelling-house for years. While all Palms greatly dislike overpotting, this is one of the most susceptible in this respect. As tall plants from 6 feet to 12 feet in height, Cocos plumosa is perhaps the most popular species. In its earliest stages this has large, simple fronds, but after a time, say, when the above heights are obtained, the fronds become divided into many segments, and in this stage the plant well merits the specific name of plumosa.

Two species of Areca, namely, A. Baueri, from Norfolk Island, and A. sapida, a native of New Zealand, will thrive in an ordinary greenhouse, but they are not much grown as they need larger pots in proportion to their head than many other Palms. Areca lutescens, from Madagascar, needs stove, or at least intermediate-house, treatment. Before Kentias were obtainable this was one of the most popular Palms, but now it is not grown to anything like the extent it once was. A notable feature of this Palm is its habit of pushing out numerous shoots from the base, so that in time it often forms a dense tuft.

Chamærops humilis, the dwarf Fan Palm of Southern Europe, is a very ornamental subject for the greenhouse, and it also succeeds out of doors during the summer. A peculiar feature of this is the individual variations that occur when it is raised in large quantities from seed. It is more marked in this species than in any other Palm that I know, and no fewer than five recognised varieties are mentioned in the Kew *Hand List*. The hardy Trachycarpus excelsa (or Chamærops excelsa) is, apart from its value for planting out of doors, extremely useful when cultivated in pots for various decorative purposes, as its hardiness enables it to be employed for the furnishing of draughty corridors and similar places where more delicate species would soon suffer.

Corypha australis, an Australian Fan Palm with spiny leaf stalks and a harsh, unyielding style of growth, would probably not be much grown but for the fact that, like the Chamærops, it is but little affected by cold draughts short of actual frost.

Geonoma gracilis is a delightful Palm somewhat suggesting Cocos Weddelliana, but its habit of growth is altogether more graceful. As far as my experience goes, it is also of a more delicate constitution. But few market cultivators grow this species, and well-furnished plants always realise good prices.

Latania borbonica is a native Fan Palm of China and Japan, and will thrive in the greenhouse. It was at one time grown almost universally, but has has fallen into disfavour in late years, though I have recently noted signs of increased interest in the plant.

Several members of the genus Phœnix are

valuable for decorative purposes, though the true Date (Phœnix dactylifera) cannot be included under that head. The nomenclature of the genus is in a very confused state, and I am not sure that all the forms grown as P. canariensis rightfully belong to that species. At all events, P. canariensis itself is one of the best of Palms for the embellishment of the conservatory, or for placing out of doors during the summer, while few, if any, surpass it as a plant for the dwelling-house. Other good species are P. reclinata and P. rupicola, while that delightful little gem among Palms, P. Roebelinii, is making rapid headway in popular favour. For its successful culture, however, stove heat is necessary.

Rhapis flabelliformis is a Japanese Palm that pushes up suckers freely, so that in time it forms quite a mass of stems. It is essentially a greenhouse species, and is very popular for decorative purposes in its native country.

Seaforthia elegans is rarely seen nowadays, but before Kentias were so generally grown this Palm was cultivated in considerable numbers.

Culture.

When used for decorative purposes many of these Palms have to be placed in ornamental pots or vases. Such being the case, it is a great advantage to keep them in as small pots as possible, consistent with their remaining in good health. Fortunately, most of the ordinary decorative Palms readily lend themselves to this treatment, while it is easy to injure them by overpotting. There are now many stimulating manures on the market that can be used without any unpleasant smell, and when Palms are much pot-bound they are greatly benefited by occasional applications. Care must be taken to strictly follow the instructions, for if too much is applied the growing tips of the roots are apt to be injured, and the plant soon falls into ill-health. As a rule, no water should be allowed to stand in the saucers or other receptacle, though this rule may be relaxed in the case of Phœnix canariensis, whose roots, when much pot-bound, delight in this extra moisture.

Cleanliness is a very important factor in the successful cultivation of Palms, hence a frequent sponging of the leaves with tepid water and a little soap is beneficial.

It may be pointed out that while the names as above given are those in general use, botanists and horticulturists are by no means of one accord with regard to the nomenclature of the different members of the Palm family. Thus Kentias are to the botanist Howeas, from Lord Howe's Island, Areca Baueri is Rhopalostylis Baueri, Areca sapida is Rhopalostylis sapida, Areca lutescens is Chrysalidocarpus lutescens, Corypha australis is Livistona australis, Latania borbonica is Livistona chinensis, and Seaforthia elegans is Archontophœnix Cunninghamii. W.

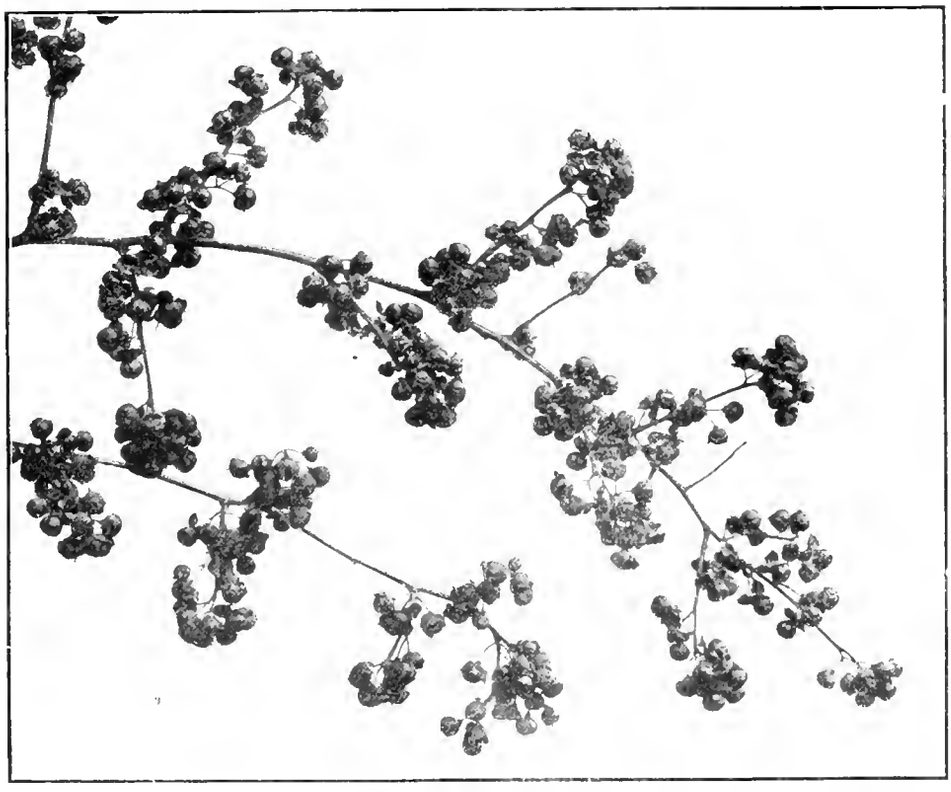

Fig. 105.—Flowering spray of Celastrus articulatus.

CELASTRUS ARTICULATUS.

During the past winter no deciduous climber has made so effective and continuous a display as this Celastrus from Northern Asia. It is a comparatively recent introduction, having been raised at Kew, in 1891, from seeds sent by Professor Sargent, of the Arnold Arboretum. It is not yet so well known in gardens as it deserves to be or is likely to become. Of very vigorous growth, it is admirably adapted for covering trees that are past their best, when, instead of uprooting them, it may be thought worth while to utilise them as supports for ornamental climbers. This Celastrus is a twiner, and once attached to a suitable support, soon makes good its hold. A group of plants in the Kew Arboretum growing over some rough branches stuck in the earth set an enormous quantity of fruit last autumn, and for several months were singularly attractive. During November, December, and January there was nothing out of doors that made so fine a display. The Celastrus is a near ally of Euonymus, and, as in this genus, the species owe their beauty mainly to the fruits. In the plant we are now considering the fruit has at first the form of a pea-shaped capsule. This capsule is three-valved, and, as the fruit ripens, the valves open and become reflexed. It is then that the full beauty of this climber is revealed, for the inside of the valves is golden yellow, and the large seeds are of a shining scarlet. The plants in cultivation are probably of Japanese or Chinese origin, but the species is widely spread over North-East Asia. W. J. B.

FRUIT FORCING AT GUNNERSBURY HOUSE.

I recently visited these well-known gardens, and was much interested in the forcing of fruits which is extensively undertaken by Mr. James Hudson, the gardener. The forcing of fruit trees in pots is a special feature at Gunnersbury House Gardens, and many of the trees were, at the time of my visit, in full blossom, but others had set large crops of fruit. There were Peaches, Nectarines, Plums, and Figs. These trees have been forced each season for more than ten years, and some are of a greater age than this, which disproves the general belief that such trees do not last long and are costly to replace. In this connection I may state that when visiting a garden last year in which I was employed some 40 years ago, I saw the same trees that were there in my time bearing good crops, though in very large pots. Several houses at Gunnersbury House are filled with pot-trees, and the earliest have fruits about as big as Walnuts, at which size they are thinned, for thinning is not done so early in the case of potted trees as with those that are planted out.

In the early house are six rows of trees, and taking into account their age—some are from 10 to 15 years old they are splendid specimens of pot culture. The size of the pots at once impresses one as being small, and here I think is one of the secrets of success—for small pots, with annual repotting, careful stopping of the shoots, and suitable feeding, are the main requirements. Pots having a diameter of 9 to 12 inches are used, and the larger size mentioned is rarely exceeded, though some of the trees almost touch the glass with their shoots. Amongst the Peach trees I noticed some fine specimens of Duchess of York, Duke of York, and others. The Peaches and Nectarines are also represented by the best of the mid-season kinds, such as Crimson Galande, Dymond, Grosse Mignonne, Sea Eagle, the Nectarine Peach, and Pine Apple Nectarine, Rivers' Orange, Humboldt and others. Cardinal Nectarine is much grown, also Early Rivers, and others, including Victoria, a fruit having the same flavour as the Stanwick Elruge, and which forms a grand tree for pot culture. When the trees were opening their flowers a hive of bees was placed in the house, and this was transferred from one house to another as the blossoming proceeded. There are very large crops of Plums, and though some of the trees are small, the fruits will require a severe thinning.

Cherry trees are a great feature in another house. The varieties of Cherries cultivated in these gardens are numerous, Guigne Annonay, a fine black fruit, being the earliest to ripen, is of excellent flavour, and ripens ten days earlier than Early Rivers; it is a great bearer in pots. Guigne Annonay is largely grown and is a favourite. Belle d'Orleans is also grown for its early fruits, and the May Duke for its pollen, which is valuable for setting the fruits of other varieties. Some of the late kinds, such as

Governor Wood, Bigarreau Napoleon, and Bigarreau de Schreken have set grand crops.

Of Plums, all the best of the Gages are represented, including Jefferson. Count Althann's Gage is a splendid late red Plum.

A large house is entirely devoted to pot Figs, and fruits of the variety St. John's are gathered daily. Mr. Hudson also cultivates the Pingo de Mel variety largely, and holds it as valuable as the St. John's, but I have always been under the impression that Pingo de Mel was not so valuable a variety, as it has a more spreading growth and a deeper-coloured fruit; at any rate, it is a grand Fig for forcing.

A large house, which may aptly be called "The Store," is filled with trees and kept as cool as possible to provide a succession. Here are large quantities of Peach, Nectarine, Plum, and Fig trees. Other houses are filled with Strawberries; the earliest house is well furnished with fruits that are at their final swelling stage. The variety is Royal Sovereign. But, though this is largely grown, Mr. Hudson is impressed with the qualities of Laxton's Progress, and this is on trial with Royal Sovereign. The plants in the second house are equally good, but in a later stage of growth, and there are large supplies of Strawberries in cold frames to form a succession. *G. Wythes.*

Fig. 106.—sprays of darwinia hookeriana: flowers greenish-white.

THE GENUS DARWINIA.

This genus was named in honour of Dr. E. Darwin, author of *The Botanic Garden*, a poem in two parts published in 1795. In addition to the name of Darwinia, plants in this genus have been assigned several other generic names. The reasons for this will be perhaps best understood by the following explanation, taken from a paper by George Bentham, P.L.S., read before the Linnean Society on February 2, 1865, "described and figured by the late Mr. Rudge in the eleventh volume of the *Linnean Transactions* as Darwinia." "Owing to Mr. Rudge having overlooked the minute calyx-lobes, and misunderstood some other points of its structure, it was generally referred to Monochlamydeæ, where it naturally did not occur to De Candolle to seek for it when working up the Myrtaceæ for the *Prodromus*. He therefore described the latter in the *Prodromus*, and figured it in his memoir on Myrtaceæ, as a new genus, under the name of Genetyllis. Unfortunately he also overlooked the staminodia, expressly distinguishing it from Chamælaucium by their absence. Lindley, therefore, in his account of the Swan River vegetation appended to the *Botanical Register*, having to describe three additional species, established another genus under the name of Hedaroma." "Endlicher also, about the same time, in the second volume of the *Annalen des Wiener Museums*, proposed a fourth genus under the name of Polyzone."

The genus is found only in Australia. Mueller, in his second census of Australian plants, enumerates 37 species. All are evergreen, and shrubby in habit. An interesting point about the Darwinias is the highly-coloured bracts surrounding the flowers. It is to these that the plants owe their decorative value, the flowers themselves being small, and enclosed within the bracts. The campanulate inflorescences are terminal, and last for a long time in perfection on the plants. The bracts enclosing the flowers can be seen fully six months before they are fully developed. These are freely produced, there being some 250 on the plant, each spray on an average bearing six flowers.

The species of Darwinia, like the genus, have at various times had several names. As far as I am aware only two species are in cultivation at the present time in this country. These are D. Hookeriana and D. macrostegia. A third species, D. fimbriata, with rose-coloured bracts, was introduced by Messrs. Veitch, of Chelsea, in 1864, but has apparently been lost to cultivation. It has figured in the *Botanical Magazine*, tab. 5468, as Genetyllis fimbriata. Judging from dried specimens, one of the most decorative species is D. Meisneri, collected by Drummond in South-western Australia, but I can find no record of its being cultivated in this country.

Darwinia Hookeriana, Bentham, in the *Journal* of Linnean Society, IX. (1867), p. 179 = Genetyllis macrostegia, Hooker, in *Botanical Magazine*, tab. 4860 = G. fuchsioides, Hort.—The linear-oblong leaves, about half an inch in length, are freely scattered over the thin red stems, giving the plant a heath-like appearance. The inner bracts of the campanulate involucre surrounding the flowers are bright red in colour, 1 inch in length, ½ inch broad, two or three outer ones shorter, greenish-red, passing to stem leaves. Flowers: small, greenish-white, sessile, usually in 6's enclosed in terminal heads, within the bracts. Introduced by Drummond, who collected seeds in Western Australia. The plant, of which a spray is figured, is 3 feet in height; with age they attain much greater dimensions.

D. macrostegia, Bentham, in *Journal* of Linnean Society, IX. (1867), p. 179 = Genetyllis tulipifera, Hooker, in *Botanical Magazine*, tab. 4868. Hedaroma tulipiferum, Lindley, in *Gardeners' Chronicle* (1854), p. 323.—The elliptical-oblong leaves are scattered, ½ inch to ¾ inch long. The inner bracts of the campanulate involucre creamy-white, striped and splashed with red, about 1½ inch long, outer ones shorter, and with rather more colour, several of the lowest merging into stem-leaves. In appearance this species is rather more robust than the preceding. A plant figured in the *Gardeners' Chronicle* for 1879, p. 785 (now reproduced), was 7 feet 6 inches in diameter and 4 feet 6 inches high. As in the case of D. Hookeriana, this plant was also introduced by Drummond. Exhibited as a new plant, it received a Silver Medal at the Horticultural Society's show held at Chiswick on May 13, 1854.

Cultivation.

Propagation is effected by cuttings, the points of well-ripened side shoots being the best. September and spring are the most suitable seasons for inserting the cuttings; the month of September is preferable, the growths at that time being moderately hard. Cuttings 1 inch to 1½ inch in length will be found the most suitable. Pots 3 inches in diameter are a useful size for the cuttings. Make the pots half full with broken crocks, and over these place a layer of rough peat, filling up the pot with finely sifted peat and sand, the surface to the depth of ¼ inch being all sand. Insert the cuttings fairly close together and make them firm. Leave sufficient space round the edge of the pot to permit of a bell-glass being placed over the cuttings. An atmospheric temperature of 50° to 55° Fahr. will be suitable. If convenient the pots will be better plunged nearly to the rim in ashes in a propagating frame. Remove the bell-glasses every morning and wipe them, otherwise if there is an excess of moisture the leaves will fall. When the cuttings are putting forth roots the bell-glasses may be tilted and finally dispensed with altogether. By April or May in the case of cuttings inserted in autumn, and September when inserted in spring, they should be ready for potting off singly in small pots. Use finely sifted peat and coarse sand and pot firmly. The soil must be used in a moist condition, as it is not advisable to water the young plants for several days after potting. Give them a light position on a moist stage in a house in which the heat is kept at 50° to 55° Fahr. until they are nicely rooted. Afford shade from bright sunshine until the plants have become well established in the pots, after which stage the points of the shoots may be removed. During winter a temperature of 5° lower will be more suitable. In the following spring the plants should be shifted into 4-inch pots, and again in autumn if they have done well a further shift may be necessary, this time into 6-inch

pots, as the plants in a young state must not be allowed to get root-bound. A minimum temperature of 45° is sufficient for large specimens. In August when the bracts have formed, the plants may be stood outside in a position sheltered from the mid-day sun. A certain amount of attention will be necessary from time to time in stopping and tieing the plants to obtain good specimens. The heads of flowers should be picked off as soon as the colour shows signs of fading. Peat, coarse sand, and a little broken charcoal form the best compost for Darwinias. Mildew sometimes attacks the plants, but if they are dusted with sulphur it will destroy the pest. In potting Darwinias more space should be left for watering than is usual with most plants. Large specimen Darwinias were very popular for exhibition 20 to 50 years ago. This was no doubt in a large measure due to the length of time the plants retain their beauty when in flower; for three or four months, or even more when grown quite cool, the bracts keep a good colour. *A. O.*

COLONIAL CORRESPONDENCE.

HÆMANTHUS KATHERINÆ.

IN the *Gardeners' Chronicle* for February 1 there is a figure and some remarks on Hæmanthus Katherinæ, and in the accompanying note it states that "Mr. Baker named it in compliment to Mrs. Katherine Saunderson, wife of the gentleman who first sent dried specimens, which he had collected in Natal, to be determined at Kew." This is an error which ought, I think, to be corrected. The lady who sent the specimens, and I think bulbs, of the plant to Mr. Keit, asking that they should be sent to Kew, was Mrs. Katherine Saunders, the wife of Mr. J. Renault Saunders, the manager and part owner of the Tongaat Sugar Estate, and the mother of Sir Charles Saunders, of Zululand. Mrs. Saunders was an accomplished artist, and painted numbers of our wild flowers in a very beautiful manner. Some of these paintings were sent to the late Professor Harvey for naming, and some also to Kew. Both Mr. and Mrs. Saunders died some years ago. Mr. J. Sanderson, who sent numbers of dried plants to Kew, died many years ago; his speciality was Orchids. He made many coloured drawings of these plants, which were for some years in my possession, but the late Mrs. Sandersoa did no botanical work to my knowledge. Mr. Sanderson was editor and proprietor of the *Natal Colonist*, and the well-known Sandersonia aurantiaca was named after him. *J. Medley Wood, Director, Natal Botanic Gardens.*

PLANT NOTES.

TROPÆOLUM TRICOLORUM.

THIS decorative greenhouse plant is in flower during March and April, and few subjects furnish a brighter display than this Nasturtium when climbing up to the glass roof, a position in which all its fiery-coloured flowers are seen to advantage. While this plant is making its growth, almost daily attention is necessary to train the slender shoots in the direction required, as they soon become entangled owing to each one of the many tiny leaves encircling itself around the support. The plant is frequently trained over a balloon-shaped trellis, but I consider the flowers are shown to greater advantage when the shoots are trained up strings fastened to form festoons on the lower parts of the roof of a cool greenhouse. During bright days, a light spraying with clear water during the afternoon has the effect of destroying red spider should it be present on the foliage; this pest will be very troublesome if the roots are allowed to suffer from dryness. When the flowering period is over and the foliage begins to turn yellow less water should be given, and as soon as the growths are thoroughly ripened they should be cut off and the pots containing the plants be removed to a sunny position, and be kept comparatively dry until the end of September. After this period of rest, a good soaking of water should be given to the roots, and immediately new growth is apparent the old soil should be shaken from the roots, and the plants be re-potted into 7-inch pots, care being taken that the tiny, brittle growths are not damaged in the process. My former practice was to re-pot these plants while they were dormant, but I find they succeed better if they are first started into growth. The pots should be well drained, and the soil should consist of a mixture of turfy loam and a little peat, with a good sprinkling of coarse silver sand. When the potting is finished, a crooked peg should be driven into the centre of each pot to fasten the string for training.

CANTUA DEPENDENS.

THIS plant is not often seen in gardens, either under glass or in the open. Its season of flowering is February, when it should be given a little warmth, such as is afforded Primulas, Cyclamen, and other spring-flowering plants. In these gardens it is planted out in a narrow border against a dark wall, and the growths are trained up to the glass roof, where its hanging, funnel-shaped flowers are seen to advantage. This species (which is identical with C. buxifolia) is considered sufficiently hardy in the West of England to withstand the winter if planted in a sheltered corner, but I have never seen it in the open in Devon, though I believe it is so planted in Cornwall, where the temperature is not so changeable as in this part of Devonshire. When grown under glass, the plant is susceptible to attacks of red spider, especially during the summer months; the syringe should therefore be freely used both in the early mornings and again towards 5 p.m. The shoots should be thinly trained for the purpose of producing stout flowering growths. The roots absorb much moisture during the summer months, and applications of weak manure water made either from cow, sheep, or deer droppings, should be given once a week during the growing season. The plant is easily increased from cuttings of half-ripened shoots, dibbled in small pots filled with sandy soil and placed under a bell glass in the house where the parent plant is growing. When cultivated in pots, it should be trained as a pyramid, and the pendulous shoots be allowed to hang at will. After the flowers have faded, any necessary thinning of the shoots should take place, and new growth be encouraged for a couple of months, when the plant may be put out of doors for the purpose of ripening the wood. *J. Mayne, Bicton.*

BORONIA FASTIGIATA.

IN Western Australia this pretty little flowering shrub is said to become a bush 6 feet high. It is rarely seen in this country, and is of doubtful hardiness, so that its chief use is as small pot shrubs for the decoration of the cool house or conservatory. At the present time well-grown examples are in full flower. The four-petalled blooms are only a little over ½ inch across, but this is amply compensated for by their beauty and perfume. Nearly every shoot is terminated with erect cymes bearing eight or ten flowers, and lower on the leading shoots occasional axillary flowers are produced. The petals are rose-coloured, with curiously-haired anther filaments of the same colour, which are surmounted by deep yellow stamens. The leaves are small, obovate, somewhat coriaceous, and greyish in colour. As with all Boronias, great care in watering is necessary, and free ventilation should be given whenever possible. Being of a somewhat straggling habit, a little pinching of the leading shoots is of advantage, but, remembering that the bush is fastigiate, the stopping must be regulated so as to keep the plant open, or the shoots will become congested and either not flower or only do so sparsely. Boronia fastigiata responds to the treatment usually given other species of Boronia, but unless the peat used is of good quality, it should be dispensed with. *A. C. B.*

COREOPSIS GRANTII.

ACCORDING to the *Index Kewensis*, over 100 species of the genus Coreopsis have been described. By far the greater number of these are natives of the American continent. Of the remainder, a dozen or more inhabit tropical Africa, the subject of this note being one. C. Grantii was first collected during the Speke and Grant expedition, 1860-3, in the district of Karagué, German East Africa. To Mr. Morley T. Dawe, Director of the Scientific and Forestry Department, Uganda, we are indebted for its introduction into our gardens. In the spring of 1905 he forwarded seeds of it to Kew, collected at Buddu, in Uganda, where he says it flowers in December. Under cultivation the plants open a few flowers in mid-winter, but it is from the middle of February onwards that C. Grantii flowers so freely. During the summer of 1905, most of the seedlings raised were planted in a warm sheltered border outside the Water-Lily house; they failed to flower, however, before the plants were cut down by frost. Fortunately, two or three plants were kept in a cool greenhouse, where the first flowers opened early in 1906. A spray from one of these plants is figured in the *Gardeners' Chronicle*, Vol. xxxix., p. 162. It is also figured in the *Botanical Magazine*, tab. 8110.

Under cultivation the plants at present average 1 to 2 feet in height. The habit is low and bushy, the branches being semi-spreading. There is considerable variation in the size and lobing of the leaves, which are bipinnate, 2 inches to 6 inches in length, and the lower pair of leaflets 1 inch to 5 inches broad. The flowers of the seedlings raised vary a good deal in size, one especially having much larger flower-heads than the others; bright yellow in colour, they average 2 inches in diameter. The flower-heads are freely produced, and a succession is kept up for from three to four months.

The cultivation of the plants is very easy. As previously mentioned, the original plants were raised from seeds, but, so far as I am aware, despite repeated efforts, no seeds have so far ripened in this country. It is, however, readily increased by cuttings, which can be obtained from the plants cut back after flowering. These root readily in a close frame, with a little bottom heat in April or May. When rooted and potted off singly, they make rapid growth. As soon as the plants are established in the flowering pots, 5-inch or 6-inch, according to the time of rooting, they may be stood outside. This will be about the end of July. Early in September, or a little later if the weather is favourable, place the plants in a house where the minimum night temperature is not less than 50° F. Weak doses of manure water may be given at intervals. The plants will commence to flower about Christmas, or early in the New Year. The plants thrive in a compost of three parts fibrous loam, one part leaf-mould and sufficient coarse sand to make the whole porous. C. Grantii in habit would be termed a greenhouse shrub or sub-shrub. Why this plant failed to obtain notice from the R.H.S. Floral Committee at the meeting on March 3 last I do not understand. Were they to grow the plant, I make bold to say the majority would wish to award it a First-Class Certificate. *D. D.*

STREPTOSOLEN JAMESONII.

THIS plant is now one of the most showy species in the greenhouse. Owing to its orange-yellow-coloured flowers, it is much appreciated at this dull season, and specimen plants measuring 5 or 6 feet in height can be cultivated in two

years. Cuttings may be inserted at the present time, and if grown on liberally during the summer they will make such specimens by this time next year as will be capable of affording a mass of flowers. As soon as the cuttings have made roots, they should be potted and re-potted as they require more rooting space, and in June should be plunged in a position out of doors, leaving them there until October or such time as it is feared frosts may occur. The plants may be trained as pyramids, standards, or as climbers against a wall or up the rafters of a roof. As the flowers are pendant, they show effectively from these positions.

CLIANTHUS MAGNIFICUS.

This plant is now in flower on the roof of a greenhouse in these gardens, where its brilliant crimson flowers are very effective. In growth it is somewhat similar to Streptosolen, and may be given the same kind of cultivation.

ABUTILON VEXILLARIUM.

Like most of the species of Abutilon, A. vexillarium makes an excellent pillar or roof plant. It has green and yellow leaves and distinct, curiously-shaped flowers.

MANDEVILLA SUAVEOLENS.

This old-fashioned climbing plant still ranks as one of the best. It flowers very freely, and the flowers are white and fragrant. The shoots should be trained and tied regularly during the time the plant is making its growth, and syringing should be performed frequently, as the species is very liable to attacks of red spider. At Leonardslee this pleasing species is cultivated on a wall out of doors, facing to the south, where it yields a succession of flowers to those produced in the greenhouse. The plants should be pruned severely each season before they commence to grow.

TRACHELOSPERMUM JASMINOIDES.

As a roof or pillar plant this species is well known in gardens. It has evergreen foliage, and small, white, fragrant flowers. The plants flower during May and June. The species succeeds in a warm corner out of doors at Leonardslee. *W. A. Cook, Leonardslee Gardens, Horsham, Sussex.*

[Our correspondent sent good specimens of each of the species mentioned above.—Ed.]

A LATE APPLE CROP.

At fig. 107 is illustrated an Apple tree, the fruits of which were still ungathered on January 1. By the time the new year arrives most Apples have been removed from the store-room and consumed, and it is not often that they can be gathered in January on the trees, although we have known stray fruits of such late-ripening kinds as French Crab and Northern Greening to be found hanging as late as February. For the opportunity of figuring the example, we are indebted to Mr. Frederick Bedford, Straffan House Gardens, Co. Kildare, who writes: "The photograph of the Apple tree was taken by Mr. Robert Lindsey, Straffan, on New Year's Day. The variety is the French Pomme de Fer (Iron Apple), and the crop of one bushel was gathered on the day the photograph was taken, after having withstood the heavy autumn gales and early winter frosts, not a single fruit having been blown off. The fruits hung with tenacity even so late as the date of their gathering. The variety is a desirable one for culinary purposes, and is in season from April to the end of June, being then as fresh and brisk in flavour as fruits of other varieties gathered in December. Although French Crab is by some growers considered synonymous with Northern Greening, there is no resemblance between the two fruits."

TREES AND SHRUBS.

PICRASMA QUASSIOIDES (P. AILANTHOIDES).

A tree belonging to the Simarubaceæ, of which but little is as yet known in this country, though it promises to form a distinct and desirable acquisition, is Picrasma quassioides. The species has a wide distribution over Eastern Asia, for it has been found in Japan, China, the Himalaya, and even as far south as Java. The plants in cultivation have come from North Japan, and have proved to be quite hardy. It is probable that the specific limitations of Picrasma quassioides are at present too widely extended, and that the forms from Java and other southern habitats may prove to be distinct. It is scarcely credible, at any rate, that a Javan plant could survive our winters without protection. In the forests of Japan, Picrasma quassioides is a slender tree 20 to 30 feet high, with a trunk about 3 feet in girth. Its habit is rather thin, and this is especially noticeable when the tree is leafless. The leaves are pinnate and of a dark, lustrous green. In a young state the most attractive feature of the tree is the bark.

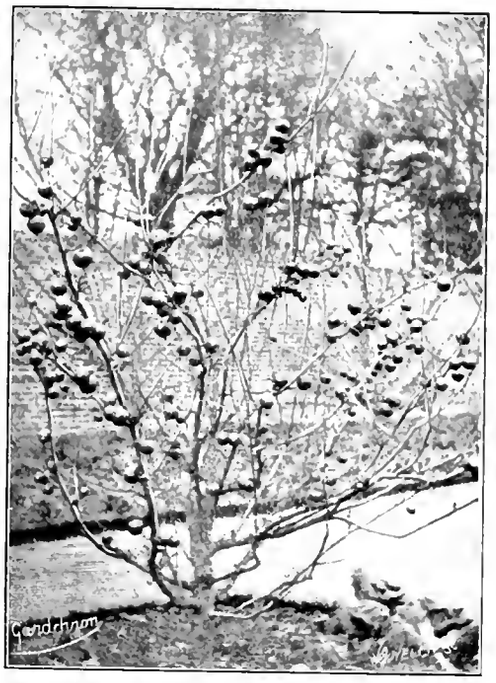

Fig. 107.—A crop of apples in Straffan House Gardens, Co. Kildare, as it appeared on New Year's Day.

This is of a reddish-brown, handsomely marked with yellowish lenticels. But in Japan its greatest beauty is in the autumn-colouring of its leaves; these turn first from green to orange, and then to deep scarlet. Sargent observes that "few Japanese plants I saw are as beautiful in the autumn as this small tree." There is a healthy young tree growing on the lawn near the Cactus house at Kew. This is about 12 feet high, and has flowered and produced seed from which young plants have been raised. The leaves have turned yellow before falling, but, up to the present, have not acquired the scarlet tinge. This tree belongs to the same family as the Ailanthus and is permeated by a singularly bitter principle. *W. J. B.*

THE ALPINE GARDEN.

HELONIOPSIS JAPONICA.

Although not entirely new to cultivation, this attractive Japanese Liliaceous plant was little known till the last year or two, when importations of it have been received from Yokohama under the erroneous name of H. breviscapa. H. japonica was first brought home by Mr. Maries, and plants flowered with Messrs. Veitch in March of the year 1881. It flowered at Kew in 1887, and was figured at the time in the *Botanical Magazine*, t. 6986. Judging from herbarium specimens, it appears to be a somewhat variable plant, and two species of the genus are recorded from Japan; while a third is found in Formosa. They are all, however, connected by intermediate varieties, and may well be extreme forms of one species. H. japonica, which is now in flower in the Alpine house, forms a tuft of strap-shaped leaves, each about 4 inches or more long, and from ½ to 1 inch wide. When young they are green, but assume a bronzy appearance with age. The stout scape, furnished with leafy bracts, is from 4 inches to 6 inches high, and bears from six to ten flowers, disposed in a very short raceme, or almost an umbel. When fully expanded the flowers are over an inch in diameter, and rich rose-purple in colour, set off by the spreading violet purple stamens, which are longer than the segments of the flower. This plant has a wide distribution in Japan, and is found at altitudes varying from 2,000 to 7,000 feet. H. breviscapa (often wrongly spelt "breviscarpa") is very similar in habit, but has smaller, white flowers, with blunter segments. It was exhibited by Messrs. Barr and Son at the Royal Horticultural Society's show in March, 1905, and obtained an Award of Merit (see fig. and description in *Gard. Chron.*, March 25, 1905). H. umbellata, the Formosan species, is not in cultivation, but does not appear to be distinct from H. japonica. *W. I.*

The Week's Work.

FRUITS UNDER GLASS.

By T. Coomber, Gardener to Lord Llangattock, The Hendre, Monmouthshire.

Late vines.—Vines in the late houses having started into growth, a genial atmosphere must be maintained by syringing the vines in the morning and afternoon, and by damping the surfaces of the house on fine days as often as necessary. The atmospheric temperature at night should be 50° to 55°, and by day 60°, allowing the heat to increase under the influence of sunshine and in the presence of liberal ventilation. Disbudding may be commenced by rubbing out the weak and otherwise unsatisfactory growths, leaving a very liberal number of the strongest shoots until it can be seen which shoots will be capable of producing the strongest inflorescences. Stop the shoots at two or more leaves beyond the flowers, according to the amount of space available for foliage, and after they have become sufficiently strong draw them down very gradually to the trellis. When this stage has been reached the vines will require liberal supplies of liquid manure or top-dressings of some quick-acting artificial fertiliser. Out-of-door borders are always too wet at this season of the year for liquid manures to be applied, therefore make applications of an artificial manure in showery weather, and later in the season afford the border a light mulching of short stable litter.

Late Hamburgh house.—This description of vinery is more often employed by amateur gardeners than any other. The vines have usually indoor borders only, and these are frequently allowed to suffer from lack of moisture and plant food. If such houses were not closed until the vines commenced to push their growths, they will now require similar treatment to that recommended for the late vines.

Cucumbers.—Plants which were raised early in the year should be lightly cropped, and the fruits should be gathered directly they are ready for consumption if it is desired to keep the

plants in a fruiting condition for a considerable period. Apply frequent supplies of liquid manure in a tepid state to the roots, and also occasional top-dressings. Maintain a heat during the night of 70°, and afford a little ventilation during the day when the sun-heat has caused the thermometer to register 80°. Syringe the plants and the surface of the beds early in the morning and again in the afternoon at the time of closing. Thin out any weak shoots and remove any damaged foliage, stopping the other shoots at one leaf beyond the fruit, it being essential to prevent overcrowding of the foliage.

Cherries.—If the trees have not been hurried during the process of flowering, they may now be considered to have passed a critical period. Care will still be needed until the fruits have formed stones. No more fire heat should be employed than is necessary to maintain the atmospheric temperature at night to 45 degrees, which may be increased during the day to 50 degrees. As soon as 50 degrees is reached, afford a little ventilation. Increase this on sunny days so that 65 degrees may not be exceeded. In the afternoon, as the sun loses its power, reduce the ventilation, and close the house moderately early. Syringe the trees, morning and afternoon, on bright days, and take care that the soil, whether in pots or borders, is not allowed to become dry. Applications of carefully diluted manure water may be given the roots occasionally. Stop the shoots of fully-developed trees at the third or fourth leaf to promote the formation of fruit buds, but in the case of young trees of any description, suitably placed shoots will be needed for purposes of extension.

THE HARDY FRUIT GARDEN.

By F. Jordan, Gardener to The Dowager Lady Nunburnholme, Warter Priory, Yorkshire.

Disbudding and thinning.—Apricot, Peach, and Nectarine trees are later than they have been for several seasons past, but they will now need to be examined every day. Apricots are the first to need attention in the matter of disbudding, but they do not require to be disbudded so severely as the Peach. Commence as soon as the shoots can be rubbed off by means of the thumb and finger, beginning at the top of the tree and gradually working downwards to the base. Remove all the shoots that are in undesirable positions, such as those that grow from the extreme back or from the front of the tree. Encourage the formation of natural spurs whenever possible, and also artificial ones by pinching such shoots as are not required for extension. It is better to do a little disbudding and thinning at one time, repeating the operation at frequent intervals, until the work is finished, than to cause a check to the trees by removing much growth at one time. The cultivator should study the peculiarities and habits of each kind of tree and endeavour to disbud and pinch in such a manner as to render it necessary only to use the knife in winter to a limited extent. Train in young shoots near to the base of all the spurs and branches that are likely to become useless, and will have to be cut out at a future time. Many old trees are thickly studded with fruit spurs, and therefore often set their fruits in clusters. It will be necessary to thin out such fruits and any others which would be likely to get crushed, as soon as it can be seen which will swell best. Do not, however, thin the fruits severely at the first operation, but remember that many may fall during the "stoning" process. The protective material should be removed from the trees whenever the weather is mild, but it should be kept in a position where it will be available for use when required.

Grafts.—Freshly-grafted trees should be examined and any cracks that are found in the clay encircling the grafts be made good by moistening the clay and rubbing portions of it into the cracks; a little damp moss if tied into position over the clay and frequently moistened will serve to prevent further cracking. One or two shoots may be allowed to grow from the stocks below the point at which the graft is inserted for a short time only to encourage the sap to circulate; all others may be removed at once. If any grafting remains to be done it should be pushed forward to completion. Fruit trees or stocks that were grafted last year should be examined and the grafts made secure from winds by the affording of stakes and ties.

Raspberries.—Canes planted in autumn and spring that were cut down to the ground level, as advised in a previous Calendar, will now be producing many suckers from the base. Do not allow any but the strongest of these to remain. Remove any suckers that may appear above the surface of the soil between the rows of old plantations and any weak growths that appear in the rows themselves. This should be done carefully with a fork, and the ground should be made firm afterwards by treading.

THE KITCHEN GARDEN.

By J. Beckett, Gardener to the Hon. Vicary Gibbs, Aldenham House, Elstree, Hertfordshire.

Beetroot.—The Globe or Egyptian variety raised from seeds that were sown on a mild hot-bed in frames are now making active growth and should be thinned sufficiently to allow the plants to develop without becoming drawn, but the final thinning can be done after the roots have become as large as a good-sized Radish; the thinnings may then be used for salads. Keep the surface soil frequently stirred and admit plenty of ventilation during favourable weather. Make a liberal sowing of the same variety on a south border out of doors; the produce will be found to be much more serviceable during summer than the longer rooted kinds. The main sowings should not be made until the end of the present month or the beginning of May. Roots of small to medium size are most desirable.

Globe Artichokes.—Although these have been protected in these gardens, they have fared badly during winter, and we shall have to depend to a large extent on suckers which were removed from the plants last autumn and have been wintered in cold frames. There will be no further need for the protective material, and if this has not been already removed, it may be taken away at once. After this has been done, apply a good dressing of short manure and let it be forked into the soil, leaving the plantation in as tidy a condition as possible. Plants at present in pots should be planted out into deeply trenched and heavily manured ground, applying plenty of finely sifted cinder ashes round the base of each plant.

Parsley.—A constant supply of Parsley throughout the year can only be assured by making frequent small sowings from early in spring until late in summer. I have found that the best results during summer can be obtained by making at least two sowings in boxes in spring, raising the plants in heat, thoroughly hardening them off and pricking them out whilst still quite small into deeply tilled rich land, which should be made very firm. They are planted in rows, placed 1 foot apart, and the plants are placed at the same distance in the row. April and May are the two best months for the planting, and almost any situation in the kitchen garden is suitable. Frequent applications of soot are very beneficial to Parsley. It is advisable to take great care in selecting the best varieties for cultivation.

Spring Cabbages.—Many complaints have reached me from various parts of the country as to the unsatisfactory condition of these plants, due probably in a great measure to the excessive wet in autumn, and also to several short periods of severe frosts. Unless the stems are well protected they are insufficiently matured to withstand such weather. It is very necessary in the early part of November to draw the soil well up to the stems of these plants, much in the same manner as Potatos are earthed up. I never remember to have seen our Cabbage plants in better condition than they are this season. The frequent use of the draw-hoe at this season is the greatest stimulant to growth that can be applied to this crop.

Turnips.—Make another sowing of the variety Early Milan on a south border. Apply a liberal dusting of soot, and afford the seeds protection against birds.

Summer Spinach.—Make frequent sowings of this vegetable between the rows of Peas.

Chicory and Sorrel.—Make two sowings of Chicory, one at the present time, and another at the beginning of May. Seeds of Sorrel should also be sown at the present time.

PLANTS UNDER GLASS.

By Thomas Lunt, Gardener to A. Stirling, Esq., Keir, Perthshire, N.B.

Hard-wooded plants.—Such species as are suitable for growing into large specimens, including Eriostemon pulchellus, E. densifolius, E. buxifolius, Polygala oppositifolia, P. Dalmaisiana, Boronia tetrandra, Tremandras, Darwinia, Hookeriana (Genetyllis Fuchsioides) and D. macrostegia (tulipifera) should now be examined for the purpose of determining which of them needs to be repotted. Many of these plants obtain a firm hold of the sides of the pots with their roots, and it is therefore advisable to break the pot before turning the plant out. Let the ball of soil be pricked up slightly by means of a sharp-pointed stick, doing this with great care and only sufficiently to loosen the points of the roots. The roots of the plants should be brought into a medium state of moisture before repotting is attempted. Let the pots be provided with sufficient drainage, and, if possible, select such pots as are made of soft and, therefore, porous material. The plants should be shifted into pots only sufficiently large to allow of 1 inch of fresh soil being placed round the roots. In the process of potting add only a little soil at one time and ram this very firmly together with the potting stick. Any stakes that need to be removed and others substituted should be given attention before the plant is potted. If the side stakes have to be removed the plants should be securely tied to three stakes placed in the form of a triangle into the old ball of soil before commencing to take it out of the old pot. This will prevent the plant getting loosened at the neck just above the surface of the soil, for if once a plant of this nature becomes loosened at this point it never thrives afterwards. A suitable compost for use in potting is one consisting of peat, silver sand, and a few small bits of charcoal. The strictest attention should be given to the matter of affording water, this being the most essential point in the cultivation of these plants. For forming specimens very careful training is necessary; the stronger shoots should be securely tied down, and all the weak ones left in as upright a position as possible. This will prevent the need for cutting back the strong growths, and the plant will become furnished with shoots in a shorter period. The best position for the plants is one exposed to the light in an ordinary greenhouse. In no circumstances must they be crowded. Liberal ventilation should be afforded whenever the nature of the weather will allow.

Diosma ericoides.—This species may be treated in a similar manner to that I have already described, if it is required for flowering, but the green, sweet-scented shoots if arranged amongst cut flowers at this period are very agreeable. When potting this plant add a little loam to the compost already described, and do not pot quite so firmly as in the case of the other species.

Seedling Primulas.—These will now be ready for pricking off into small thumb pots, filled with a compost of loam, leaf-mould, and sand in equal parts. Place the plants in a position near to the glass in a house or frame of intermediate temperature, and afford shade from bright sunshine.

THE ORCHID HOUSES.

By H. G. Alexander, Orchid Grower to Major G. L. Holford, C.V.O., C.I.E., Westonbirt, Gloucestershire.

Cattleya citrina.—This remarkable species, which is commonly known as the Mexican Tulip, is just now opening its fleshy, yellow flowers, which yield a delicate odour. The peculiar habit of this species necessitates the plant being suspended head downwards, as in no other position can it be induced to grow. The plant should be fastened on rough blocks of wood or teak-wood rafts, the latter being preferable, as a little sphagnum-moss can then be packed between the bars, which helps to conserve the moisture about the roots. Abundance of water should be afforded until after the flowering season, and this should be given by dipping the plants in a pail of water. After flowering it is only necessary to afford enough to prevent the pseudo-bulbs shrivelling. Most Cattleyas grow during the spring and summer, but this practice is quite reversed in the case of Cattleya citrina;

but it is not difficult to keep the plants resting if a light and well-ventilated position in the cool intermediate house be chosen for them.

Zygopetalums. The hybrids, Z. Sanderi, Z. Perrenoudii, Z. crinito-Gautieri, and others, which produce their flower spikes simultaneously with the young growths, are all very attractive for flowering during the spring months. Soon after the flower spikes have been removed, attention should be paid to the repotting of any plants that need this operation, as from the base of the new growths young roots are produced at an early stage. These plants have a great dislike to root-disturbance, therefore should not be shifted unless the rooting material is in an unsatisfactory condition. The directions as to compost, position, watering, &c., given in an earlier Calendar for species of this genus, will meet the requirements of the hybrids.

fifth, with plenty of crushed crocks and charcoal and silver sand added, constitutes a suitable rooting medium. Use the materials in as rough a state as possible, and provide the pots with plenty of drainage, so that the large quantities of water required during the growing season will not render the material sour.

THE APIARY.

By Chloris.

Feeding.—There is more need than usual for feeding, and the conditions in some cases are extreme. This is not surprising, when the weather of last year is considered and the poor crop of honey that was secured. Those who were prudent fed liberally last autumn, and they are now reaping the reward, for such colonies are

each side. Some advocate the use of the spur, but, generally speaking, it is not needful, and its careless use leads to the foundation being cut across. The whole of the frames in one hive that I examined had been rendered useless by the foundation being cut in the manner named.

Preparing supers.—Too much stress cannot be laid upon having all shallow frames and sections ready to put on when the right time comes. As with brood frames, so with shallow frames, they ought to be wired so that they will withstand the rotary motion of the extractor. There is only one exception to the wiring, and that is where the source of the honey supply is heather, and in this case the honey is usually pressed out, as the extractor is often useless for the purpose. In such cases wiring would be a hindrance rather than a help. If new frames have to be purchased, the broad-

Fig. 108.—Flowering specimen of Ada aurantiaca from Major Holford's collection. Awarded a cultural commendation at the meeting of the Royal Horticultural Society held on March 31 last.

Ada aurantiaca (see fig. 108).—This showy species is amongst the most beautiful of spring-flowering Orchids, and especially when well-flowered specimens are seen. Cool house treatment is usually recommended for these plants, but my experience is that a rather warmer temperature, especially during the winter, gives better results. We grow them in the cool intermediate house, and they are shaded from strong sunlight during the hottest part of the year. Plants that have passed out of flower, if in need of fresh rooting material, may be given attention, as new roots soon push forth from the last-made growths. A compost consisting of lumpy peat two-fifths, fibrous loam two-fifths, and sphagnum-moss one-

in a safe condition and well able to look after themselves. Syrup should be supplied wherever there is need, care being taken not to spill any, and not to cause any unnecessary loss of heat.

Fitting up brood frames.—It is necessary, about every third or fourth year, to renew the foundation in the brood frames, for the cells become smaller each time brood is hatched in them, because the thin skin of the chrysalis is left behind. If economy is necessary, then thinner foundation may be used up to 10 sheets to the pound if the frames be wired. There are many ways of wiring, but four strands horizontally placed is one of the simplest, allowing the foundation to have the strands alternately on

shouldered class are well worthy of a trial, for they enable us to do without the broad metal ends. The sections should all be fitted with full sheets of foundation. Remember, too, that when you are preparing them, that you set to work first to wet all the joints with hot water to render them supple, and when you have wet the number required, turn the pile over and thus fold those first wetted. By following this plan, many disasters in folding will be averted.

Water.—When bees are raising large quantities of brood, it is necessary to provide water for the bees if there is no natural supply near the hives. If water be placed in any shallow vessels containing stones, with their surfaces out of the water, the bees will be able to make use of it

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, APRIL 20—*Easter Monday.* Bank Holiday.

TUESDAY, APRIL 21—
Huntingdonshire Daffodil and Spring Fl. Soc. Sh. at Huntingdon. Devon Daffodil and Spring Fl. Sh. at Plymouth (2 days).

WEDNESDAY, APRIL 22—
Roy. Bot. Soc. Exh. at Regent's Park.

THURSDAY, APRIL 23—
Midland Daffodil Soc. Sh. at Bot. Gardens, Birmingham (2 days).

SATURDAY, APRIL 25—
Quinquennial Exh. of the Soc. Roy. d'Agri. et de Botanique de Gand at Ghent, Belgium, lasting until May 2.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich - 48.5°.

ACTUAL TEMPERATURES.—
LONDON.—*Tuesday, April 11* (6 P.M.): Max. 48°; Min. 37°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Wednesday, April 15* (10 A.M.): Bar. 30.1; Temp. 43°; *Weather*—Sunshine.
PROVINCES.—*Tuesday, April 11* (6 P.M.): Max. 48° Ireland S.; Min. 44° Lancaster.

SALES FOR THE ENSUING WEEK.

WEDNESDAY—
Herbaceous and Border Plants, Liliums and Hardy Bulbs, at 12; 600 Roses at 1.30; Palms and Plants, Azaleas, &c., at 4, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

FRIDAY—
Liliums, Hardy Plants and Bulbs, Gladiolus, Greenhouse Plants, Ferns, at 12, Imported and Established Orchids, at 12.45, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

***Trees.** Several works have recently appeared on the trees of this country, but in spite of this, it cannot be said that anyone since Loudon's time had really got at close quarters with the subject until the authors of the present work set about their task. The publication of *The Trees of Great Britain and Ireland*, by Messrs. Elwes and Henry, therefore marks an era in the history of the tree-lore of these islands.

It is true that the limits of the work are somewhat circumscribed. The authors only profess to concern themselves with such trees, native and foreign, as can be considered to be of timber-producing size. So that in comparison with the whole extent of woody vegetation hardy in the British Isles, or even with that portion genuinely arborescent, the scope of the work is, to a certain degree, restricted. But the group with which the authors deal is not only the most important one from an economic point of view, but it is in many ways the most interesting.

* *The Trees of Great Britain and Ireland*, by Henry John Elwes and Augustine Henry. Privately printed.

Messrs. Elwes and Henry have treated their subject from two points of view—the botanical and the practical. First there is the botanical aspect. This consists of a general discussion of the genus, a description of its botanical characters, its limitations and relationships, and its geographical distribution. This is followed by a synoptic key to the species. In these keys we note a feature of peculiar value: they are based almost wholly on vegetative as distinct from reproductive characters. Every cultivator of large-growing trees, especially those of exotic origin, knows that a large proportion of them rarely or never flower and fruit. This is especially true of young trees. A means of "running them down," and identifying them in the absence of flower or fruit and on leaf and stem characters alone, is, therefore, particularly useful. After the key comes a detailed description of the individual species and an account of its varieties and hybrids—if such exist. All this is written in language that is scientific yet intelligible to men of ordinary education. For this, the botanical side of the subject, Dr. Henry appears to be largely responsible. It is only those possessed of some knowledge of the difficulties and pitfalls that hamper the student of this branch of the subject who can fully appreciate the labour, research, and critical acumen that is shown in its elucidation.

The practical and perhaps more popular side of the subject is the work of Mr. Elwes. This deals with the introduction to this country of individual species, their behaviour under cultivation and under various climatic conditions, the value of their timber and the uses to which it can be put, the diseases by which they are attacked, and other cognate matters. A feature of singular interest is an account of the remarkable trees in the British Isles, giving their history (when known) and descriptive notes as to form, height, girth of trunk, &c. The gathering together of these statistics must have entailed much labour, but their historical interest and their value for purposes of comparison in future years are such as to make it well spent. It is well known that both the authors have travelled greatly. Possessing, therefore, the great advantage of having studied in their wild state nearly all the trees dealt with in this work, and having besides visited every notable arboretum and forest in the British Isles, they have been able to invest their subject with much interest and even fascination.

Having written in general terms of the works as a whole, we may turn in particular to the volume which has just been published. In the quality of both its illustrations and letterpress it marks, if anything, an advance on its two predecessors. In all the volumes the beauty of the pictures has been remarkable. They are admirable reproductions of photographs, some of which depict the trees as growing wild. Most of them, however, have been made from specimens or groups of trees existing in the British Isles, which are described in the text. The Cedars lend themselves peculiarly well to artistic treatment, and in this third volume there is a fine series of illustrations of that genus. We see, for instance, the Lebanon Cedar as it occurs wild on its native site, as well as typical flat-branched specimens of magnificent spread and girth of trunk such as are to be found at Blenheim, Painshill, Goodwood, and other places; we also see other specimens more remarkable for their lofty stature as they are to be observed at Strathfieldsaye and Petworth. The famous Cedar Avenue at Dropmore is well presented, whilst pictures of the Atlas Cedar and the Deodar are also given. There is likewise a series of illustrations of the Scotch Pine of perhaps even greater artistic merit. We have never seen any tree-portraits, produced by a mechanical process, more charming than the "Scots Pine Avenue at Carclew," or the "Scots Pine at Loch Morlich." But whilst such pictures as these will probably attract the ordinary lover of trees, the specialist will turn to the illustrations of trees of greater rarity, even though they may be less picturesque. Of these there is a rich assortment, amongst which are the magnificent Gymnocladus and Sassafras, at Claremont, the fine Cunninghamia at Bagshot Park, the Nyssa at Strathfieldsaye, Fagus Cunninghamii at Fota and F. betuloides at Bicton, Carya amara at Bute House and C. alba at Brocklesby Park.

To supplement the descriptive work by Dr. Henry, there are engravings to illustrate in outline the leaves of many of the species mentioned in this volume, exhibiting their characteristic venation, hairiness and margins. The buds and young bark are also shown. These diagrams will be of considerable assistance for the purposes of identification.

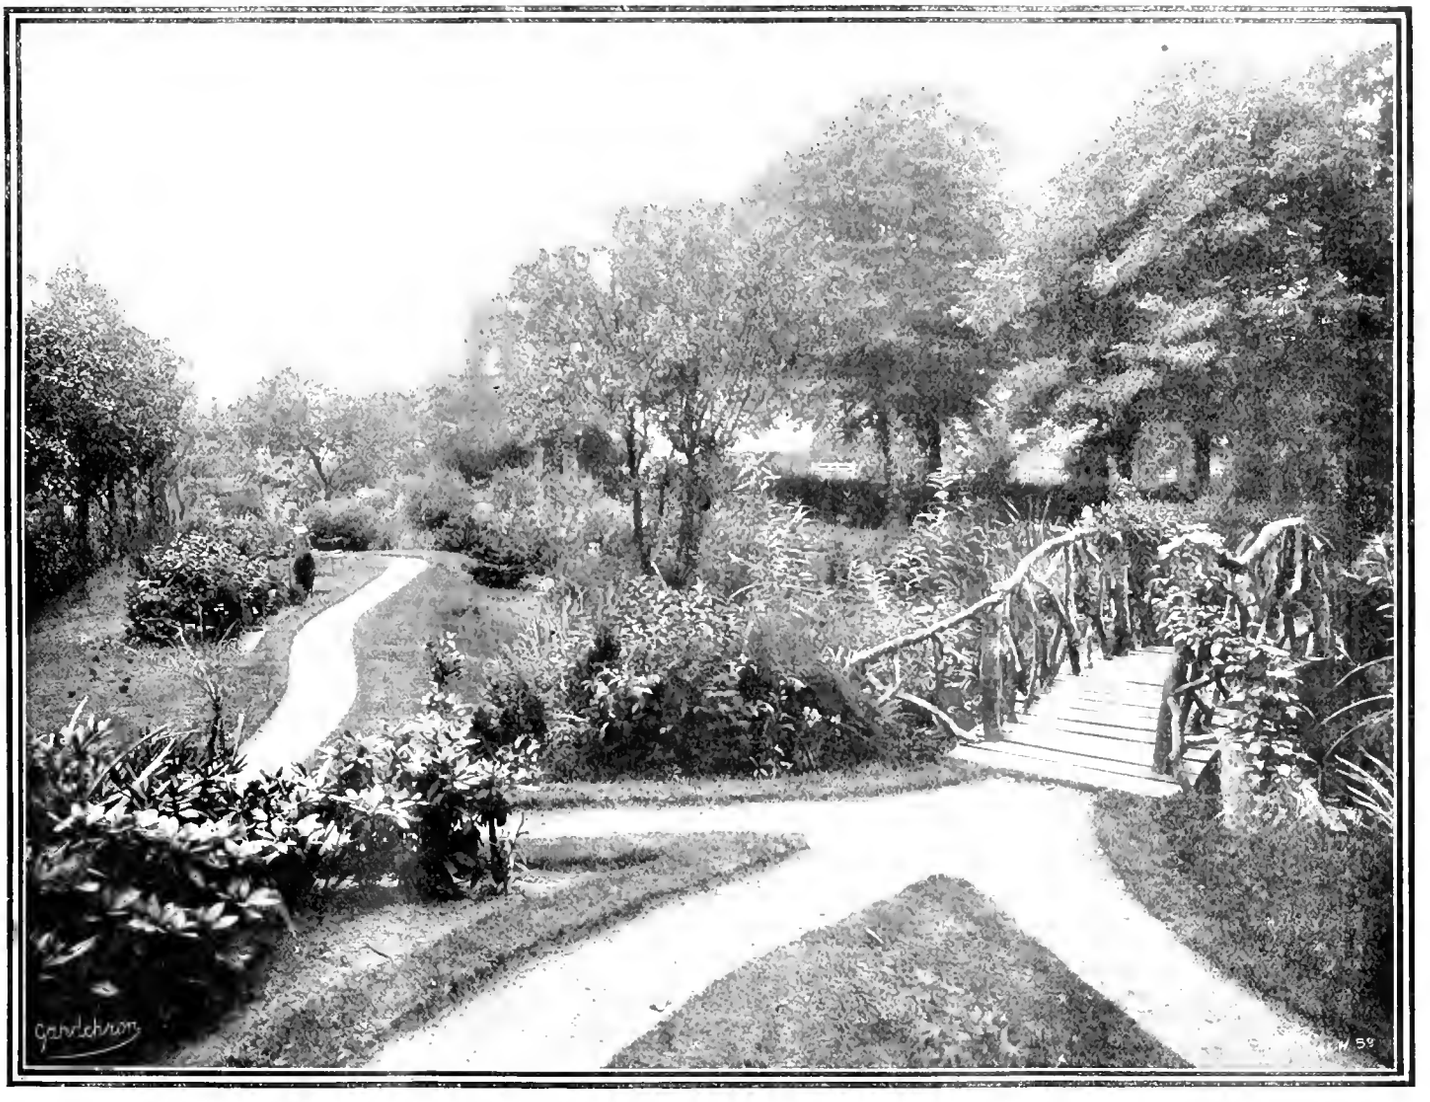
From what we have said as regards the illustrations, it will have been gathered that this third volume deals with many trees of special interest. Concerning the Cedar of Lebanon Mr. Elwes has written an interesting and instructive account extending over more than a dozen pages. The old and vexed question as to the specific distinction of the three Cedars is discussed; but not only are they here given the specific rank often accorded them, but they are joined by a fourth, the Cyprus Cedar, hitherto known as C. Libani var. brevifolia, which is here elevated to a species. Not many however will in these days, we think, subscribe to the opinion here expressed that there are better reasons for uniting C. atlantica and C. Deodara as one species than there are for uniting C. atlantica and C. Libani.

Blume's genus, Nothofagus, is revived for the Beeches of the southern hemisphere, with, as it seems to us, very good reason. English arboriculture is indebted to Mr. Elwes for the recent reintroduction of some of the South American species to this country, and he has here an interesting story to tell about them, based on his recent visit to that Continent. The pages devoted to the Hornbeams and Hop Hornbeams are useful and interesting, as also are those in which the stately and beautiful members of the genus Arbutus are described. An admirable and exhaustive account of the Scotch Pine occupies nearly thirty pages. Many of the world's most remarkable and interesting trees belong to genera containing but one or only a few species, and they naturally represent the most distinct and unusual types. In this volume several species belonging to such genera are dealt with. Among them we have Cunninghamia, Liquidambar, Sassafras and Sciado-

pitys; and the story of the two Sequoias—the mammoth trees of California—is told once again. The largest and most diverse genus dealt with is Acer. A synopsis is given of all the cultivated species (which now amount to between fifty and sixty), whilst fifteen of the larger timber-producing Maples such as the Sycamore, Norway Maple, and Sugar Maple are reviewed in detail.

The absence of any system in the arrangement of the genera dealt with in this work has been adversely criticised. There are only two arrangements that are available: the Natural Orders and genera might have followed each other according to their assumed natural relationship (as they do in Loudon), or they might have been arranged alphabetically. Both these methods are usually found to be difficult in practice. Whilst the order of relationship adopted in this country is commonly based on Bentham and Hooker's *Genera Plantarum*, whilst the Americans and Germans follow a totally different sequence, and indeed, whatever "natural" system the authors might have adopted, it would probably have been of little service to nine-tenths of the students of such a work as this. The alphabetical plan, on the other hand, possesses one great advantage in enabling the general reader to find his subject quickly. This, however, assumes he knows the adopted name of the genus he is in quest of. In such a work as that before us most people would scarcely think of looking under the letter "N" for the Antarctic Beeches, and many would expect to find "Sassafras" under "Laurus." Then the alphabetical arrangement usually implies either keeping back the publication of the work until it is completed, or else the addition of omitted matter in the troublesome form of an appendix. On the whole, then, we do not consider that the haphazard arrangement of the subject-matter need give serious ground for complaint, provided that a full and careful index is given.

It would, however, have been desirable to have kept all the species of one genus together. Whilst the Corsican Pine appears in the second volume and the Scotch Pine in the third, the rest of the genus Pinus has yet to come; and the article on the Common Oak in the second volume is the only portion of the genus Quercus that has yet appeared.



[*The Garden* photo by H. N. King.

Fig. 109.—View in the "Japanese" garden at Rufford Abbey, Notts.

(See Supplementary Illustration, also fig. 110.)

Our Supplementary Illustration affords a view of the Roman garden at Rufford Abbey, Ollerton, Notts., the residence of Lord John Savile. This Roman garden was formed in 1904, and is approached by four stone-covered paths that lead to an old Venetian well-head in the centre. There are several arches and pergolas in the garden, and there is also a temple, built mainly of stone discovered in Roman excavations and brought to this country by the late Lord Savile. There are also two trees that have been planted by His Majesty King Edward VII., who has several times visited Rufford Abbey. Nearly opposite the garden under notice is another known as the Japanese garden (see fig. 109). This is also of recent construction, having been formed upon the site of an old orchard about five years ago. In it are four ponds that are connected by streams and fed by an artificial waterfall. The central pond contains an island, and all around are planted subjects of a water-loving nature, with Clematis and Roses entwined along the rustic bridge which affords access to the opposite bank. There are many handsome shrubs hereabouts; some are accommodated in beds cut in the grass lawns, others are planted singly, or interspersed in clumps near the water's edge. The waterfall is a very pretty scene, and near by is a tea-house, which forms a delightful and cool retreat in summer time, when it is set in a bower of beautiful flowers. There are many fine borders planted with hardy herbaceous plants, and at fig. 110 is given a view of a portion of one of these borders on the east front, the vase forming the boundary line. The Rufford gardens are under the care of Mr. J. Doe, and their condition is most praiseworthy.

BOTANICAL MAGAZINE.—The April number contains illustrations and descriptions of the following five plants, and the usual cultural notes are added under most of them:—

BULBOPHYLLUM BINNENDIJKII, tab. 8187.—This is a fine illustration of a remarkable plant, which almost suggests the form of an octopus with outspread tentacles. The plant originated from Java, and there has been some doubt as to its relation or identity with other species from the same island. A flowering specimen was shown under the name of B. Ericssonii by Messrs. SANDER & SONS, of St. Albans, at the Temple Show in 1907. It appears to be a difficult subject, and Mr. WATSON says that of the many specimens imported by the St. Albans firm, it is doubtful if a score are now alive.

KÆMPFERIA KIRKII, VAR. ELATIOR, tab. 8188.—This is a handsome plant, allied to Hedychium, and occurs in tropical Africa. The specimen from which the figure was drawn was presented by Mr. H. J. ELWES, of Colesborne, Cheltenham. The prevailing colour of the flower is pink.

SAXIFRAGA BRUNONIANA, tab. 8189.—This plant occurs in the Himalayas, at an elevation extending from 9,000 to 13,000 feet. Its flowers are yellow, borne on red stems, and it shares with a few other species the peculiarity of producing long red stolons, which bear vegetative shoots at their apices. These serve as propagative structures, readily becoming independent plants. This Saxifraga has proved hardy at Kew, but thrives best when cultivated in stony soil in a cold frame.

RHEUM INOPINATUM, tab. 8190.—It has been proposed to divide this genus into two groups one, the Monticolæ, with leafy stems and membranous leaves; the other, the Deserticolæ, possessing bare stems and firm leaves. The species figured belongs to the latter group. The seeds from which the specimen was raised were collected in Tibet, and sent to Kew in 1905. The plant is an attractive one, the grey-green leaves forming a good ground colour for the crimson inflorescence, which lasts for several weeks in good condition. It is quite hardy, and should prove a valuable plant for the border.

OLEARIA CILIATA, tab. 8191.—At first sight, the plant suggests a shrubby Aster, bearing lilac-coloured flower heads, rather than an Olearia. It forms a bush 1 to 2 feet high, the stems of which are covered with linear recurved leaves. The plant is a native of Western Australia, and seeds were sent to Kew by Sergt. Goadby, R.E. These were sown, and a bush flowered in the temperate house in April last year. The plant seems difficult to propagate, and has failed so far to set seeds.

MR. BURPEE.—Our American contemporary, *The Country Gentleman*, has recently published an account of Mr. W. ATLEE BURPEE, whose seeds, especially Sweet Peas, are known world-wide. Mr. BURPEE was born at Sheffield, New Brunswick, April 5, 1858, and at the age of 18 opened, in connection with Mr. G. S. BENSON, jun., a little store at 223, Church Street, Philadelphia, dealing chiefly in fancy pigeons and poultry. The firm lost $3,500 the first year, and was glad to take in a third partner. In April, 1878, Mr. BURPEE withdrew from the firm and started by himself as "W. Atlee Burpee & Co.," dealing in seeds as well as birds and dogs. The second year of the first partnership just paid expenses. "The third year, by myself," Mr. BURPEE says, "I netted a profit of $2,700. In 1882 the shop in Church Street was found to be too small for the increasing business, and the firm's present commodious premises were acquired." Mr. BURPEE is a life member of the Société Nationale d'Horticulture de France, and has been for some years vice-president of the National Sweet Pea Society of England. In 1893, in Chicago, he was elected president of the American Seed Trade Association, presiding at the next annual meeting at Toronto, and has been a director of the Wholesale Seedsmen's League since its foundation.

FLOWERS IN SEASON.—A flower of the curious and evil-smelling flower of Scoliopus Bigelowii has been sent us by Mr. W. A. COOK, gardener to Sir EDMUND LODER, Bart., Leonardslee, Horsham. The flowers are a dull greenish colour, with purple stripes. A plant of this species was figured in our issue for March 3, 1894, p. 267.

[*Photograph by H. N. King.*

FIG. 110.—BORDER OF HARDY HERBACEOUS PLANTS AT RUFFORD ABBEY.
(See Supplementary Illustration, also fig. 109.)

THE NATIONAL CHRYSANTHEMUM SOCIETY having again decided to hold three exhibitions, the dates are fixed for October 7, 8; November 4, 5, & 6; and December 2, 3. All these shows will be held at the Crystal Palace, Sydenham. At the exhibition on November 4, 5, & 6, interest will be centred, as usual, in the classes for Japanese blooms, and in the most important class, that for 48 blooms, a special prize of £5 5s. is offered by the late president, C. E. SHEA, Esq., in addition to a cup. An interesting class is the one for 24 blooms of Japanese varieties, six of which are to be of the last two season's introductions; the substantial sum of £12 is offered as the first prize. Sir ALBERT ROLLIT, the president, offers a prize of £5 5s. in the class for 24 Japanese blooms of distinct varieties. There are numerous classes for floral devices, and others are for fruits and vegetables. The income of the Society during 1907 shows an increase over that of the previous year, but this notwithstanding, it has been necessary to transfer £70 from deposit to general account. By the new rule members of the committee are eligible to act as judges at the Society's shows, but no fees will be paid them.

NATIONAL CARNATION AND PICOTEE SOCIETY (SOUTHERN SECTION).—The exhibition of this society, which is fixed for Wednesday, July 22, will again be held in the Royal Horticultural Hall, Vincent Square, Westminster. The schedule provides for 73 classes, of which four new ones are added to those for dressed flowers. The object of these additional classes is to encourage the cultivation of Bizarres, Flakes and white-ground Picotees, which have to some extent been somewhat neglected of late years. In the open class is offered the "CARTWRIGHT" Challenge Cup of the value of 20 guineas, and the Committee invite competition in this section by the trade growers. The schedule is mainly divided into four divisions, and in each of the first three of these the President, MARTIN R. SMITH, Esq., offers challenge cups to the winner of the highest aggregate number of points. Valuable information is included at the end of the schedule upon the standard of excellence in the florists' Carnation and Picotee, with a description of the various flowers, including Selfs, Fancies, Bizarres, and Flakes, and yellow and white-ground Picotees.

EDINBURGH CHRYSANTHEMUM EXHIBITION.—The annual exhibition of the Scottish Horticultural Association will be held on November 19, 20 & 21, in the Waverley Market. The prize money offered totals £450, the classes including several for fruits and vegetables. The most important class is that for 15 vases of Japanese Chrysanthemums. The first prize is the City of Edinburgh Cup and £20 in money. A challenge cup is also offered for eight vases of Japanese Chrysanthemums, but the competition is restricted to Scottish gardeners and amateurs.

THE NATIONAL AURICULA AND PRIMULA SOCIETY will hold their annual show in conjunction with the Royal Horticultural Society's fortnightly exhibition on Tuesday, April 28. Copies of the special prize schedule may be had on application to Mr. T. E. HENWOOD, Auricula Villa, Hamilton Road, Reading.

A GARDENER'S LONG SERVICE.—Mr. JOSEPH MALLENDER has retired from the post of gardener at Hodsock Priory, Worksop, after a period of 40 years' service. Mr. MALLENDER has made many friends at Blyth, and they have recently presented him with a marble timepiece, chair, and purse containing gold. In thanking the donors for their kindness, Mr MALLENDER said that during the 40 years he had been at Hodsock Priory he had been encouraged by generous employers. The MELLISH family had made him a happy man for the rest of his life, and only the previous day the Misses MELLISH gave him a gold watch as a keepsake.

RUBBER EXHIBITION IN LONDON.—The proposals to hold a rubber exhibition this year have met with such ready response on the part of the planters and rubber manufacturers, as well as from the governments of rubber-producing countries, that an arrangement has been made for an exhibition to be held in the R.H.S. Hall, Vincent Square, from September 21, 26. A preliminary prospectus has been issued, and it is evident that the show will be one of considerable interest. The whole art of rubber-collecting and manufacture is to be illustrated, and there will be addresses and lectures on the various processes which will serve to explain the various matters connected with the industry.

THE CULTIVATION OF CAPSICUMS IN ROUMANIA.—Of Capsicum annuum (Paprika) there are several varieties having pods of various sizes, some large, others small, sweet, slightly hot in the mouth, and others very pungent. In the Balkan lands, the seeds are sown on hotbeds in March to allow of a long season for developing the crop. When there is no longer any danger from frosts, the plants are set out in light soil in warm positions, and, with the exception of abundant applications of water and hoeing, they get no special attention. In those countries, and so far north as Hungary, Capsicums, like the Egg plant (Solanum Melongena) and Mallow (Hibiscus esculentus) are reckoned among the principal vegetables. The large-fruited, thick-fleshed Capsicum fruits are, whilst still green, roasted on the hot plate of the close cooking stove, freed from the rind, and eaten as salad with oil and vinegar; or the raw fruit is filled with meat and rice and cooked, and are thus brought to the table. The small fruited Chillies are eaten in the green state, or allowed to ripen, and used as a condiment with meat. The Roumanian vegetable cultivators set out the plants at distances of 10 inches to 18 inches apart. By good applications of water the plants produce more fruits than leaves. The fruits (pods) are sold for about 10 centimes per 100.

"THE QUARTERLY JOURNAL OF FORESTRY" for April contains an interesting article on the planting of sand-dunes at Holkham, the Norfolk estate of the Earl of LEICESTER. The plantations are about 3 miles long and of an average width of about 300 yards. The primary object in view was neither forestry nor coast protection, but to secure an ornamental covering for the rather bleak, sandy hills. This appears to have been fully secured, and even hardwood trees are springing up. The trees originally planted and proving most successful are the Corsican, Scotch and Austrian Pines. The two former species seem to thrive best, and at the present time they are advancing towards the sea, and, though perhaps rather indirectly, are responsible for the reclaiming of formerly submerged ground, for the belt of trees causes an accumulation of sand and thus enables the dunes to extend in a seaward direction. But the dunes themselves then become occupied and fixed by the Pine seedlings, which spring up and take permanent possession of them.

"BIRD NOTES AND NEWS."—The quarterly publication of the Royal Society for the Protection of Birds (3, Hanover Square, W.) contains in its Spring Number an article on "Bird-Watchers," dealing with the urgent need that exists for the better protection of rare birds; reports of numerous Bird and Tree (Arbor day) celebrations promoted by the Society's Challenge Shield Competitions; notes on "The Plume Trade," "Economic Ornithology," portraits of the Society's President, the Duchess of SUTHERLAND, and of the Earl of STAMFORD, &c. The magazine is issued primarily to members of the Society, but can also be obtained for a subscription of one shilling a year.

EXPERIMENTS AT READING. The results of last season's experiments carried out by the University College, Reading, at the College Farm, Shinfield, have just been published in pamphlet form. An interesting experiment was that of testing the influence of weeds and hoeing on the crop yield. With this object in view, a quarter of an acre of Globe Mangels were sown on April 25, 1907. After the plants were set out, the plot was divided into five equal parts (each one-twentieth of an acre). (1) One lot was simply left to combat with the weeds, the total yield on this plot being 15¼ tons an acre. (2) The second plot was kept clean by hand-weeding only, no hoeing being done after setting out the plants. This yielded at the rate of 40 tons an acre. (3) A third, which was kept clean by repeated hoeings, yielded practically the same weight of roots (39½ tons an acre) as No. 2. (4) When only two hoeings were carried out, the yield was 37¾ tons an acre, and (5) when only once hoed, the weight of Mangels grown amounted to 33½ tons per acre. The difference between the weight of Mangels grown on the plot that was kept clean, and that where no weeding took place, amounted to 60 per cent. of the crop. The difference between hoeing once and hoeing twice amounts to four tons an acre. The results obtained, which are detailed in the report, are very suggestive, but it would be advantageous if the experiment were repeated during a dry season. For the purpose of making another experiment, one acre of ground on the farm was planted with a crop of Maize. Two kinds of seed were used, viz., Giant Caragua and White Horse Tooth. The seed, which was drilled the last day of May, was placed 3 inches deep in rows 24 inches apart. An application of 10 loads of dung and 3 cwt. of superphosphate was made to the acre; 1 cwt. of nitrate of soda was also applied as a top dressing. The yield of green fodder per acre amounted to 45 tons 18½ cwt. in the case of the former, and 49 tons 2¼ cwt. in the case of the latter. The report also contains much information as to the effects of applications of different nitrogenous manures on Mangels; the effects of manures on grass land, and the results of experiments on the laying down of permanent grass land. As these last-mentioned experiments have only been down for a short period, it is too early to draw any definite conclusions.

THE DEVELOPMENT OF FRUIT GROWING IN BRAZIL.—A writer in a recent number of the *Journal of the Society of Arts* gives an interesting account of this industry in Brazil. The vine is, naturally, one of the most important fruits grown in the country, and in order to encourage its cultivation, experts have been sent to Italy in order to acquire the necessary information as to the best methods in use. Furthermore, viticulturists from Sicily will, if possible, be induced to take up their abode at San Paulo. The Peaches, Figs, and Bananas figure among the most successful of the other fruits, and already a good market has been established for tinned and bottled produce. The cultivation of Oranges is also being undertaken, and many of the Coffee planters also have Orange orchards, but the abundance of wild Oranges, and the difficulty of transit at present render it difficult to obtain a satisfactory return for the necessary outlay. The Departments of Agriculture in Rio Janeiro and Minas Geraes have proved that many fruits belonging to temperate climates can also be grown with success. The great drawback to the advancement of the enterprise for the present lies in the difficulty of properly disposing of the fresh fruit, owing to the inadequate and expensive methods of transport. There seems to be a promising future for the establishment of canning factories, and also for the production of wine. The Agricultural Departments take an active interest in the development of these important industries, and Brazil in the future will probably be able to depend on herself for the supply of the canned and preserved fruits she requires, and also to export a considerable surplus to other countries.

SCHOOL GARDENS IN JAMAICA.—According to the *Agricultural News*, the section of the Jamaica *Report* for 1906-7 which relates to educational work in the colony contains the following note relating to school gardens and their educational value. "It is pointed out by the chief inspector of schools that certain changes made in the code last year have stimulated the formation and maintenance of school gardens with great educational benefit, not only to the school, but to practical agriculture in their neighbourhood. It should, however, never be forgotten that the main object of such work in elementary schools is in fact essentially identical with that of manual training. It aims at the training of the hand and eye and the general development of the powers of observation under circumstances, and in a medium, which correspond to the conditions under which a great majority of the children will earn their livelihood. A new officer who has had experience of their working in the United States has been appointed inspector of school gardens."

INSTRUCTION IN RURAL SUBJECTS IN ELEMENTARY SCHOOLS. It is pointed out in the *Journal of the Board of Agriculture* that a defect in most of the school gardening was that it is not dealt with as a branch of nature-study, i.e., as a study of the plant in relation to environment; the opportunity of developing the general intelligence of the scholars in rural work was largely lost. An attempt has been made in certain counties to provide a remedy by issuing a syllabus of nature-study for the

gardening classes But this is useless if the teachers are not themselves nature students, and it cannot be too strongly insisted that imposing a syllabus in such cases may lead to the worst form of text-book cramming Twenty-one counties already make some provision for affording the teachers a training in nature-study, but much remains to be done. A number of Saturday classes and summer courses in nature-study and gardening have been recognised. One of the most encouraging features in the school nature-study movement is the increase in the number of school exhibitions of nature-study and rural economy at agricultural shows and local flower shows. The exhibits have in many cases been of a very high order of merit. To the children, such exhibitions provide a stimulus; to the teachers they provide fresh ideas for work in their own schools; to the general agricultural public they demonstrate that the children's studies have a very real bearing on their future work in life. *Fruit culture.*—Of other rural subjects increased attention is being paid to fruit culture as a part of school gardening, thus carrying out the recommendation of the Departmental Committee on the Fruit Industry in Great Britain. The committee also advocated the teaching of gardening in training colleges. Bee-keeping is also sometimes associated with gardening or recognised as a subject of nature-study.

PRIZES FOR AGRICULTURAL STUDENTS.—The Board of Agriculture and Fisheries have received from Mr. MARTIN SUTTON and Sir GEORGE BARHAM, on behalf of the Dr. Fream Memorial Committee, of which the Earl of JERSEY was the president, the sum of £200, the income from which will be applied to provide a prize of books to be competed for each year by students in the science of agriculture. So long as an examination is held by the National Agricultural Examination Board for the National Diploma in Agriculture, the prize will be awarded to the person who obtains the highest marks in that examination. Owing to the generosity of an individual donor, the Board will be in a position to award a sum of £5 as a Fream Memorial Prize at the next examination for the Diploma.

Publications Received.—*The Trees of Commerce*, by W. Stevenson. Revised edition, extended to a notice of the higher or special branches of the Hardwood trade. (London: William Rider & Son, 164, Aldersgate Street, E.C.)—*Observations on the Cultivation of Roses in Pots*, including the Autobiography of a Pot-Rose, by William Paul, F.L.S. Ninth edition, revised. (London: Simpkin, Marshall, Hamilton, Kent & Co., 4, Stationers' Hall Court.)—*The Enemies of the Rose*, by George Massee, V.M.H., F.L.S., and Fred. V. Theobald, M.A. Illustrated by Miss C. M. Beard. Edited by the Hon. Secretary, under the direction of the Publications Committee of the National Rose Society.—*The National Rose Society's Annual for 1908.*—*The Cultivation of the Perpetual Flowering Carnation*, by C. H. Taudevin, (Cheltenham: Young & Co., Hatherley.)—*Proceedings of the Fifty-third Annual Meeting* (Western New York Horticultural Society), held at Rochester, N.Y., Wednesday and Thursday, January 22 and 23, 1908. (Rochester, N.Y.: Democrat and Chronicle Press.)—*Bulletin of Miscellaneous Information* (Royal Botanic Gardens, Kew), No. 3, 1908.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

THE SEASON AT EVESHAM.—In recent years gardeners in the Vale of Evesham have adopted much more extensively the cultivation of flowers than was the case a few years ago, and, generally speaking, they have found the industry remunerative. Wallflowers are now being sent to the markets, and are selling well, a preference being shown for the dark-coloured varieties. In the case of Narcissi, which are grown by the acre under Plum trees, it is essential to catch the right market, and in order to be able to sell at the best advantage it is requisite that the crop should be in full bearing at the White Festival of Easter. This was the case last year when Easter fell very early, and in accordance with the fitness of things this year, with Easter falling very late, the crop should have been all over too soon. The cold, wet spring, however, has so retarded vegetation of all kinds that the Narcissus is only just coming into bud, and the crop should be at its very best for the Easter festival. Those who have never seen Narcissi growing under the pure white blossom of the Plum trees can only form a very inadequate idea of the beauty of the scene. Gardeners in this vale have, so far, had a very poor spring, but there is compensation in the fact that with the fruit blossom held back, there is less liability of it being damaged by late frosts. In some places the blossom is very shy, and under the best conditions it is not expected that the crops can be anything like so heavy as those of last year. *H. S., Evesham, April 11.*

THE BLACK CURRANT MITE.—Mr. Johnson stated on p. 219: "I am of opinion that spraying with any insecticide that can be applied without injury to the bushes is useless." My experience is that it can be destroyed or cured by the lime and sulphur remedy. Four years ago the Black Currant bushes in these gardens were all so badly affected with the mite that I decided to destroy them. Before doing so, I purchased young trees from a reliable nursery, and planted them in another part of the garden, situated a good distance from the old plantation. When these young trees arrived they were apparently quite free from the mite, but the following year they proved to be badly affected. Soon after this I heard of the sulphur and lime remedy, which has in my case proved entirely successful, as at the present time not a "big bud" can be found. A gardener friend of mine who knew these trees were badly affected with the mite two years ago, called on me the other day, and when I told him the plants were now quite free from the mite, he expressed surprise, and searched among the trees for a big bud, but could not find one. My friend's trees are affected, and he has tried several remedies without success. *W. J. Snell, gr. to Viscount Clifden, Wimpole Hall, Royston.*

——— I was surprised to read in your last issue the letter from Mr. Wm. Johnson respecting Black Currant mite. It does not seem to be much use to publish information even in a valuable paper like the *Chronicle*. I have already twice written in your columns [see *G. C.*, May 21, 1904, p. 298, and May 13, 1905 ED.] saying that I have completely cured bushes which were badly affected with the mite by spraying during March, April, and May with the ordinary soft soap and quassia mixture. Of course, it is the soap which kills the mites. I don't suppose that the quassia chips have any effect whatever, but we use this remedy for other things and it saves the trouble of making a separate mixture. Then, again, Mr. Collinge has published in your columns from time to time (see *G. C.*, March 23, 1907, p. 193) the results of his experiments, which have proved very plainly indeed that sulphur and lime dusted upon the trees will also kill the mite. I have not tried Mr. Collinge's remedy myself, as the lime is apt to burn the foliage, which, of course, in a nursery is a grave objection, and I suppose the only reason why most people have not tried the soft soap mixture is that it is too simple. *A. H. Pearson, Lowdham Nurseries, Notts.*

CABBAGES.—Much of the history of the evolution of the Cabbage family appears to have been lost in obscurity. We have learned that certain forms of the tribe were known and cultivated 200 years B.C., although these seem to have been of very inferior character. In his lecture on March 31 last Professor Henslow told the Fellows of the Royal Horticultural Society that there seemed to have been from that time to the 16th century a long period during which members of this family, although existing occasionally under cultivation, nothing further was known about them. Professor Henslow's illustrations and remarks tended to show that for 18 centuries at least little was done to develop or improve these vegetables. But even from the 16th century until the present time, a period during which some very remarkable developments took place, nothing authoritative seems to be known as to the origin and gradual evolution of Cauliflowers, Broccolis, Brussels Sprouts, White and Red Savoy Cabbages, Borecoles or Kales, all of which must have developed from the wild species (Brassica oleracea), and not from B. Rapa, or other allied species to which the Turnip, Rape, and glaucous-leaved Kales are attributed. In reply to a question I submitted to Professor Henslow, asking him if any species of vegetable had evolved greater variation in form than B. oleracea, Professor Henslow replied that he knew of none that had done so. It has often been a matter for wonder whether any one original species could have produced such diverse varieties as the Cabbages, Cauliflowers, and Brussels Sprouts now in cultivation. Those who have inter-crossed these variations have found that all sorts of inferior and probably early forms are reproduced, but few varieties having any garden value. In the experiments of inter-crossing diverse forms conducted by Mr. Arthur Sutton, his recent lectures have shown the coarse and worthless nature of most of the seedlings. This would appear to show that the results we have at the present day in cultivation are the results of selection carried through a long period, probably amounting to centuries. *A. D.*

NUTTALLIA CERASIFORMIS.—Writing of this shrub in the *Gardeners' Chronicle*, March 28, p. 196, Mr. Fitzherbert remarks, "Not by any means tender, for it succeeds in gardens in the neighbourhood of London." I am forwarding a few flowering sprays taken from plants growing some 400 miles north of London. Here it is quite hardy, and in the early months of the year it is one of the most conspicuous occupants of the shrubbery by reason of its delicate light-green foliage. Very often when the buds are bursting the snow is still on the ground. The plant will thrive in almost any soil, but if given generous treatment it will throw out sucker-like growths in abundance; these afford a ready means of propagation if increase of the stock is desired. *Fred. W. Jeffrey, Woodend Gardens, Cathcart, N.B.* [Accompanying this note were freely-flowered shoots of this early-blooming shrub.—ED.]

WYDALE GARDENS, YORKSHIRE.—Wydale, Brompton S.O., the residence of H. Illingworth, Esq., is situated some eight miles from Scarborough. Mr. Scott, the gardener, has effected many improvements, and on the occasion of a recent visit to Wydale, I was impressed with a batch of seedling Clivias (Imantophyllums) in 6-inch pots, which Mr. Scott raised two years ago. They form the best batch of these plants I have seen. The colour of the flowers is exceedingly bright. Begonia Gloire de Lorraine and the Turnford Hall variety both showed evidences of good culture, and were a mass of bloom. Cyclamen and Primulas were also well grown, and the flowers of some of the Cyclamen were of very large size. The vines have been planted only two years, and they reflect credit on the cultivator. The varieties are Lady Downes, Black Alicante, Muscat of Alexandria, and Appley Towers. Mr. Scott speaks in high terms of the Appley Towers variety, which in his opinion is superior to many varieties commonly cultivated. *J. Snell, Kirby Misperton Hall Gardens.*

CYCLAMEN "MONT BLANC."

THE Cyclamen is not a difficult subject to cultivate, and a batch of seedling plants will always provide a good selection of colours for the greenhouse. Sometimes these plants will produce flowers of a particularly pleasing shade, and in some instances these special colours are perpetuated, until, by selection, the variety comes true to seed. By such means has been produced the beautiful salmon-coloured variety shown by Messrs. Hugh Low & Co. under the name of Low's Salmon, to which an Award of Merit was recently granted by the Royal Horticultural Society. Of equal value to the coloured varieties to the gardener in winter are the pure white kinds, such as is represented in Messrs. Ed. Webb & Sons' Mont Blanc variety (see fig. 111). The plant from which our illustration was prepared was photographed in Messrs. Webb's nursery at Wordsley, and, as will be seen on reference to the figure, is a very floriferous specimen and a good type of this useful plant.

SOCIETIES.

ROYAL HORTICULTURAL.

April 14.—The meeting held on this date was noticeable for many good exhibits of Narcissi, in addition to collections of spring-flowering subjects, Roses, forced shrubs, Carnations, and a large batch of Hippeastrums.

At the afternoon meeting of the Fellows, 60 new Fellows were added to the roll of the society, and a lecture on "Hardy Cacti and Other Succulents" was delivered by Mr. E. A. Bowles, M.A., F.L.S.

Floral Committee.

Present: W. Marshall, Esq. (in the chair), and Messrs. Chas. T. Druery, W. A. Bilney, R. C. Notcutt, John Green, T. W. Turner, C. R. Fielder, J. F. McLeod, Wm. Howe, John Jennings, W. Bain, Chas. Dixon, Geo. Gordge, Arthur Turner, Herbert J. Cutbush, Chas. E. Pearson, Wm. Cuthbertson, W. J. James, Chas. E. Shea, Edw. Mawley, R. C. Reginald Nevill, George Paul, and E. H. Jenkins.

Fig. 111.—cyclamen "mont blanc"; flowers white.

Messrs. Jas. Veitch & Sons, Ltd., King's Road, Chelsea, furnished a large table with flowering plants. At one end of the group was a fine specimen of Medinilla magnifica in flower, also many specimens of Xanthoceras sorbifolia. One of the most pleasing features of this exhibit was Erica propendens, with mauve-coloured flowers. There were also blue-flowered Hydrangeas, and a batch of plants of the beautiful Rhododendron Fosterianum, Boronias, Streptosolen Jamesonii, Crowea angustifolia, &c. As a separate exhibit, Messrs. Veitch showed a group of forced shrubs and trees. (Silver-Gilt Banksian Medal.)

Messrs. H. Cannell & Sons, Swanley, Kent, staged large trusses of scarlet Pelargoniums of the Zonal-leaved type, also plants of a pink-flowered Cineraria with revolute florets, named Gem of the Stars. (Silver Flora Medal.)

W. G. Vivien, Esq., Clyne Park, Blackpyl, South Wales, showed trusses of Rhododendrons.

A magnificent exhibit of dark-coloured varieties of Hippeastrums was shown by Alfred de Rothschild, Esq., Halton, Bucks (gr. Mr. R. Sanders). The plants were all unnamed seedlings. (Silver-Gilt Flora Medal.)

Messrs. H. B. May & Sons, The Nurseries, Edmonton, showed miscellaneous flowering plants, including Cinerarias, Roses, Pelargonium "Clorinda," Astilbe (Spiræa) japonica, and Salvia splendens "Pride of Zurich"; the last-named is valuable as an early-flowering, dwarf-growing variety, and the plant continues in flower throughout the summer months. The bracts are a rich scarlet. (Silver Flora Medal.)

Messrs. Hugh Low & Co., Bush Hill Park Nurseries, Enfield, made a fine exhibit of green-house flowering plants and winter-flowering Carnations. A draping of Lotus peliorhynchus along the front gave a fine effect to the group, which consisted of dwarf and standard plants of Roses, Ericas, Azaleas, Acacias, Meterosideros floribunda, &c. (Silver-Gilt Banksian Medal.)

Messrs. Carter, Page & Co., 52 & 53, London Wall, London, E.C., exhibited Violas in variety displayed in trusses in the usual pyramidal manner of exhibiting this flower; at the back being varieties of the large-flowering type of Pansy. Viola Admiration is a rich shade of blue; Kingcup, yellow; Dr. McFarlane, purple and violet; Molly Pope, yellow; Mrs. Rowland, rosy heliotrope; and Mary Burnie, pale sulphur yellow, are varieties of merit.

A small group of herbaceous Calceolarias was shown by H. D. Broughton, Esq., Birch Hurst, Andover.

A very showy group of forced shrubs was exhibited by Mr. Russell, Richmond Nurseries, Surrey, all the plants exhibiting good culture. (Silver Flora Medal.)

Very brightly-coloured but small-leaved Caladiums were shown by Mr. Chas. Turner, Royal Nurseries, Slough. (Bronze Flora Medal.)

A small, prettily-leafed Coleus named Coleus salicifolius nanus, was shown by Mr. W. H. Young, Mercury Nursery, Romford. The long, narrow leaves are red with deeper colouring on the margins.

Messrs. Jas. Carter & Co., High Holborn, London, staged a semi-circular group of Cinerarias, in the ordinary and the "Cactus" or stellata varieties.

Mr. Geo. Mount, Canterbury, again exhibited Roses, more numerous than at the last meeting, and even more beautiful. Blooms of such sterling varieties as Catherine Mermet, Richmond, Madame Abel Chatenay, Lady Ashtown, Mrs. John Laing, Captain Haywood, Prince de Bulgarie, and Ulrich Brunner were shown in large batches, the entire collection filling the whole of one of the long central tables. (Gold Medal.)

Messrs. W. Paul & Son, Waltham Cross, Herts., exhibited a group of Roses, the back plants being tall specimens of rambler varieties. Isabella, H.T., rose pink; Margaret, H.T., shell pink; Renee Wilmart-Urban, H.T., blush; Mrs. Aaron Ward, white, with a copper-coloured base; and Frau Ernst Borsig are all of this year's introduction, the first two being of Messrs. W. Paul's raising. (Silver Flora Medal.)

Messrs. Paul & Son, The Old Nurseries, Cheshunt, displayed flowering sprays and plants of uncommon trees and shrubs with boxes of Alpine plants at the front. A fine new Cytisus was noticed in the variety Daisy Hill, apparently of the Andreanus type; the keel is pleasingly blotched with brownish red, the remainder of the flowers being yellowish; Lonicera Maackii, Vitis Henryana, V. Coignetiæ, Acer colchicum aureum, &c. (Silver Banksian Medal.)

Some charming plants of greenhouse Rhododendrons, including R. × Fosterianum and R. Aucklandii, were shown by Sir Edmund Loder, Bart., Leonardslee, Horsham, Sussex (gr. Mr. W. A. Cook). (Silver Banksian Medal.)

Messrs. Wm. Bull & Sons, King's Road, Chelsea, London, staged a group of ornamental-leaved plants of stove and greenhouse varieties.

Ornamental Acers in variety were shown by Messrs. Thos. Cripps & Son, Tunbridge Wells, Kent. (Bronze Flora Medal.)

Messrs. G. and A. Clark, Ltd., The Nurseries, Dover, showed Polyanthuses and coloured Primroses, Aubrietias, Viola cornuta "Papilio," Anemones, Geum montanum, Primula rosea, and other Alpine and rock garden plants.

The Misses Hopkins, Mere Gardens, Shepperton-on-Thames, displayed Alpine plants in a well-arranged exhibit, representing a portion of a natural rock garden.

Messrs. Barr & Sons, 11, 12 & 13, King Street, Covent Garden, showed boxes of Alpine plants in variety.

Messrs. J. Cheal & Sons, Lowfield Nurseries, Crawley, Sussex, exhibited Alpine and rock-garden plants in five boxes, with dwarf shrubs and Conifers at the back.

Messrs. Geo. Jackman & Son, Woking Nursery, Surrey, displayed a small but pretty exhibit of Alpines, with sprays of flowering shrubs.

Messrs. W. Cutbush & Son, Highgate, London, N., showed an exhibit of hardy flowering plants arranged with skill in an imitation rockery. A prominent place was afforded well-flowered plants of Cypripedium pubescens, C. acaule, Trillium erectum, Ramondia Nathaliæ, Tulipa pulchella, Mertensia virginia, and Stylophorum diphyllum. On the opposite side of the table Messrs. Cutbush exhibited forced shrubs. (Silver-Gilt Flora Medal.)

Mr. C. F. Waters, Deanland Nursery, Balcombe, Sussex, exhibited vases of Carnations relieved with sprays of Asparagus Sprengeri. (Bronze Flora Medal.)

Mr. W. H. Page, Tangley Nurseries, Hampton, again exhibited vases of Carnations and bunches of well-grown flowers of Lilium longiflorum. (Silver-Gilt Banksian Medal.)

Carnations of fine quality were also shown by Mr. A. F. Dutton, Iver, Bucks, the effect being enhanced by long trails of Smilax. (Bronze Flora Medal.)

Messrs. R. Wallace & Co., Kilnfield Gardens, Colchester, exhibited rare and choice

species of rock-garden plants, with vases of Tulips. A curious plant is Carex Fraseri, the inflorescence being composed principally of the white stamens. (Bronze Flora Medal.)

Mr. A. R. UPTON, Millmead, Guildford, showed a batch of plants of Primula frondosa in a collection of other Alpine plants.

Messrs. JOHN PEED & SON, West Norwood, showed several boxes of Alpines, with Daffodils at the back.

Mr. G. REUTHE, Keston, Kent, showed Alpine plants, trusses of Rhododendrons, Lomatia pinnatifolia, Corylopsis pauciflora, Hepatica cærulea grandiflora, an old but rare garden plant; Saxifraga scardica, &c. (Bronze Flora Medal.)

A very representative collection of Alpine and hardy plants was shown by Messrs. WARE, LTD., Feltham. (Bronze Flora Medal.)

Mr. MAURICE PRICHARD, Christchurch, Hants, displayed seasonable Alpine and hardy garden flowers. (Silver Banksian Medal.)

Displays of Alpine plants were also staged by the Misses KIPPING, Hutton, Essex; Miss ALICE M. SMITH, Barnham, Bognor, Sussex, and Mr. H. C. PULHAM, Elsenham, Essex.

AWARDS OF MERIT.

Viburnum Carlesii.—This species was introduced from China, and a description of the plant is given with an illustration in our issue for October 11, 1902. The flowers are fragrant and of the purest white, reminding one of a glorified inflorescence of a white Bouvardia. Shown by Sir TREVOR LAWRENCE, Bart.

Cyrtomium falcatum var. Mayi.—A crested form of this well-known Fern, the ends of the fronds being sub-divided and much broader than in the type leaves. Shown by Messrs. H. MAY & SONS.

Narcissus Committee.

Present: H. B. May, Esq. (chairman), and Messrs. J. T. Bennett-Poe, R. Sydenham, F. W. Currey, John Pope, P. R. Barr, Geo. H. Engleheart, Chas. Dawson, P. D. Williams, G. W. Leah, Alex. M. Wilson, J. D. Pearson, E. M. Crossfield, A. R. Goodwin, H. A. Denison, W. W. Fowler, W. A. Milner, J. Jacob, F. H. Chapman, W. Poupart, R. W. Wallace, W. T. Ware, Chas. T. Digby, E. A. Bowles, G. Reuthe, W. Goldring, Jas. Walker, A. D. Hall, and Chas. H. Curtis (hon. sec.).

Messrs. BARR & SONS, Covent Garden, had a choice display of Narcissi representative of many sections, Fire Flame and Queen of Spain being noticeable among a large number. A fine collection of the Darwin Tulips was included in this group. (Silver Flora Medal.)

Messrs. POPE & SONS, Kings Norton, Birmingham, had many good varieties, amongst which Kings Norton, Lady Margaret Boscawen, and Boniface were noticeable.

Sir JOSSLYN GORE-BOOTH, Bart., Lissadel, Sligo, had many interesting varieties, including Gloire de Leiden, Albatross, Cresset, Lady Margaret Boscawen, Incognita, Mrs. R. Sydenham (a white Ajax), White Queen, &c. (Silver-Gilt Banksian Medal.)

Mr. CHAS. DAWSON, Gulval, Cornwall, had a delightful group of new varieties, in which the scarlet-crowned Charm, Mrs. R. Sydenham, Miss Mary, Red Bairn (a flower with a white perianth and scarlet-orange cup), Ptarmigan, Bracelet (with creamy perianth and scarlet-edged cup), Hypatia, a fine Engleheartii, Bedouin (with a rich scarlet cup), Bernardi (with a pale orange cup finely pleated), Buttercup (rich in colouring), Geoff (a fine bicolor Ajax), Cossack (a grandly-shaped Engleheartii, whose Leedsii white perianth has not a little of the finer poeticus shape), Pearl Diver (a white flowered seedling from Mrs. Langtry, with poeticus-like segments and pure white cup, a most charming flower), are a few of the best in this choice collection. (Gold Medal.)

Messrs. CARTWRIGHT & GOODWIN, Blakebrook, Kidderminster, showed a beautiful lot of Narcissi in choice kinds, such as Rising Sun (rich yellow self), Glee Maiden (Minnie Hume × Snowflake), a variety having a white Picotee edge, Argosy (a new giant Leedsii, Duke of Bedford (bicolor Ajax), Alice Knights, &c. (Silver-Gilt Banksian Medal.)

Messrs. CARTERS, LTD., High Holborn, had a batch of some 300 blooms of the large-flowered King Alfred. As an example of fine grouping this was a really superb lot.

Messrs. HOGG & ROBERTSON, St. Mary Street, Dublin, had a very fine assortment of Daffodils, including Lady of the Snows, King Alfred, Maggie May, Lady Margaret Boscawen, Atalanta, and Penguin. (Silver Flora Medal.)

Mr. R. O. BACKHOUSE, Sutton Court, Hereford, had a few varieties. The gem of this smallest group was White Admiral, probably the finest white Leedsii yet seen.

Mr. F. H. CHAPMAN, Rye, contributed many choice varieties of Daffodils as Horace, Cassandra, Will Scarlet, Weardale Perfection, King Alfred, &c.

Messrs. R. H. BATH, Wisbech, had a large assortment of Daffodils and Tulips in the best kinds; and Miss F. W. CURREY, The Warren Gardens, Lismore, Ireland, also contributed a choice assortment of kinds, as Chancer, Lady of the Snows, Geraldine, with red cup, Argent, Atalanta, Bennett-Poe, Lady Margaret Boscawen, &c. (Silver-Gilt Flora Medal.)

Mr. H. R. DARLINGTON, Park House, Potters Bar (gr. Mr. D. Bignall), was the only exhibitor in the "Barr" Cup competition, for which the prize was not awarded.

AWARD OF MERIT.

Narcissus Buttercup.—The parents of this rich-yellow, self-coloured Daffodil are N. odorus × N. Emperor. The colour partakes of the first-named parent and it also possesses not a little of its fragrance. It is a striking novelty, possessing richness of colour, fragrance, and good form. Exhibited by Mr. CHAS. DAWSON, Rosemorran, Gulval, Penzance.

Orchid Committee.

Present: J. Gurney Fowler, Esq. (in the chair), and Messrs. Jas. O'Brien (hon. sec.), Harry J. Veitch, H. Little, Stuart Low, W. Boxall, J. Forster Alcock, A. A. McBean, J. Cypher, F. M. Ogilvie, J. Charlesworth, W. Cobb, H. G. Alexander, W. P. Bound, H. A. Tracy, Gurney Wilson, R. Brooman-White, A. Dye, W. Bolton, F. J. Hanbury, De B. Crawshay, W. H. White, and F. Sander.

H. S. GOODSON, Esq., Fairlawn, Putney (gr. Mr. G. E. Day), staged an effective group, for which a Silver Flora Medal was awarded. Prominent in the group were the fine white Brasso-Cattleya Digbyano-Mossiæ Wageneri; a nice selection of Cattleya Schroderæ, and varieties of Odontoglossum crispum, including several spotted forms; O. loochristiense Tracyanum, a fine yellow, blotched with red-brown; Miltonia Phalænopsis, Cattleya intermedia nivea, and various Lælio-Cattleyas, &c.

Messrs. JAS. VEITCH & SONS, Royal Exotic Nurseries, King's Road, Chelsea, were awarded a Silver Banksian Medal for a group containing a good selection of Odontoglossum crispum, O. Pescatorei, O. triumphans, Cattleya Schroderæ, &c., together with two good forms of Zygopetalum crinitum, and a very rich orange-scarlet form of Ada aurantiaca with nine spikes.

Mr. A. W. JENSEN, Lindfield, Haywards Heath, secured a Silver Banksian Medal for a group of fine varieties of Cattleya Mendelii and Odontoglossum crispum, the latter represented by two types, the Pacho section having a grandly-blotched variety, a fine white flower, heavily marked with purple, and the other a small spotted variety of the punctatissimum class. All were of the best type.

Messrs. J. & A. A. MCBEAN, Cooksbridge, were voted a Silver Banksian Medal for a very pretty group of splendidly-grown Odontoglossums, Cattleya Mendelii, &c. Among the hybrids was a very charming hybrid between O. Rolfeæ roseum and O. crispum, Starlight. The flower was of fine shape and substance, and most exquisitely blotched and spotted with claret red, the lip being white. Among the O. crispum were several blotched forms, one imported plant flowering for the first time being very handsome. O. Hallii Charlesworthii, with two fine spikes, and Cypripedum Lawrenceanum Hackbridgense were also included.

Messrs. JAS. CYPHER & SONS, Cheltenham, staged a small group of very finely-flowered Miltonia vexillaria, Cattleya intermedia nivea, Masdevallia macrura, Lælio-Cattleya Dominiana, and a good selection of Odontoglossums, Brasso-Cattleya Thorntonii, &c. (Silver Banksian Medal.)

Messrs. HUGH LOW & CO., Enfield, staged a small group of Dendrobium Wardianum, with a plant of the pure white D. W. ochroleucum, D. barbatulum, Cattleya Schroderæ, good Cypripediums, &c. (Silver Banksian Medal.)

Monsieur MERIENS, Ghent, showed a selection of fine hybrid Odontoglossums.

Messrs. SANDER & SONS, St. Albans, and Bruges, showed Cypripedium Black Watch (Lord Derby × Curtisii, Sander's variety), a large and dark-coloured flower with shorter petals than C. Lord Derby. Dorsal sepal white, with a green centre, and closely-arranged dark purple lines; petals twisted, rose at base, white outward, spotted with claret red; lip brownish rose.

From the ROYAL HORTICULTURAL SOCIETY'S gardens, Wisley, came an inflorescence of the yellowish-green Cymbidium chloranthum.

[illegible] PEEL, Esq., sent Cypripedium ajax.

J. FORSTER ALCOCK, Esq., showed a very fine form of Lælio-Cattleya Highburyensis.

C. D. CRAWSHAY, Esq., Rosefield, Sevenoaks (gr. Mr. Stables), showed three plants of his Odontoglossum Urania (crispum × cristatellum), all varying in colour.

AWARDS.

FIRST-CLASS CERTIFICATE.

Cattleya Schroderæ "The Baron," from Major G. L. HOLFORD, C.I.E., C.V.O., Westonbirt (gr. Mr. Alexander). The phenomenal variety shown by Messrs. Sander & Sons at the Temple Show, 1905, and of which we reproduce the illustration prepared at the time. The sepals and petals are of a delicate white, the disc of the broad lip a blending of orange, rose, and purple.

Cypripedium bellatulum, Exhim's variety, from J. FORTSER ALCOCK, Esq., Northchurch, Berkhamsted. The finest dark variety of C. bellatulum known, the greater part of the flower being covered with intensely dark, blackish chocolate blotches.

AWARD OF MERIT.

Dendrobium Brymerianum, Gatton Park variety, from Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate (gr. Mr. W. P. Bound). A splendid form of this handsome, bright-yellow Dendrobium, the flower measuring 4 inches perpendicularly, and 2½ inches across the fringed labellum.

Cymbidium eburneum Goodsonianum, from H. S. GOODSON, Esq., Fairlawn, Putney (gr. Mr. G. E. Day). A singular variation with a white flower, having a broad rose-purple band down the middle of the lip.

CULTURAL COMMENDATION.

To Mr. W. H. White (Orchid grower to Sir TREVOR LAWRENCE, Bart., Burford), for a magnificent plant of the fine yellow Dendrobium fimbriatum oculatum with 40 spikes, the blotches at the bases of the labellums being very dark maroon.

To Mr. J. Davis (gr. to J. GURNEY FOWLER, Esq., Glebelands, South Woodford), for Masdevallia Schroderiana with 51 pretty white, crimson, and yellow flowers.

Fruit and Vegetable Committee.

Not much was presented to the notice of this committee, the chief exhibit being a variety of Rhubarb shown by Mr. T. E. DAWES, The Nurseries, Syderstone, Norfolk. The stalks were pale in colour and possessed little colour in the cup, but the plants were remarkable specimens on account of their size; one clump, with its leaves, weighed 63 pounds, and another had a total of 92 stalks. (Cultural Commendation.)

Sir EDMUND LODER, Bart., Leonardslee, Horsham, Sussex (gr. Mr. W. A. Cook), displayed a dozen dishes of Apples and three of Pears.

Mr. JOSEPH CHEAL, nurseryman, Crawley, showed fruits of Passiflora, Anona, Loquat, and other plants from the Madeira Islands.

Scientific Committee.

MARCH 31. *Present:* E. A. Bowles, Esq., M.A., F.E.S. (in the chair); Rev. W. Wilks, M.A.; Messrs. H. T. Gussow, G. S. Saunders, E. M. Holmes, A. Worsley, J. T. Bennett-Poe, H. J. Elwes, L. de B. Crawshay, G. Gordon, G. Massee, A. R. Rolfe, and F. J. Chittenden (secretary).

Inheritance of albinism in Orchids.—Mr. C. C. HURST, F.L.S., sent the following notes in relation to this subject, which has been brought up

at several meetings recently:—"Since my last communication, I have had an opportunity of examining some plants of Paphiopedilum insigne Sanderæ. Much to my surprise, I found distinct traces of purple sap in the basal margins of both the old and young leaves. The plants were not in flower, but I am told on good authority that some minute spots are also to be found on the dorsal sepal. In view of this, it would appear that P. insigne Sanderæ, so long regarded as an albino, is in reality a coloured form in which the purple sap is present in minute quantities. In accordance with the provisional scheme suggested in my last note, P. insigne Sanderæ will therefore be carrying both the colour factors C and P, and when mated with albinos may be expected to give coloured hybrids, as it has done in the case quoted by Mr. Rolfe. It would be interesting to know if the two other yellow forms P. insigne Sanderianum and P. insigne Macfarlanei, recorded as unspotted, are true albinos, and what they produce when crossed.

"If P. insigne Sanderæ is not an albino it must be deleted from my tables of albino crossings, which will now read as follows:—

TABLE A.

1. P. callosum Sanderæ (P) × P. callosum Sanderæ (P) gives albinos (P P).
2. P. Lawrenceanum Hyeanum (P) × P. Lawrenceanum Hyeanum (P) gives albinos (P P).
3. P. Lawrenceanum Hyeanum (P) × P. callosum Sanderæ (P) gives albinos (P P).
4. P. bellatulum album (C) × P. callosum Sanderæ (P) gives coloured hybrids (C P).
5. P. bellatulum album (C) × P. Lawrenceanum Hyeanum (P) gives coloured hybrids (C P).

TABLE B.

1. P. bellatulum album (C) × P. bellatulum album (C) should give albinos (C C).

"Mr. Rolfe's theory that the colour reversions are due to the fact that the albinos crossed belong to diverse species, fails to account for the cases in Sweet Peas, Stocks, and other plants where two albino individuals of the same species, variety, and race, may revert to coloured forms when crossed. On the other hand, the conception of complementary colour factors satisfactorily explains all the known phenomena of colour reversions in plants and animals, so far as they have been critically and experimentally studied."

Psocidæ injuring plants.—Some time since, Mr. STANTON BROWN, A.R.H.S., of The Cedars, Breadsall, Derby, sent a number of insects from Oleander, &c., which were identified as Caecilius Dali, an insect belonging to the Psocidæ, and known only to feed upon spores of fungi and similar things. Mr. BROWN now sent some pieces of recently-struck cuttings of Salvia splendens, upon which the insects occurred in great numbers. These cuttings were injured by insects, and Mr. BROWN said that the injury was solely due to the work of these insects, which did not appear at all particular with regard to the plants upon which they feed. This adds another to the already long list of insect pests in plant houses. Mr. SAUNDERS took the plants for further examination.

Larch with gall-like growths.—Mr. H. J. ELWES showed a one-year-old shoot of Larch taken from a young tree in his nursery having several gall-like growths along several inches of its growth. The shoot was referred to Mr. MASSEE, who undertook to obtain some information upon it if possible.

Orchid hybrids.—Mr. R. A. ROLFE, on behalf of M. E. CAPPE, Vésinet, France, exhibited two very diverse hybrids raised from the same seed pod of Lælio-Cattleya Cappei (a hybrid from L. cinnabarina × C. Warscewiczii), the result of fertilising a flower with mixed pollen from Lælia flava and Cattleya Mendelii. One flower appeared to be a true hybrid between L.-C. Cappei and C. Mendelii, whose characters were well blended, but the other closely resembled Lælia Cowanii (a supposed hybrid between L. flava and L. cinnabarina) in size. It was suggested as a case of dissociation of the "mixed character" whereby an ovule of L.-C. Cappei, from which the character of C. Warscewiczii had been eliminated, had been fertilised by a pollen tube from Lælia flava.

Scale insect on Holly.—Mr. SAUNDERS reported that the insect attacking Holly, shown at the last meeting from Ipswich, was the very local scale insect, Aspidiotus britannicus. He recommended that the Holly hedge should be thoroughly sprayed with paraffin emulsion, taking care that both surfaces of the leaves received the spray; or the hedge might be fumigated with hydrocyanic acid gas, if some means of enclosing it could be devised.

Yucca and Agave disease.—Mr. H. T. GUSSOW reported that he had examined the leaves of Yucca and Agave shown at the last meeting by Mr. SAUNDERS, and found they were attacked by the fungus Coniothyrium concentricum, a common fungus in America, and previously recorded in this country. He recommended that to stop its spread the leaves should be dipped in a 1 per cent. solution of copper sulphate.

HORTICULTURAL CLUB.

MARCH 31.—After the usual monthly dinner of this club, held at the Hotel Windsor on the above date, under the chairmanship of Mr. W. A. Bilney, the Rev. Joseph Jacob gave an interesting lecture on the Tulip and its history. The culture, as he pointed out, was one of considerable antiquity, since even as far back as 1554 their beauty was appreciated and recorded by noted botanists of the time, and both Clusius and Gerarde refer to them in 1573 and 1597. By 1634 indeed the Tulip had attracted so much attention and had produced so many varieties in evidence of its peculiar sportive character that the Tulip mania commenced, new forms fetching fabulous prices, one bulb of an unnamed form actually being sold for £5,000, and it is recorded that there being only two bulbs of a particular rarity, the owner of one paid a small fortune for the other, which he at once destroyed to render the remaining one "unique." Madness could hardly go further, and it is therefore not a matter of surprise that a reaction followed, so that in 1637 Tulip fanciers of the speculating kind tried to realise, with the result that a "slump" followed. The States-General of Holland stepped in and instituted regulations, and by 1638 common sense had reasserted itself. Eventually in 1730-40 popular taste turned to American plants, and Tulip cultivation fell into the background, but the varieties by this time ran into thousands. The first double Tulip, T. lutea centifolia, is recorded in 1665, and Parrot Tulips came to the fore in 1690. The origin of these appears to be somewhat mysterious, since they agree when in form with no known species. France appears to be the locality where they are first recorded. The curious fact was stated by the lecturer that in a catalogue issued at the end of the 18th century, the quoted varieties of Ranunculus far exceeded those of the Tulip, two bulbs of each of 500 kinds being offered for £30. In 1820 to 1840 there was waged the war between the Tulip connoisseurs of the north and south, the former considering the character of the marking to be the first essential and the latter the purity of the flower. The precise shape of the flower was also a vexed question, Glenny fixing it as a cup embracing one-third of a sphere; Groom, another authority, at one-half; and Slater, a third expert, at nine-sixteenths. In 1849 the National Tulip Society was founded, and Tulip cultivation was greatly in favour. In tracing the history of the flower up to the present date, the lecturer interpolated with the data above cited a number of very interesting facts relating to the introduction of new varieties and species.

CORNWALL DAFFODIL AND SPRING FLOWER.

APRIL 7.—The twelfth annual show of this society was held in the Market Hall at Truro, and, notwithstanding the lateness of the season, exceeded all earlier exhibitions in excellence. That the judges from the Council of the Royal Horticultural Society fully recognised the merits of the exhibits was shown by the number of medals that were awarded. They stated that never before had they seen anything approaching the collections of hard-wooded flowering shrubs that were staged, which, indeed, were superb. Rhododendrons were very fine and hardy spring flowers were largely shown, and included several rare and beautiful things. The management left nothing to be desired, the Hon. John Boscawen, who has been secretary since the inception of the society, fulfilling his arduous duties with conspicuous ability.

For the best collection of 30 varieties of Daffodils in commerce, the 1st prize was awarded to Mr. E. H. WILLIAMS for a fine stand of fresh flowers, of which Lucifer, Incognita, Firebrand, Homespun, Oriflamme, Beacon, White Queen, Armorel, Cassandra, Chaucer, and Herrick were especially noteworthy.

The best collection of 30 varieties of Daffodils, in commerce or not in commerce, was shown by Mr. J. C. WILLIAMS, who had a grand stand of unnamed seedlings, which deservedly received the only gold medal awarded. Of these, a variety known as "272," an enormous bright golden trumpet; "700," with white perianth and broad orange-scarlet cup; "415," pale primrose perianth and bright orange cup over 1 inch across, and "733," white perianth and wide yellow cup margined with glowing orange, were remarkably fine. The 2nd prize was won by Mr. P. D. WILLIAMS, with a stand only slightly inferior to the gold medal collection; this was awarded a Silver Flora Medal.

Nine classes were devoted to flowers obtained from bulbs costing not more than 10s., and in single blooms the 1st prize for Magni-coronati was won by Mrs. S. H. CHRISTY with Hamlet; the 1st prize for Medio-coronati was divided between Mrs. S. H. CHRISTY with Amazon and Miss M. WILLIAMS with White Lady. The 1st prize for Parvi-coronati was won by Mrs. W. TYACKE with Blood Orange, and the 1st prize for Poeticus by Mrs. W. TYACKE with Almira.

Groups of Daffodil seedlings that have not yet been in commerce for four years were very interesting. Mr. C. DAWSON won the 1st prize with Bernardino, Pilgrim, Dawn, Armorel, Rosella, and Fair Lady, a beautiful exhibit.

There were three classes for Polyanthi and Primroses, but the winning baskets were quite eclipsed by a large group of the Lanarth strain exhibited, not for competition, by Mr. P. D. WILLIAMS, which was awarded a Silver Flora Medal.

For 12 hardy spring flowers, Mr. P. D. WILLIAMS was awarded the 1st prize for Muscari, Heavenly Blue, Iris bucharica, Iris orchioides, Saxifraga cihata, Ranunculus asiaticus, Anemone Pulsatilla, A. apennina, A. blanda rubra, Caltha platypetala, Ornithogalum nutans, Chionodoxa gigantea, and Tulipa sylvestris.

For the finest plant of Rhododendron in the show, the 1st prize and Silver Banksian Medal were awarded to Mrs. J. P. ROGERS for a magnificent plant of R. suave measuring more than 6 feet in diameter.

The best group of Rhododendrons was shown by Mr. D. H. SHILSON, whose stand contained R. grande, Pink Pearl, Lady Alice Fitzwilliam, Countess of Haddington, and many seedlings (Silver-Gilt Banksian Medal). Mr. R. FOX had an exhibit almost as good, which was also awarded a Silver-Gilt Banksian Medal.

The classes for hard-wooded flowering shrubs produced, perhaps, the most interesting feature of the show, the entries being numerous and the exhibits of exceptional merit. In the class for 20 varieties there was little to choose between the first three exhibits. Mr. R. FOX was awarded the 1st prize, and included Forsythia viridissima, Staphylea colchica, Andromeda japonica, Daphne indica, Sutherlandia frutescens, Erica mediterranea, Berberis Darwinii, Acer rubet, Magnolia conspicua, Eriostemon lineanifolia, Grevillea thyrsoides, Cytisus racemosus, Spiræa Thunbergii, Drimys aromatica, Embothrium coccineum, Calceolaria violacea, Pittosporum eugenioides, Boronia megastigma, Magnolia stellata and Skimmia japonica (Silver-Gilt Banksian Medal). The 2nd prize and Silver Flora Medal were awarded to Mr. T. B. BOLITHO, whose stand contained the rare Viburnum rugosum, Boronia heterophylla, and Chorizema Lowii. The 3rd prize was won by Sir ARTHUR P. VIVIAN, who also received the Silver Flora Medal.

The best exhibit of six varieties of hard-wooded flowering shrubs was shown by the Countess of ILCHESTER, who was awarded the 1st prize and Silver Banksian Medal. The stand contained many superb blossoms of the lovely Magnolia Campbellii, which formed the most charming feature of the show. Mr. T. A. DORRIEN-SMITH sent a very interesting collection from the Isles of Scilly, which was awarded a Silver Flora Medal.

NON-COMPETITIVE EXHIBITS.

An Award of Merit was given to Messrs. CARTWRIGHT & GOODWIN for "Rising Sun," a golden trumpet seedling Daffodil of promise.

Messrs. ROBERT VEITCH & SON, Exeter, staged a fine exhibit, including Primula rosea, P. denticulata, P. cashmeriana, P. marginata, P. auricula, Corydalis cheilanthifolia, Lithospermum rosmarinifolium, Cytisus kewensis, C. scoparius, Clematis montana rubra, Azalea purpurea plena, Grevillea sulphurea, Eriostemons, Osteomeles anthyllidifolia, Correa cardinalis, Brachysema acuminata, and many other plants (Silver Flora Medal). The DEVON ROSARY, Torquay, showed a fine assortment of pot Roses in bloom, set off with Boronias, Acacias, Azaleas, Ericas, Cytisus racemosus, C. præcox, and Clivia miniata (Silver Banksian Medal). Mr. G. REUTHE contributed an interesting collection of rock plants (Silver Flora Medal). Messrs. BARR & SONS, who obtained a Silver Banksian Medal, made a fine display of Daffodils; they also exhibited a collection of rock plants. Messrs. W. CUTBUSH & SON provided a handsome show of plants, these including a large mass of Primulas in many species and varieties, Meconopsis Wallichii, Rhododendron racemosum, Fritillaria aurea, and other plants. (Silver Flora Medal).

SCOTTISH HORTICULTURAL.

APRIL 7.—A largely attended meeting of the above association was held on the above date, Mr. Whytock, the president, being in the chair. Mr. David King, nurseryman, Osborne Nursery, Edinburgh, read a paper on "Some Ideas regarding Planting for Effect."

In opening his paper, Mr. King referred to the cold, forbidding appearance which main entrances to policies and grounds from public highways often have. Avenues in general were, he said, "often one long weary stretch of gravel and grass." A pleasing effect is produced by the planting of groups of Abies, Picea, and Cupressus against a background of forest trees, the soft green of whose foliage contrasted well with the rich green of the Conifers. He also advocated the planting along avenues, behind a broad margin of grass, irregularly shaped groups of evergreen shrubs. Dealing with Rose gardens, Mr. King said he had seen many pergolas, in which too much of the structure but very little of the Rose was seen. Mr. King described some examples of trellising and pillars for Rose growing, constructed of rough Larch poles. A Rose-garden should dip gently to the centre, with high evergreen shrubs, such as Holly, Portugal Laurel, Yew, &c., all around for shelter.

Mr. King referred to a feeling of disappointment which he experienced when he first visited Chatsworth, and he contrasted the artificiality of the so-called waterfall at that place with a natural waterfall. In the latter part of the paper, Mr. King strongly advocated a more extended use of flowering trees and shrubs, both evergreen and deciduous, and by means of diagrams he gave a number of examples of artistic treatment of ground under varying conditions by means of these and other plants.

Some interesting plants were shown at the meeting, included amongst which were the new Spiræa "Peach Blossom," from Mr. D. W. Thomson, 113, George Street, Edinburgh; a flower stalk of Narcissus "Empress," bearing three flowers, from Mr. Balmer, Orphan Hospital, Edinburgh; and a single bulb of Hyacinth "Grand Maitre," bearing twelve flower spikes, from Mr. H. F. Cowan, 22, George Street, Edinburgh. A Cultural Certificate was awarded to Mr. John Fraser, Duddingston Cottage, Midlothian, for a plant of Tree Pæony "Lord Roberts."

SCHEDULES RECEIVED.

Bolton Horticultural and Chrysanthemum Society's 22nd exhibition, to be held in the Albert Hall, Bolton, on Friday and Saturday, November 20, 21, 1908. Sec., Mr. George Corbett, Heaton Grange Gardens, Bolton.

Sutton and District Rose Society's 27th exhibition to be held in the Public Hall, Sutton, Surrey, on Wednesday, July 1, 1908.

GARDENING APPOINTMENTS.

[Correspondents are requested to write the names of persons and places as legibly as possible. No charge is made for these announcements, but if a small contribution is sent, to be placed in our collecting box for the Gardeners' Orphan Fund, it will be thankfully received, and an acknowledgment made in these columns.]

Mr. C. F. MOWL, junr., for the past 2½ years Foreman in the gardens of the Right Hon. Viscount NEWPORT, Castle Bromwich Hall, Birmingham, as Gardener to A. J. ASH, Esq., Packwood House, Hockley Heath, near Birmingham.

Mr. THOMAS A. AYRES, for 10 years Foreman in the gardens of W. A. WYKEHAM-MUSGRAVE, Esq., Thame Park, Oxon, as Gardener to W. A. WYKEHAM MUSGRAVE, Esq., at the same address.

Mr. DAVID CALTHORPE, for over 2 years Gardener to Sir ALGERNON COOTE, Bart., H.M.L., at Ballyhn House, Mountrath, and previously in charge of Lord LANGFORD'S gardens, at Summerhill House, Enfield, co. Meath, as Gardener to A. D. CROSBIE, Esq., D.L., Bally Leigue Castle, Bally Leigue, co. Kerry.

Mr. JOHN JOHNSON, for upwards of 30 years Gardener to the late W. C. SPRAKER, Esq., Hazelshaw, Kenley, Surrey, as Gardener to A. S. TOMSON, Esq., Sunny Side, Kenley, Surrey. (Thanks for contribution to Royal Gardeners' Orphan Fund).

Mr. H. JOHNSON, for the past 4 years Foreman at Pennington Hall, Leigh, Lancashire, as Gardener to H. HARDY, Esq., Poole Hall, Nantwich, Cheshire. (Thanks for your contribution of 1s. 6d. to the R.G.O.F. box).

Mr. H. BEST, whose appointment was inserted last week, had previously served in the gardens at Bowood, Deepdene, and Sandbeck, but was not Foreman at Bowood.

Mr. G. ARSOLUM, for the past 6 years Foreman to the late Lady COX at Hillingdon House, Uxbridge, as Gardener to C. MURRAY, Esq., Eastcote Place, Pinner, Middlesex.

Mr. CHAS. M. HOLT, for 3 years and 8 months Gardener to THOMAS J. LENNARD, Esq., J.P., Henbury Court, Bristol, as Gardener to ARTHUR BAKER, Esq., Henbury Hill House, nr. Bristol, in succession to the late Mr. W. J. ORCHARD. (Thanks for 3s. which has been placed in the R.G.O.F. box.)

Mr. HENRY HAINES, for the past 7 years Gardener at Binfield Park, Bracknell, as Gardener to Mrs. M. A. JOHN, The Chantry, Ipswich. (Thanks for donation of 2s. for R.G.O.F.)

Mr. F. TARRY, for the last 6 years Second Gardener at Manor House Gardens, Alton, Hants, as Gardener to LLEWELLYN GRIFFITHS, Esq., Drayton Lodge, Longparish, Hants.

Mr. THOMAS WHITE, for the past 5½ years in the gardens at Broadwater, Weybridge (latterly as Foreman), as Gardener to C. C. NEWTON, Esq., Strafford Lodge, Oatlands Park, Weybridge. (Thanks for donation of 1s. 6d. sent for R.G.O.F.)

Mr. GEO. KIRK, for the past 12 months under Mr. WALKINGTON at Weelsby, and previously under Mr. T. COOK at Orford House, Market Rasen, as Gardener to W. BROWNE, Esq., Fintona, Bargate Avenue, Grimsby.

Answers to Correspondents.

A FLORIFEROUS HYACINTH: *F. C. T.* Your specimen bearing eight inflorescences with 105 flowers is remarkable but not unique. We have occasionally received examples with even more blooms. The side spikes have arisen from bulbs in the axils of the scale leaves, but which are still enclosed by the membranous leaves, giving the appearance of one bulb when there are really several.

ASPARAGUS: *W. W. C.* The Asparagus roots are infested with a soil fungus that has caused rotting. This is usually due to the tops being cut too early in the season.

BULBS: *J. R. P. & Sons.* The yellowing of the leaves is due to bacteria. The bulbs are also infected, and would transmit the disease next season to neighbouring bulbs. Burn all infected plants, and do not plant bulbs in the same soil for two or three years, unless it is sterilised with gaslime.

CULTURE OF PINEAPPLES: *J. H. S.* Read an article to be published in our next issue from Mr. Coomber, whose exhibits of Pineapples in recent years have been of the highest possible merit.

DAISIES AND PLANTAINS IN A LAWN: *A. B. E.* These weeds are not destroyed by the dressings of sulphate of ammonia, but the nitrogenous manure contained in the salt favours the growth of the grasses, and these in time crowd out the intruders. Apply the sulphate of ammonia now, or a week or two later, at the rate of ½ oz. to the square yard. This substance is the basis of the substance known as lawn sand.

INSECTS EATING PEACH AND NECTARINE LEAVES: *Correspondent.* The insects you send are weevils, voracious pests to all plants. The creatures feed at night time. They may be caught by laying white cloths under the plants upon which they are feeding, and after daylight has passed for about an hour, throwing a bright light on the plant, when the insects will be alarmed and fall to the ground. Should they not fall the plant should be shaken. Weevils hide themselves in the most cunning manner during the daytime.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. *Correspondents not answered in one issue are requested to be so good as to consult the following numbers.*

PLANTS: *Weekly Reader.* Both are very fine varieties of Dendrobium nobile, but for which we know no varietal names.—*Rachel.* Some of the numbers were detached. 1, Odontoglossum Pescatorei; 2, the narrow-petalled, brown-spotted flower O. pardinum; 3, O. Adrianæ; 4, O. Adrianæ of fine quality; 5, an indifferent, or immature flower of O. loochristiense.—*W. F.* 1, Dendrobium nobile (very good variety); 2, Dendrobium Pierardii; 3, Dendrobium dixanthum.—*F. R. I.* 1, Brassia caudata; 2, Odontoglossum Lindleyanum; 3, Oncidium obryzatum; 4, Aerides odoratum.—*R. S.* Catasetum atratum.—*A. B.* 1, Selaginella Willdenovii; 2, Pteris longifolia; 3, Adiantum caudatum; 4, Pteris tremula.

NARCISSUS: *H. P.* The yellow stripe is due to a bacterial disease, for which no satisfactory remedy is at present known. The removal and burning of infected plants is desirable.

PALM LEAF: *J. C. M.* The bleached spots are made by leaf-sucking mites. Sponge the leaves with an insecticide, allowing the solution to trickle down to the axils of the leaves, where the mites hide when not feeding.

PEACH BUDS DROPPING: *J. D.* See reply to *F. L. B.* in the issue for March 7 last, p. 160.

PEACH TREE: *A. S.* There is no fungus present to account for the injury to the branches. It is probable the roots are in an unsatisfactory condition.—*Thanks for Past Favours.* The primary cause is excess of moisture in the air. This has enabled the fungus Botrytis cinerea to establish itself. Plenty of ventilation will set matters right.

PELARGONIUM: *E. S.* Mites are the cause of the injury, and the two varieties mentioned are exceptionally susceptible. Isolate diseased plants, and sponge the leaves with a solution of soft soap.

THE BLACK LILY OF PALESTINE: *Vendys.* We suppose by this you mean Arum palæstinum sanctum, which is known as the Black Calla, or Black Arum Lily. The failure of the plant to flower is probably due to it being of insufficient size. Place it in a warm greenhouse and during the period of active growth afford the roots liberal supplies of moisture, with occasional manurial stimulants. During the late summer and autumn stand the plant in a warm spot in the open, and largely withhold moisture in order that the rootstock may be thoroughly ripened and become charged with an abundance of reserve material, so that its following season's growths may be sufficiently strong to produce flowers.

TULIPS: *C., Bros.* The Tulips are attacked by the fungus Botrytis parasitica. As the fungus is present in the bulbs received, all diseased plants should be burned, and the soil treated with quicklime.

ILLUSTRATIONS.

NEW PLANTS AT GHENT.

WE are enabled in this issue, and in the succeeding one, to publish illustrations (specially taken for us by Mr. A. E. Smith) of the new plants exhibited by Messrs. Sander & Sons, of St. Albans and Bruges, at the centenary exhibition of the Ghent Botanical and Horticultural Society now open at Ghent, in Belgium. These plants are included in the competitive group of 12 new plants, and as most of them have not yet produced flowers, the names given must be taken as provisional only. Compared with the new plants shown by Messrs. F. Sander & Sons at previous Ghent exhibitions, the present collection is not inferior, although it may not contain any such striking novelties as Acalypha Sanderi, Strobilanthes Dyerianus, Dracæna Godseffiana, and D. Sanderi, which have at one time and another figured at the Ghent exhibitions.

BROMELIA TRICOLOR: HORT. SANDER. Fig. 115.

In the absence of flowers, it is impossible to decide the genus to which this plant belongs. At first sight it might easily be mistaken for the variegated Pineapple, Ananas sativus variegatus, but it differs from that plant in habit, in the thinner texture of its leaves, and in the size and setting of their marginal spines. These, in the variegated Pineapple, are small, close set on a straight, even margin, whilst in Bromelia tricolor they are large, hooked, ¾ inch or more apart, and the margin is wavy. The leaves are 2 feet long by 1½ to 2 inches wide. The two plants can be distinguished by the softer Cordyline-like texture of the leaves of the Bromelia, just as Pandanus Veitchii differs from P. javanicus, with which it was at first confused. Bromelia tricolor was discovered some years ago on the Rio Negro, by Mr. L. Forget. He found only one plant, which arrived in bad condition, but it has since grown into a handsome specimen. The broad marginal bands of creamy yellow, and the rose-red colour on the young leaves and on the basal margins of the old leaves, the central portion of which is of a glossy green colour, are very decorative.

PHILODENDRON ILSEMANII: HORT. SANDER.

This plant is known only in its juvenile stage, and the leaves of Philodendrons often change very considerably as they get older. It is possible that P. Ilsemanii may be a form of P. rubescens or P. sagittifolium. It has the same habit, stem, and leafage as they have, but it differs from them and also from all other Philodendrons in having its oblong, cordate, dark green leaves splashed or marbled with white, and also now and then a tinge of rose-pink, particularly when the leaves are immature. The plant was discovered in Brazil by Mr. Forget, Messrs. F. Sander & Sons' collector. It should prove a good decorative climber for covering walls, pillars, &c., in tropical plant houses, and a useful bedding plant for gardens in tropical countries.

PERESKIA GODSEFFIANA: HORT. SANDER. Fig. 114.

This strikingly decorative plant is supposed to have originated in Queensland; at any rate, Messrs. Sander & Sons obtained it from that country. Botanically, it is probably a sport from the West Indian P. aculeata, known as the Barbados Gooseberry bush, which has been in cultivation for at least 200 years, and is largely grown in tropical countries as a fence plant. Here it is grown only as a stock on which Epiphyllums are grafted. It rarely flowers; indeed, although it has been cultivated at Kew ever since the foundation of that establishment, it has never been known to flower there except once, and that was in 1889. The flowers, which are pretty, are Cactus-like, 2 inches across, yellowish-white tinged with rose. The plant, although very variable in habit and foliage, is known only as a straggling bush or small tree, with more or less hooked spines in tufts. It grows very freely in tropical countries, as freely as Hawthorn does with us. For this reason P. Godseffiana, with its rich leaf coloration, is certain to become a popular garden plant in tropical countries. We can imagine a fence of it in such a place as Jamaica, where, when making fresh growth under the influence of bright sunshine, it would be wonderfully effective. Grown in pots under glass, P. Godseffiana requires plenty of sunshine and heat to bring it to perfection. It may prove to be a valuable shrub for summer effect out of doors in warm, sunny situations, and may even turn out to be a first-rate plant for summer bedding. The young leaves are rich crimson, apricot yellow and green above, the underside being of a uniform purplish-crimson colour; some shoots have leaves wholly yellow above and crimson below. The shoots grow rapidly, and the variation of colour on a specimen plant is quite extraordinary. Messrs. Sander are growing it in the form of pyramid specimens, as a climber for pillars, &c., and as a basket plant.

ENCEPHALARTOS WOODII: HORT. SANDER.

The discovery of a new Cycad in Zululand by Mr. Medley Wood, Curator of the Durban Botanic Gardens, Natal, is an event of some interest. Whether the plant now named in compliment to him will be accepted as a good species, distinct from the variable E. Altensteinii, we are not at present able to say, but it is quite certain that, for garden purposes, E. Woodii is as distinct from that species as the other recognised species of Encephalartos are. The largest plant seen has a stem 18 inches high and 8 inches through, with a handsome head of 25 leaves, which attain to 5 feet in length. They are gracefully curved, and are clothed with leaflets of variable size, the largest being 8 inches long and 2 inches wide. These are set about 4 inches apart on the lower part of the rachis, and more closely towards the apex, where they overlap. The broadest leaflets are irregularly pinnatifid, the strongest divisions and apex being spine tipped. The texture and bright shining green colour of these large pinnatifid leaflets easily distinguish this from all other species of Encephalartos. It grows well under cultivation, and is a strikingly handsome plant.

PTYCHORAPHIS SIEBERTIANA: HORT. SANDER. (Supplementary Illustration.)

The genus Ptychoraphis is exceptional among eastern Palms in its elegance, the three or four species known, all of them Malayan, being as graceful as Cocos Weddelliana and Geonoma gracilis. P. singaporensis and P. augusta, which are already in cultivation, although comparatively recent introductions, possess good decorative qualities, and in this new species, which is named in compliment to Herr Siebert, the highly-esteemed director of the Palm Garden at Frankfort, we have a most promising garden Palm. In the pose and form of the young plant there is a resemblance to Dæmonorops fissus, but there are no spines on the Ptychoraphis. The stems are slender, in the case of mature plants probably tufted, with elegant arching leaves, the petioles clothed with small brownish scales, the leaflets regular, 10 inches long, ¾ inch wide, tapering gradually to a long thread-like point. When young they are copper-coloured, changing with age to a rich green colour.

PINANGA MICHOLITZII: HORT. SANDER. Fig. 113.

A handsome dwarf Palm from Central Sumatra, where it was found by M. Micholitz. It comes near P. disticha (bicolor) of Blume, but that species is a native of Penang and Perak, and it has much shorter leaves. P. Micholitzii has dwarf, slender, tufted stems, with a bulbous base, and it forms an elegant specimen up to 6 feet high. The leaves are about a yard long, with slender, arching, sheathing petioles, dotted with blackish scurf; the midrib is rounded below, angular above; the leaflets are 15 inches long, variable in width, elegantly curved and attenuated, and of a rich green colour, conspicuously blotched with yellow above, glaucous green beneath; when young they are tinted with purple. The charm of this little Palm is in the elegance of its foliage and its pleasing variegation. It appears to be happier under cultivation than Pinangas generally are.

COCOS NUCIFERA VAR. AUREA.

The Cocoanut Palm is the most widely distributed and the most extensively cultivated of all Palms; consequently it exhibits considerable variation in stature, size, and form of fruits, the age at which it begins to fruit, and in leaf coloration. There is a variety known as nana, which has a very short stem, and bears fruit when it is about six years old. The golden Cocoanut introduced by Messrs. F. Sander & Sons is probably a form of this, characterised by the bright orange-yellow of the sheath, petiole, and midrib of the leaves, the colour of which is

heightened by the bright green colour of the leaflets. The ordinary Cocoanut is not looked upon as a garden Palm, but this golden variety deserves to rank with the red-stemmed or sealing wax Palm (Cyrtostachys Renda), which created such a sensation when shown at Ghent ten years ago by M. de Smet Duvivier.

ANTHURIUM LAUCHEANUM. HORT. SANDER. Fig. 112.

One of the most remarkable of the cultivated Anthuriums is A. splendidum, introduced in 1882 from Colombia by the late Mr. W. Bull, and described by Sir J. D. Hooker as a "truly splendid plant." It has ovate cordate leaves of a metallic green colour, and bullately reticulate, the habit of the plant being that of A. crystallinum. In this new introduction of Messrs. F. Sander & Sons, named by them in compliment to M. Lauche, we have a plant with the general characters of the well-known A. Andreanum, and leaves with the same striking reticulation as in A. splendidum. The stem is elongate, probably climbing by means of aerial roots; the leaves have smooth rounded petioles, and an oblong cordate blade from 12 to 15 inches long and 6 to 9 inches wide. Flowers not seen. Native of Colombia.

ANTHURIUM SANDERI. HORT. SANDER.

This has large, handsome leaves in the way of A. crystallinum, A. regale, and A. magnificum, but of nobler dimensions than either of them. Botanically, it comes nearest to A. magnificum, but it differs from that species in the form and nervation of its leaves. It has a short, stout stem, bearing symmetrically-disposed leaves, the petioles of which are up to 3 feet long, conspicuously angled and winged, the blade being cordate, 3 feet long and 2 feet wide, with the basal lobes wavy and less rounded than in A. magnificum, and a wide sinus, the lobes not overlapping. The upper surface is olive green, with silvery white, irregular bands along the midrib and nerves; the under surface is pale green, and the nerves are sharply angular or keeled. Flowers not seen. This will be a first-rate foliage plant for tropical houses, and if planted out on a mound or rockery in a peaty, well-drained soil, and kept moderately wet, it will probably grow to larger dimensions than those here given. Thus treated, all the big-leaved Anthuriums are most effective. For the introduction of A. Sanderi we are indebted to Mr. L. Forget, Messrs. Sander & Sons' energetic collector, who found it "somewhere in South America," which probably means Colombia.

NEPHRODIUM GRACILLIMUM. HORT. SANDER.

An extremely elegant variety of the Australian Nephrodium (Lastrea) decompositum, which is very variable in the size, texture, and cutting of its fronds, and in the habit of its usually wide-creeping rhizomes. Messrs. Sander & Sons obtained this plant from Brisbane, and it has proved so free a grower and the fronds are so finely divided that it is likely to become a favourite Fern with market growers. It has a close-growing rhizome, from which spring numerous fronds from 2 to 3 feet long, the stipes wiry, scaly at the base, the lowest pinnæ 12 inches long, those above being gradually shorter, the whole forming a deltoid elegant frond of pleasing appearance. The pinnules are as finely divided as in Onychium japonicum. The cultivated forms of N. decompositum are so different from N. gracillimum that it might reasonably be doubted that they are forms of the same species. There are, however, specimens of wild plants from Australia which prove their identity.

CALADIUM CENTENAIRE. (Supplementary Illustration.)

The modern garden Caladiums are more remarkable even than the modern tuberous Begonias. The film-like texture of the leaves, the variety in their size and form, and their often dazzling coloration are really wonderful characters to have sprung from the old Caladium bicolor, which was first introduced from Madeira about 150 years ago, where it was supposed to occur in the wild state. It is now known to have come from Brazil. The innumerable varieties of Caladium now grown—for they are bred not only in European gardens, but also in the tropics, many good ones coming from the gardens of South America—makes it difficult to say with certainty that any one is distinct from all the others. Nevertheless, one may say of C. Centenaire that it has exceptionally large and elegant leaves, whose shining black-purple petioles and rich, satiny, rose-red blades, with veins of a darker shade of red, place it among the handsomest of the big, unicoloured forms. It originated in Brazil.

CODLEUM (CROTON) FRED SANDER.

Garden Crotons are not Crotons but Codiæums, and they are all descendants from one species, viz., C. variegatum, which used to be called Croton pictum, and is the Aucuba of the tropics, being grown for fences, &c., in all tropical gardens where bright colours and a sturdy constitution are valued. It is said to have come originally from the Moluccas. So far as leaf characters go, no plant has developed such a multitude of forms and colorations as this; from broad to linear, from straight to spiral, trilobed, irregularly lobed and interrupted; and the marvel is why the leaves should have sported in this fashion. The shades of colour on the leaves also are as variable as they are often fantastic in arrangement. Crotons are ideal decorative plants, for they are easily grown, they pack and carry well, and they furnish colours that no other plants can. Consequently, they occupy a prominent place with market growers. The test of a good Croton lies in the way it strikes the market grower and decorator. It must be of good habit, bright, and pleasing in coloration, and able to stand the conditions of ordinary house decoration. These qualities are possessed by Croton Fred Sander, "the handsomest and most elegant of all trilobed Crotons, as it has the right habit, being elegant as well as leafy, and the leaves are bright green in the lower half and golden yellow in the upper half." This is the opinion of an experienced market grower.

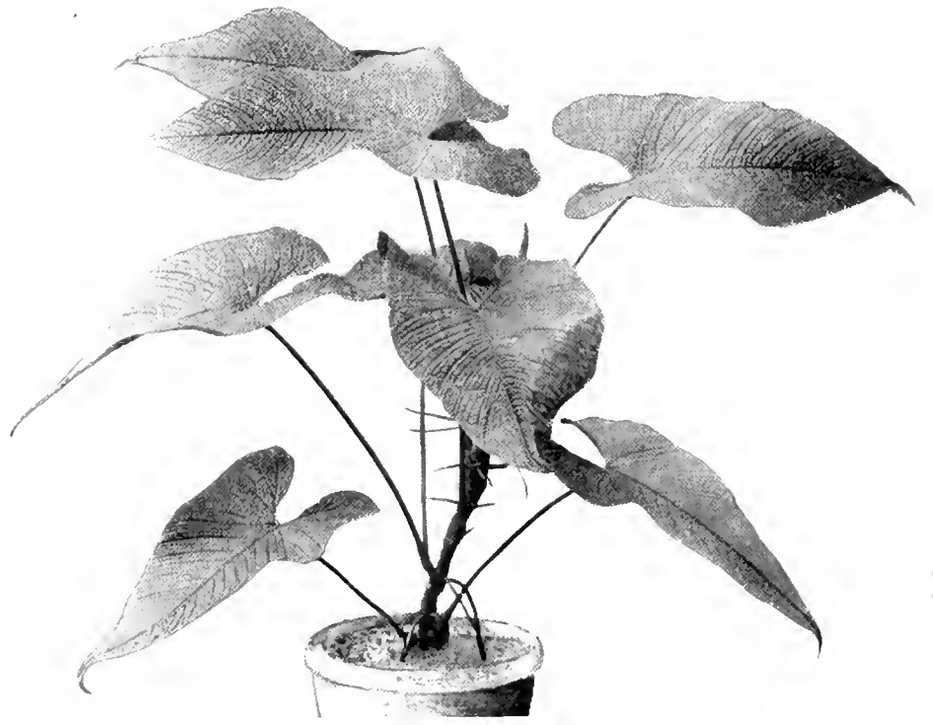

Fig. 112.—Anthurium Laucheanum: Hort. Sander., as shown at the Ghent International Exhibition.

CULTURE OF PINEAPPLES.

For the proper cultivation of Pineapples suitable structures are indispensable, although they need not be of an expensive character. Our houses are low with hip-shaped roofs. They are provided with adequate means of ventilation, and sufficient hot-water pipes to maintain the necessary amount of top and bottom heat. It is necessary, even in the coldest weather, to have an atmospheric temperature of from 70 to 80 degrees, and the heat of the bed in which the pots are plunged should be 90 degrees, and this should be possible without it being necessary to overheat the pipes. The pathways are sunk deep enough to allow the surface of the beds being made on a level with the surface of the surrounding ground; these beds are 3 feet in depth and composed of decayed tree leaves. This arrangement is economical, as less fire-heat is needed to maintain the temperatures in severe weather. The varieties of Pines most commonly grown are The Queen, of which there are several varieties, Smooth-leaved Cayenne, Charlotte Rothschild, and Black Jamaica; their cultivation is very similar, except in so far as it is modified in order to obtain ripe fruits at different seasons of the year. The Queen Pine, as cultivated for ripening fruits in summer, may be taken to illustrate the general cultivation of Pineapples. For a potting compost, light, fibrous loam is necessary, and this should be stacked in a heap long enough for its herbage to decay before it is required for use. The loam should be broken into suitable pieces for use in potting, and most of the fine particles shaken away from it. To each barrow-load of this fibrous loam a 7-inch pottul of dry soot should be added, also a similar quantity of bone meal or any good vine manure.

The plants are propagated by means of suckers, and those of The Queen intended for fruiting in summer should be potted early in September. When a sucker is detached from its parent plant a few of the lower leaves from

the sucker should be removed, cutting off the jagged ends closely. If the suckers are strong, they should be potted in well-drained pots having a diameter of 7 inches. The soil should be warmed before it is used, and by the aid of a potting stick during the process of potting, must be made very firm about the roots. Plunge the pots to the rim in a bed having a heat of 80 to 85 degrees, and do not let the atmospheric heat of the house fall lower than 65 or 70 degrees at night. It should be allowed to rise 5 or 10 degrees during the day. The house will need to be kept moderately close, and the plants should be shaded from bright sunshine, spraying them overhead with tepid water in the morning and afternoon of fine days, until the roots reach the sides of the pot. After this stage they will need to be watered with tepid water at the roots, rather more ventilation will be necessary, and little or no shade from sunshine need be employed. In winter the heat of the house should range from 55 to 60 degrees and the bottom heat 75 to 80 degrees. At that period the roots will not require much water, nor should the atmosphere contain much moisture. At the middle of February the plants should be fit for planting out in a bed or for potting into 12-inch pots. We find the latter more convenient. Before potting is commenced the balls of soil should be in a moist condition. First remove a few of the bottom leaves from the plant, then turn out the plant from the pot and remove the crocks. The potting should be done in a similar manner to that I have described for the suckers, and the pots afterwards may be plunged at 2 feet apart in a bed having a heat of 85 degrees. The atmospheric temperature of the house should be 60 to 65 degrees until the end of March, and until that time little water will be required by the roots. The summer treatment consists in carefully watering the plants so that the soil may be preserved in an equable condition of moisture, but by no means very wet. The roots may be fed regularly during the growing season by dissolving enough Peruvian guano in the water to colour it well. The temperature at night at that stage should be 70 degrees, and a little air should be admitted early in the morning, increasing the amount of ventilation when the heat reaches 80 degrees. Close the house early in the afternoon, after which time the heat may be allowed to rise to 90 degrees, the bottom heat being kept at 85 degrees. Spray the plants overhead early in the morning on fine days and again at closing time in the afternoon. Promote atmospheric moisture by damping the surfaces in the house as often as may be necessary. Remove any suckers as they appear, and afford the plants slight shade from powerful sunshine. As autumn approaches, the heat and moisture should be gradually decreased, until by the end of October, and during winter, similar conditions should be maintained, as I have recommended for newly propagated plants.

For the purpose of securing ripe fruits early in the summer, the night temperature may be raised to 65 degrees early in January, increasing it early in February to 70 degrees, allowing for rises by day in each case, and maintaining a bottom heat of 85 degrees. Carefully ventilate the house when the heat reaches 80 degrees, and gradually increase the ventilation as the heat of the sun increases. Maintain a moist atmosphere, afford water and nourishment to the roots as required, slightly shade from sunshine and remove the suckers, except those required for propagation, as I have recommended for the previous season's management. When the plants are in flower, a moderately dry atmosphere is necessary, and as soon as the flowers have passed, a stake should be placed to the fruit to keep it in an erect position. When the fruits are ripening, a moderately dry atmosphere with considerable ventilation is necessary, but no water should be applied to the roots. *T. Coomber, The Hendre Gardens, Monmouth.*

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM NOBILE "FRANCES RUNDLE."

This elegant variety has just bloomed in the collection of C. E. Rundle, Esq., at Deer Park Lodge, Tavistock, where Orchids are grown in immense variety, including many plants not often seen in these days of specialisation. The variety "Frances Rundle" is a well-formed flower of good substance, the sepals having a flush of colour on the reverse side. The petals are white; the lip is of the usual form with a good reniform blade, the shoulders of the side lobes being marked with a broad, short marginal line of purplish-brown colour. There are two "eye-spots," one on each side of the isthmus of the lip, and a linear, irregular broken series of markings down the median nerves; and, lastly, the distinguishing point of this variety, lies in the "picotee" edge of purple-brown all round the reniform blade of the lip in each of the six flowers the plant produced. This pretty margin makes the variety a very attractive one, and, if placed among thousands, it would immediately attract attention. I dedicate this plant to Mr Rundle's daughter as a testimony to a pleasant afternoon I spent with him among his plants. *de B. Crawshay.*

Fig. 113.—Pinanga micholitzii: Hort. Sander, as shown at the Ghent International Exhibition.

CULTURAL MEMORANDA.

LILY OF THE VALLEY.

When an old bed of Lily of the Valley is taken up because the soil has become exhausted by the plants, the grower has to select the crowns (young growths) for the formation of a fresh bed. A crown of Lily of the Valley flowers when it is three years old, and it does not flower again although it will continue alive, producing leaves, and thus help to starve its progeny. It, however, forms a rhizome or underground stem, which develops a bud annually, and these appear at a small distance from each other and push forth leaves.

Supposing a plantation be formed solely of three-year-old crowns, the crowns should produce blooms the following spring; but the buds that form on the rhizomes will not flower until they are three years old; so there will be a gap in the flowering lasting two years. In order to have blooms in successive years, a bed should be planted with a mixture of one, two, and three-year-old crowns, or a bed should be planted of three-year-old crowns annually, or three beds of one, two, and three-year-old crowns respectively, in which case the oldest bed should be taken up after flowering is over in the third year.

The ground chosen for the beds should be light and loamy, and be trenched two spits deep, a good dressing of manure, well decayed, being applied. Rank manure is injurious. When a Lily bed has been laid down for two years, a top-dressing of rotted stable manure, or that from a one-year-old hotbed, should be applied several times during the summer. If the plants seem to need extra assistance, weak manure water may be afforded. Too often the plants are neglected, and the flower-spikes are therefore short and weak. *F. M.*

THE FERNERY.

BRITISH FERNS.

Now that the beautiful varieties of our native Ferns are coming again into favour, and their culture, both by amateur and trade growers, is spreading extensively, a word of warning from one who has pursued the cult for more than forty years may not be inappropriate. About the middle of the last century Fern varieties were in greater vogue than at present, and their numbers were multiplied entirely disregarding the fact that the beauty of a Fern is altogether dependent upon symmetry of form and constancy of character. If we examine a catalogue of that time, we find the great majority were more curious than beautiful, and "irregulare," "crosum," "interruptum," "deficiens," "multiformis," &c., were characteristic names of the majority. It is a curious fact in Fern propagation by means of

spores, that while the symmetrical and perfect type of Fern, in which the character, crested or plumose, is evenly and distinctly evidenced throughout the plant, will, as a rule, produce equally good or even improved progeny, the Fern which shows any ruggedness, imperfection, or inconstancy is extremely liable to exaggerate these defects in its offspring. The fertility of such defective Ferns is frequently much greater than in the thoroughbred class, so much so indeed in some cases, that they spring up in profusion in Fern pots and pans, owing to the scattering of the spore crop.

Obviously such a facility of propagation is a snare to the trade grower as well as to the amateur, and there is not the slightest doubt but that the falling from favour of British Ferns fifty years ago was the direct outcome of putting these inferior types on the market. Some few years ago I visited what had once been a choice collection of British Ferns; the owner had died some time before, and the collection had been left to take care of itself. It was a dense jungle of "rogue" and inferior forms of the kind described, and all the choice ones had been starved and crowded out by their robust neighbours. Not long since I saw in a garden row after row of frames filled with similar inferior forms. Since the last "boom" a very large number of beautiful kinds have been produced, and there is now no excuse for another failure from similar causes. To maintain British Fern varieties in public esteem the selection must be made on very strict lines, and only the very finest types be catalogued for sale. Fortunately for the Fern lover, a young Fern very speedily asserts its true character. The third or fourth frond should decide the question of survival or destruction, since if there are defects up to that stage, it may be relied upon that they are inherent and persistent, and in that case it should be rooted out and destroyed. Another suggestion of vital importance to the trade exhibitor is that British Ferns should be treated as liberally as exotics. Specimen plants of exotic Ferns are cultivated and exhibited in such a manner that their full size and character are well in evidence, so that the purchaser may fully appreciate what can be done with them if only proper cultural conditions are afforded. British Ferns, so far, except on the occasion of the R.H.S. Conference in 1891, have never been so treated. Thumb pot examples are all very well for sale, but the full quality of the plant must be shown in a full-sized, well-grown specimen. *Chas. T. Druery, V.M.H., F.L.S.*

TOMATOS.

THE Tomato industry is still one that attracts new growers to try their skill in the production of this most popular fruit. There are important details in connection with Tomato culture—light, well-ventilated structures, good soil, and convenient water supply are necessary, in addition to a carefully-prepared feeding system, in which the food given may be utilised for building up each pound of fruit without any superfluous waste. Generally speaking, the troubles of Tomato growers are not serious when new houses, new soil, and other conditions are favourable. It is after the elapse of some years that extensive growers are perforce led to take careful note of how best to proceed in order to secure good crops, and freedom from fungoid diseases and animal pests, with little expenditure upon labour. Diseases and pests are difficult to avoid when continuous cropping with the same class of plants must necessarily be carried out.

Almost every grower at the present day has a carefully-selected type of Tomato, and were I to give a list of names it would, at least in many cases, lead to confusion. There are varieties possessing differences in foliage, fruits, internodes, and some have more perfect flowers than others, but each of these characters has scores of imitators. The points worth consideration concerning Tomatos are: the variety should produce plenty of pollen at almost every season of the year; it should have sturdy growths with short internodes, and therefore be capable of producing a maximum crop in as little space as possible. The fruits should be of good medium size, dense in flesh, and should take on colour early and mature quickly well up to the calyx. Many people who are carrying on a large trade in Tomatos trouble little about the names. They are, however, quick to note a heavy-cropping plant, or it may be that a fancy is taken to a type well cultivated in another nursery. When all is said and done, cultural methods have much to answer for as regards the crops taken from the plants, and everyone who grows Tomatos is soon taught that the plants are great feeders and cannot be grown successfully except under liberal treatment.

We have tested several methods for the production of early and very late fruits, and are in favour of pots for very early supplies, or else shallow beds on benches not far removed from the hot water pipes. It must be understood that, early in the season, too much soil is a great evil, and if it remains in a wet state for a long time it is a serious hindrance to healthy growth. Pots 8 or 9 inches in diameter are large enough for plants which will carry from four to six trusses of fruit. Usually the top trusses are the finest. When the growing point has been removed, the energy of the plant is concentrated in the development of the fruits. Remunerative crops may be had early from 6-inch pots topped at two trusses; and plants in 6-inch pots, raised from sowings made late in July, will give plenty of ripe fruits at Christmastime. Plants in these small pots may be placed rather closely together. For private use, many dishes of excellent Tomatos may be obtained late, and good fruits may always be kept for at least a month after the pots are turned out.

With the advent of March, plants raised from seeds sown in the autumn recover strength rapidly, and should be placed in their final pots early in the month. The compost should be on the dry side at the time of use, and firm potting should be practised. Advantage may be taken of maintaining high temperatures when bright, sunny days prevail, for such warmth does much good at this early season. We have frequently had excellent results from plants grown in conjunction with early Cucumbers, when the latter have been grown in low, three-quarter-span houses, using the back portion for the Tomatos. There are plenty of varieties that set freely enough under such conditions, and it is very rare for the fungus Cladosporium to attack Tomatos even under such treatment.

Of course, such plants are not suitable for yielding a supply over a long period. They are topped when they have produced three or four bunches of flowers, and when the fruits have ripened the plants are thrown away, and further plants cultivated under more normal conditions. We have grown Tomatos in an ordinary greenhouse, and these have furnished fruits for exhibition purposes not only in July, but in November also. The prolongation of the period of bearing is merely a matter of affording food in solution, and, of course, a soil mixture in the first instance that, with proper drainage, will keep in a sweet condition for a long time. There is nothing better for this purpose than old mortar rubble and charcoal, mixed in proportions varying as the staple soil is of a light or heavy character. The next important point is the maintaining of the surface soil in a healthy state, so that air and water may enter freely, and I know of nothing so useful as manure from a spent Mushroom bed, or manure specially prepared and sweetened before being used. If this is laid lightly on the soil, the surface is always open, and the manure becomes quickly permeated with roots.

In country gardens liquid manure for stimulating growth is usually easy to obtain, also

FIG. 114.—PERESKIA GODSEFFIANA: HORT. SANDER, AS SHOWN AT THE GHENT INTERNATIONAL EXHIBITION.

wood ashes, which are highly beneficial for mixing with the compost.

Some growers obtain compounded fertilisers, and others obtain the necessary items for mixing, or for applying separately. It is always wise to remember that Tomatos are capable of taking up their maximum amount of food when growth is most vigorous, and at such times superphosphate of lime is best utilised, when the formation of fruit is rapidly going on. A good liquid manure may be prepared by mixing 3 lbs. superphosphate of lime (35 per cent. sol. phosphate), 2 lbs. ammonia sulphate, and 1 lb. nitrate of potash, using ½ oz. of this mixture to one gallon of water, and regulating the application according to the growth and crop upon the plants. *C. Foster, University College, Reading.*

VEGETABLES.

TURNIP-ROOTED CELERY OR CELERIAC.

It has often been remarked in the horticultural Press that the kitchen gardeners on this side of the English Channel have never fully discovered the value of Celeriac, a variety of the cultivated Celery known as Apium graveolens rapaceum. And although the spur has been applied in this way time and again, matters have improved but little, for in nine good gardens out of ten the Turnip-rooted Celery is either absent altogether or it is cultivated so indifferently that the produce is second or third rate, and consequently little or no use is made of it. I am inclined to think that the fault lies not so much in the grower's ignorance of the existence of such a vegetable or salad, as in his want of knowledge in regard to the capabilities of the plant under cultivation in warm localities in this country. The large number of roots annually imported from the Continent and displayed during the winter months in Covent Garden and other important markets, have brought the vegetable under the notice of a large number of amateur gardeners, but these have not the knowledge that equally good roots might be grown in their own gardens, provided everything were done to make the cultivation as perfect as possible. The first thing to remember is that the plant will naturally succeed best in a warm climate and warm seasons. This fact should teach the gardener that it is necessary to sow the seeds in heat some time before the third week of March, in a rich, light compost contained in a box, just as one would sow Celery seeds. As soon as the seedlings are large enough to be handled, they should be pricked out into other boxes, in which they will have sufficient space to grow into plants of considerable size before they are planted out into their permanent quarters in May. After transplantation into these boxes, and when the plants have established themselves in the fresh soil, they should be gradually accustomed to a cooler atmosphere, keeping them in a position near to the glass where they will grow slowly but sturdily, thus acquiring such a habit that they will not be likely to suffer much check when the final transplantation is carried out. For the same purpose it is necessary that the compost in the boxes should consist of somewhat rough materials, especially putting some rough leafmould only partially decayed over the drainage material. If care is given to this detail, it will be found that, when lifting the plants from the boxes, some of the materials will adhere to the roots. Having thus obtained good plants before the weather permits of them being planted in the open air, the cultivator's next attention should be given to encouraging them to make the best use possible of the short summer season in developing large roots. In this case one need not be afraid of getting too much size into the produce, for the larger the roots the better they will be. Small produce is not appreciated, and often it meets with absolute rejection when offered to the cook. The site chosen for the plants should be one facing the south, and the best I can suggest is that of an outside vine border, which is usually some degrees warmer than any other spot in the garden. Let the soil be thoroughly tilled and richly manured, for, like Celery, the plant we are now considering is a gross feeder. Put out the plants in rows on the level soil, and allow each one a space of 1½ foot to 2 feet. During the growing season it is necessary to remove the suckers from the plants and a few of the lower leaves also. The surface of the ground should be stirred frequently, because the repeated waterings required by this crop are apt to cause the surface soil to cake, thus hindering the aeration of the soil. The waterings should consist of liquid manure from the farmyard and occasionally a pinch of some nitrogenous chemical manure may be scattered over the soil, watering it in with clear water. If these directions are properly carried out, the cultivator will be rewarded with fine, large roots, ready for lifting in November or later. Celeriac has a very agreeable flavour. It is prepared for consumption by boiling in salt and water until soft. Before boiling, thoroughly cleanse the skins, but do not remove them. After cooking the roots, allow them to become cold, then remove the skins, and either cut the roots into slices or shred them with a vegetable cutter. Serve with oil and vinegar or with a salad dressing. They may also be served hot with melted butter. Celeriac is at its best in the months of December and January, and is a favourite salad at Christmas time. *P.*

TREES AND SHRUBS.

PHYLLOSTACHYS FASTUOSA.

In some respects this is the noblest of all hardy Bamboos, and it is certainly one of the hardiest. It is said to be of Japanese origin, and was first introduced to Europe by M. Latour-Marliac in 1892. For several winters past it has suffered less than any of the taller Bamboos, several of which, although quite capable of withstanding our severest cold, are liable to have their foliage disfigured by the bitter winds that come so frequently with the New Year. This species, however, seems able to withstand the coldest weather untouched, and at the present time its leaves are quite fresh and green. A striking character of the plant is its stately habit. The stems are 15 feet or more high, quite erect, with the branches rather short and well furnished with leaves, thus giving a somewhat columnar aspect to each stem. The species is represented by two fine clumps near one of the entrances to the Bamboo Garden at Kew, each forming a dense, erect mass of luxuriant and rich green leafage. The underground rhizomes do not show any undue tendency to spread. This Bamboo has not flowered under cultivation, and has been provisionally put under Phyllostachys. It seems more probable, however, that it will eventually prove to belong to the Arundinarias. Although not yet very common in gardens, it deserves a place wherever Bamboos are grown and appreciated. *W. J. B.*

NOTICES OF BOOKS.

* "'The Studio' Year-Book of Decorative Art."

This volume covers a wide field, and contains designs of houses, furniture, &c., necessary for furnishing in the most modern and decorative of styles. The book is divided into sections, in which are illustrated modern productions of Great Britain, France, Germany, and Austria. Apart from the general interest of the book from the point of view of decorative art, it will doubtless be instructive to anyone who is about to build, furnish, or incidentally to lay out a garden. There are some charming specimens of houses, and some attractive suggestions for interior embellishment.

† "Gardening for Women."

Under the title of *Gardening for Women*, the Hon. Frances Wolseley has dealt with all matters appertaining to horticulture for women in a thorough and exhaustive manner. To those who intend to become lady gardeners, the book should prove of great use, for it contains practical advice, as well as much necessary information. We think the authoress has done wisely in encouraging only those who are fit to undertake the work, pointing out the pitfalls which lie before those who are unsuited for such a profession. Much harm has been done by women who are physically or otherwise unfit, and have commenced a task which has later to be abandoned, or, what is worse, have pursued it in a half-hearted manner.

‡ "Diet Difficulties, with Notes on Growing Vegetables."

Some useful and practical advice is offered respecting vegetarianism in the little book brought out under the conjoint authorship of Mrs. Earle and Mrs. Bryan. Various appetising recipes are among the attractions. The final chapter deals with the directions as to how to grow and cook some of the less known vegetables which are so often met with abroad. Their introduction and use in this country might easily provide a pleasant change from the ordinary vegetables we know so well.

§ The Case for the Goat.

This is a little work in which the case for the goat is stated by an enthusiastic believer in the value of goats for milking purposes. The author states in his "Introduction" that "Three acres and goats are feasible in many cases where Three Acres and a Cow are not within reach," and goes on to argue that on small holdings in cottage gardens, and even in connection with suburban homesteads it is possible to keep a goat or goats that will provide a supply of milk that possesses greater nutritive value than cow's milk, and milk that is less likely to contain the bacilli of tuberculosis. Having explained the peculiarities of the goat and her milk, and shown why goat's milk is to be recommended for the rearing of young and delicate children, as well as for general consumption, he proceeds to relate the actual value of goats and their milk in cash, and in discussing the objections sometimes raised to the keeping of goats, and to the consumption of their milk, he declares that their disagreeable smell is often exaggerated. Much can be done by good management to lessen this disadvantage. The information given on the necessity for obtaining goats of the best breeds, and for breeding from animals that are known to be good milkers, together with the instructions on the best methods of feeding and general management, will enable anyone desirous of giving the goat a trial to do this under conditions that are most likely to be attended with good results. The appendix contains answers from a number of experienced goat-keepers to 24 questions addressed to them by the author, and it forms a valuable feature of the book.

The Week's Work.

THE HARDY FRUIT GARDEN.

By E. Jordan, Gardener to The Dowager Lady Nunburnholme, Warter Priory, Yorkshire.

Peaches and Nectarines.—In the earlier districts the young shoots upon Peach and Nectarine trees will soon be sufficiently developed so that for the purpose of disbudding they can be rubbed off by means of the finger and thumb. The operation of disbudding should be carefully performed by an experienced man, and it should be carried out at intervals during two or three weeks, in order that it may not be necessary to remove so many at one time as would inflict a serious check to the trees. Commence first upon the most vigorous trees, beginning at the top of the tree and removing all the "foreright" shoots, i.e., those that are growing at right angles, or nearly so, with the wall. Afterwards remove a number of those growing from the sides of the branches, always leaving two well-placed shoots at the base of each branch. In some cases where there is a young fruit at the base, it is advisable to pinch the shoot back to about three leaves until the weather is a little warmer, because many of these fruits will have to be removed later, and the remainder of the shortened shoots can be cut out at the same time. In the course of a few days or a week the trees should be again examined for the purpose of removing any weak shoots or others that will not be required for furnishing the tree. When the process of disbudding has been completed there should be one healthy shoot at the base of each branch and another at the end of the branch which will be needed as a leader. In some cases where the branches are of extra length one or even two shoots may be retained in the middle of such branches if there are open spaces upon the wall needing to be furnished, but do not be tempted to retain more shoots than there will be ample room for next season. Some cultivators retain the best shoots whether they originate on the upper side or underneath the branches, but for the lower part of the tree it is certainly better to select those on the upper side, as they generally grow with greater vigour, and this is the most difficult part of the tree to keep in good order. In the case of young trees a sufficient number of shoots must be left to keep the base of the trees well furnished, but even on these, the shoots should not be more thickly placed than at distances of 4 or 6 inches from each other. Do not stop any leading shoots unless they are excessively strong, in which case the points may be pinched out. Examine the trees frequently and if it is found that any aphides are present, dust the infested shoots with tobacco-powder. When the fruits have set, this powder may easily be washed off the trees by water applied by means of the garden engine. Continue to draw down the blinds at night time as a protection against frost. Examine any trees that are growing on light soils and afford ample water to the roots if it is necessary.

Thinning the fruits.—Read the remarks on this operation in connection with Apricots in the last issue. It should be carried out concurrently with that of disbudding, leaving at the first operation a large number of well-placed fruits, many of which will be removed at subsequent thinnings, especially after the stoning stage is past. It should be constantly borne in mind that it is desirable to secure a good crop of fruits evenly distributed over the whole tree.

THE ORCHID HOUSES.

By H. G. Alexander, Orchid Grower to Major G. L. Holford, C.V.O., C.I.E., Westonbirt, Gloucestershire.

Phalænopsis. The present time is suitable for effecting a thorough overhauling of these plants, before they have made many fresh roots. The temperature is now sufficiently high to encourage the plants to make fresh growth immediately afterwards. In the case of Phalænopsis, it is undesirable to disturb the roots more frequently than is absolutely necessary; but however carefully a compost is prepared, it is sure eventually to become loose in texture and sour in condition. When this stage is reached plants will suffer a check unless they are removed to fresh receptacles and afforded new compost. Phalænopsis may be cultivated with equal success in pots or in teakwood baskets, but we prefer to use baskets, as the roots of the plants appear to like the wood, and they certainly live for a longer period than if contained in pots. In either case, the cultivator must provide ample means of drainage, using for this purpose clean broken crocks and lumps of charcoal, working these carefully in amongst the roots. The compost for the rooting material may consist of clean, chopped sphagnum-moss two-fifths, polypodium fibre two-fifths, and osmunda fibre one-fifth, with an addition of a good sprinkling of crushed crocks and charcoal. Do not disturb any specimens which appear healthy and have their roots clinging firmly to sound receptacles, except in so far as is necessary to remove any of the decayed compost or loose crocks from the surface, also to make the drainage good and apply a top-dressing with fresh material. Press the potting compost carefully and firmly amongst the roots, and apply on the surface a layer of freshly-picked sphagnum-moss. Great care is needed in transferring plants from old to new receptacles. Having carefully picked out the old compost and the drainage material, plunge the receptacles containing the plants into a pail of lukewarm water for the purpose of loosening the roots attached to them. They may then be detached by means of a thin-bladed knife. After this operation has been carried out, select for each plant a new pot or basket of a suitable size, and treat it as I have already advised. The plants having been thus disturbed, will need for a time a kind of convalescent treatment, giving them rather more heat and shade from sunshine than they have had hitherto, keeping the atmosphere very moist, and spraying the plants overhead on bright days. It is usual to have these plants in the East Indian house, but if a structure is specially set apart for them, the heat may now be from 70 to 75 degrees during the day, allowing a rise of 10 degrees by sunheat, but it should fall to 65 or 70 degrees by night. I do not recommend that these plants should be grown in a close, stuffy atmosphere and densely shaded, it being better to use more moderate shading and to afford ventilation in suitable weather. The ventilation may be increased as the plants become better established, at the same time, decreasing the shade as much as it is safe to do. In summer, when the plants are in most active growth, they need an ample supply of water at the roots, and a quickly circulating atmosphere. If any flower-spikes show themselves on newly-potted plants before they have become established, thin out the number of flowers upon the spikes, but do not remove the inflorescence altogether, as this would probably cause secondary ones to be produced.

Pleiones.—Increase the supply of water at the root to all these plants that are now growing and rooting freely. Afford them a position on a shelf, or suspend them near the roof glass in a cool intermediate house where they will be exposed to the sunlight. Syringe the under sides of the foliage twice daily to keep red spider in check. Where no dried cow manure was used in the potting materials, weak doses of liquid cow manure might be given to healthy, well-rooted specimens during the growing season.

PLANTS UNDER GLASS.

By Thomas Lunt, Gardener to A. Stirling, Esq., Keir, Perthshire N.B.

Luculia gratissima. This plant succeeds best when the roots are planted out in a border, and the border should be composed of light, fibrous loam, leafmould, and sand in equal parts. The warm greenhouse is the proper structure for its cultivation, and it succeeds well if trained up a wall or rafters, where the plant is exposed to plenty of light and will not receive shade from sunshine. Being a plant liable to attacks of red spider and thrips, it should be syringed on all favourable occasions, and care should be taken to see that the water is thrown well on to the underside of the foliage. During active growth the roots may be fed liberally with liquid manure in a tepid condition. Luculia gratissima seldom succeeds well if the roots are confined in a pot, but if this has to be done I would recommend the use of pots as small in size as convenient, employing a compost of peat, loam, and sand in equal parts. The interior of the pots must be clean and well drained. In repotting a plant let it be given just a small shift, and in training the shoots let them be kept always in an upright position.

Euphorbia (Poinsettia) pulcherrima.—Remove the old plants of this species from their resting quarters, and place them in an atmospheric heat of from 55 to 60 degrees, in a position near to the glass and fully exposed to sunshine. Apply a good watering to the roots, which will encourage the plants to start into growth. Directly the shoots are 3 or 4 inches in length, they may be taken off with a "heel" attached to each and inserted singly into small thumb pots containing a mixture of leafsoil two parts, loam one part, and sand one part, first passing all these materials through a ¼-inch sieve. Let the cutting be inserted in the centre of the pot, and, after the insertion of the cutting, fill up the hole made by the dibber with silver sand. Then press the soil firmly. Plunge these pots in a hotbed, and let the atmospheric temperature at night be 70 to 75 degrees, which will cause the cuttings to make roots quickly. As soon as this stage is reached the little plants should be removed to a position close to the glass, and after the elapse of a further week or so, they may be given a heat of 60 degrees, gradually hardening them that they will be able to stand full exposure to sunshine. When it is found that the roots have extended freely round the sides of the pots, they should be repotted into pots 3 or 4 inches in diameter. The potting compost may consist of loam two parts, leafmould one part, and sand one part, adding a moderate sprinkling of bonemeal and a small quantity of manure from a spent mushroom bed. When it is necessary to repot the plants again into 6 and 7-inch pots, a similar compost may be used, and during the summer months the plants may be cultivated in an unheated frame containing a floor formed of coal ashes. Free ventilation must be employed at all times, and a small quantity of air must be admitted very early in the mornings.

Euphorbia jacquiniæflora.—This species may be treated as the one already discussed, excepting that it needs rather more heat throughout the season.

FRUITS UNDER GLASS.

By T. Coomber, Gardener to Lord Llangattock, The Hendre, Monmouthshire.

The late Peach house.—In these gardens this house is 100 feet in length, and it contains 12 fan-trained trees, thus it furnishes a supply of Peaches over a considerable period, which lasts until Peaches are obtainable out-of-doors. At the present time peach trees of this description require careful attention in the matter of disbudding shoots. This work should be carried out at intervals of a few days, and when finally completed a sufficient number of young shoots should have been left to adequately furnish the tree in all its parts. These shoots should be carefully trained into position as they extend in length, and the thinning-out of the fruits should be practised at intervals during the same period. Syringe the trees thoroughly both in the morning and afternoon, and apply water to the borders as often as necessary, also liquid manures, or artificial manure as may be preferred. Ventilate the house early in the morning if the heat has risen to 50 degrees, gradually increasing the ventilation on bright, warm days until the ventilators are fully open. The ventilation should be just as gradually reduced during the afternoon, eventually closing the house when the heat is at 55 degrees.

Early Melons.—The flavour of Melons is greatly influenced by culture, especially during the time the fruits are approaching maturity. At that stage the atmospheric temperature at nights should be 70 degrees, and the front and back ventilators should be left very slightly open during the night. The atmospheric condition of the house by day will vary with the character of the weather, but the presence of much moisture is detrimental to the flavour of the fruits. At such times the use of liquid manures should be discontinued, and the supply of water at the roots should be curtailed, but not to a degree that would cause the plants to flag, for if watering were afterwards resumed it might cause the fruits to split. Gather each fruit as soon as it shows an inclination to crack round the foot stalk, and place it in the shade in a well-ventilated, warm place to fully ripen. When all the fruits have been gathered, clear out the plants and cleanse the house in preparation for late crops, which will need to be cultivated on a system very similar to that recommended for the early Melons.

Successional Melons.—These plants will need attention in various ways according to their stage of growth at the time. Attend as may be required to pollinating the flowers, and seek to obtain a set of three fruits to each cordon plant, after which further blossoms may be removed. Stop the shoots at one leaf beyond the fruit, and secure them to the trellis, thinning out any others as may be desirable to prevent crowding. Top-dress the roots and keep them well nourished with suitable stimulants, including liquid manure, bearing in mind that Melons, being a quickly-growing crop, are apt to suffer considerable injury if neglected even for a short period. Afford supports to the fruits when they become necessary. If no nets are available, strong pieces of raffia crossed under the fruit and tied to the trellis answer very well. Do not shade the plants more than is necessary, but if the sun should shine powerfully after a period of several dull days, the plants may suffer unless slight protection is afforded them. Sow seeds each fortnight in order to raise plants that will maintain a regular supply of ripe fruits.

Tomatos.—Plants which were raised to produce the main crop are now in a fit condition for planting out, or if it is intended to keep them in pots, they are ready for the final potting. In our case, they are placed in a pit that has lately been occupied by Strawberries. They are planted upon a moderately small, firm ridge, composed of three-fourths loam and one-fourth horse manure, with additions of wood ashes and fine mortar rubble. The ridge is placed immediately beneath the bottom wire of the trellis. In planting, it is necessary to turn the plants out of their pots very carefully, and by the aid of a rammer make the soil very firm about the roots. Plant them at distances of 18 inches apart. Tie the tops of the plants to the trellis and train them as cordons. If the plants are to be fruited in pots, place them into pots 12 inches in diameter, and provide good drainage. Make the soil firm in the pots, and place the plant sufficiently low that it will be possible to afford top-dressings as these may be required. If it is possible to plunge the pots in a slightly warm bed composed of stable manure and partially decayed tree leaves, so much the better. Remove lateral growths from each plant as they appear. Pollinate the flowers at mid-day as often as necessary.

THE FLOWER GARDEN.

By W. Fyfe, Gardener to Lady Wantage, Lockinge Park, Berkshire.

Sweet Violets.—The plants in unheated frames are now growing freely, and a supply of runners may now be obtained to increase the stock. Each runner should be secured with a few roots attached to it. If a partially-shaded border was well prepared in the autumn by the free addition of partly-decayed leafsoil and good rotten manure well dug into the soil, it will now be in good condition for planting. Dibble in the runners in rows formed at 2 feet apart, allowing distances of 1 foot between each plant. Insert them just deep enough in the soil to make them secure, pressing the soil firmly around each runner as planting proceeds. When the planting has been finished, apply a good watering, and sprinkle the plants daily with water until they are well established. Remove any runners that may form, and make frequent use of the hoe to keep the surface of the ground in a loose condition. If red spider is troublesome, cover the ground with fresh horse droppings from the stables, and keep them frequently moved with the hoe. In dry weather apply frequent waterings with the hose. If Violets are planted in different aspects the flowering season is prolonged; but the best position for them is one that is shaded from the mid-day sun. Princess of Wales and La France are good single varieties; Marie Louise, Lady Hume Campbell, and Swanley White are double varieties worthy of cultivation.

Montbretias that have been wintered in cold frames have made sturdy growth, and, being well hardened, they may now be planted out in ground previously prepared by trenching and manuring. When planting in groups for effect they may be placed from 4 to 6 inches apart, but if intended for special culture they should be planted in rows formed at 1 foot apart, and at distances of 6 inches in the rows; this will permit of the hoe being used conveniently.

Campanula pyramidalis.—For outdoor and indoor decoration this Campanula and its white variety are very valuable, but the plants must be at least 12 months old from seed. Having been wintered in unheated frames, they may now be transplanted to their permanent positions. Do not disturb the roots more than is necessary, but, in planting, make the soil firm about the roots of each plant, and finish off at a little above the ground level.

Cortaderia (Gynerium) argenteum.—The present is a good time for planting the Pampas Grass, or for overhauling clumps that have become bare in the centre. Dig out the exhausted soil to the depth of 2½ feet, and replace with good loam and manure, using about three parts of the former to one part of the latter. Replant only the healthy portions of the clumps, and allow sufficient distance between each to provide for the rapid growth of which these plants are capable. The Pampas Grass is very effective if planted near to water, or upon the rockery, or as a single specimen on the lawn. The plants need an abundance of water in summer. The female plant is much the better in form and colour.

THE KITCHEN GARDEN.

By E. Beckett, Gardener to the Hon. Vicary Gibbs, Aldenham House, Elstree, Hertfordshire.

Onions.—Autumn-sown plants which have been duly transplanted have become established, and every encouragement should be given them to make uninterrupted growth. Abundance of liquid manure should be applied to the roots, either drainings from the farmyard or sewage are very suitable. During showery weather some patent vegetable manure and soot may be applied alternately. The surface soil should be kept constantly stirred by means of the hoe, and during hot, drying days the plants should be sprayed with clean water during the afternoon. The planting out of any Onions which have been raised under glass during the spring should be completed as speedily as possible on ground which has been previously well prepared. Care should be taken to lay out the roots carefully and plant very firmly. Apply a good dressing of soot, and unless the weather is showery, damp over the tops two or three times daily. Permanent crops which were sown in the open should have the surface soil loosened with the Dutch hoe immediately the young plants can be well seen, and, at the same time, a good dressing of fresh soot and finely-sifted wood ashes should be applied.

Last year's stock.—The stock of old bulbs should now be examined and any which have commenced to grow may be placed in the ground for furnishing young growths for salading purposes. These are generally appreciated, being much milder and of better flavour than autumn-sown plants. No better method exists of keeping Onions than that known as roping. These ought now to be hung up in the coolest place available. I made rather an interesting experiment to test the keeping qualities during the past winter, and many of the best varieties, all treated in precisely the same way kept well, but James's Long Keeping was superior in this respect to all others.

Leeks.—The earliest sowing of these ought now to be planted in well-prepared trenches, either in single or double rows. The blanching process should be commenced immediately the plants are put out, drawing up the plant to the desired height with suitably-made paper collars. Many growers do not commence the blanching process until the plants have nearly finished growth, but in such cases the edible portion is only very short, and generally gritty. Prick out successional sowings, and sow one more small batch in the open for supplying the kitchen during late in the spring of 1909. Any old specimens should now be lifted and laid under the shade of a north wall, where they may be kept fit for use for at least another six weeks.

Seakale Beet.—This is much appreciated in many establishments when well grown. It can be easily forwarded under glass in cold frames, or pits, if the seed is sown in pots or boxes. The plants should eventually be planted out 15 inches apart all ways. Seeds may also be sown now out of doors. Prepare trenches in the same way as for Celery, and fill them three parts full with well-decayed manure, sowing one drill in each, finally thinning the plants out to 18 inches apart.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the **PUBLISHER, 41, Wellington Street, Covent Garden, W.C.**

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or communications, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.*

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, APRIL 25—
Quinquennial Exh. of the Soc. Roy. d'Agri. et de Botanique de Gand at Ghent, Belgium, lasting until May 2.

TUESDAY, APRIL 28—
Roy. Hort. Soc. Coms. meet, and Nat. Auricula Soc. combined show at Hort. Hall, Westminster. Shropshire Hort. Soc. Spring F. Sh.

WEDNESDAY, APRIL 29—
Annual Exhibition of the National Auricula and Primula Society (Midland Section), to be held at the Botanical Gardens, Edgbaston, Birmingham.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—49·0°.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, April 22* (6 P.M.): Max. 55°; Min. 42°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London—*Thursday, April 23* (10 A.M.): Bar. 29; Temp. 44°; Weather—Raining.
PROVINCES.—*Wednesday, April 22* (6 P.M.): Max. 52° Cornwall; Min. 34° Scotland N.

SALES FOR THE ENSUING WEEK.

WEDNESDAY—
Liliums, Hardy Border Plants and Bulbs, Roses, &c., at 12; Palms and Plants at 3.30, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

THURSDAY—
171 cases Japanese Liliums; also thousands of Gladiolus, Begonias, &c., and Palm seeds, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 1.

FRIDAY—
Choice Imported and Established Orchids from various sources, Orchids in flower and bud, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

Manuring in Spring.

Now that the use of artificial manures has become so common, and their action both on the plant and the soil is so well known, there is no longer any necessity for the gardener to hesitate in employing them. They have many advantages. They are very concentrated, and small dressings only are needed; they do not, therefore, render the garden unsightly, as dung would do at this season of the year. Further, they are quick in action, and the plant at once begins to feel their effect; if it really needs them, it rapidly begins to derive the benefit; they may, therefore, be applied as the necessity arises, in spring for ordinary purposes, or in summer and autumn for special purposes. Lastly, they are definite in their action, and may always be expected to produce the same general result, due allowance being made for season, &c., so that a gardener who once knows their effects may always hope to get the same results by using them. Some manures, besides benefiting the plant, also act favourably on the soil, and improve its mechanical condition.

There are five substances which act as manures, and all the host of fertilisers on the market derive their value from the fact that they contain one or more of these bodies. The five are: nitrogen compounds, phosphates, potash compounds, lime, and organic matter. The first three benefit the plant alone, the other two also improve the texture of the soil.

The general effect of nitrogenous manures is to promote vegetative growth and leaf production; they are, therefore, of special value on plants like Cabbage, Spinach, and grass, where much leaf development is wanted, and for herbaceous plants where vigorous growth is necessary. Not only do they promote leaf production in good "growing" weather, but they do so at other times as well, so that when growth has been brought to a standstill by a cold spell it may be started again by the addition of a suitable nitrogenous manure. Indeed, the inhibiting effect of low temperatures on assimilation and growth seems to be considerably modified by the addition of nitrogenous foodstuff.

Of all nitrogenous manures the quickest to act is nitrate of soda; it is, therefore, the most valuable in an emergency. Applied at the rate of 1 lb. to the rod, it is very useful when young plants are being kept back by cold weather, or showing the yellowing of the leaf characteristic of a bad condition generally. The writer has used it with advantage on young Peas checked by the cold and suffering meanwhile from the attack of slugs; it is also beneficial to young Carnations, the growth of which may have been similarly retarded. Similarly, a poor lawn may be improved by nitrate of soda; so long as the grass roots are still alive, it causes growth to start earlier and to cover up the bare places. In general, whenever an early start is wanted, either to secure greater growth or to enable the plant to grow away from some pest, a small dressing of nitrate of soda at the rate indicated above may be expected to prove beneficial. Another effect of nitrate of soda is to improve the colour of the plant. Cabbages may be greatly improved in appearance by applying two small dressings, one about five weeks, the other about two weeks, before they are to be cut; they thus get a brighter, fresher colour than they would otherwise have had. A similar improvement is effected in Spinach.

Care is necessary in applying nitrate of soda. Like other saline manures, it should not be put on to dry soil, nor should the salt get on to the young foliage. The most satisfactory way is to dissolve the pound in about two gallons of water, and to pour this solution on to the soil.

Though not quite as useful as nitrate in an emergency, sulphate of ammonia is practically equal to it for all ordinary purposes, and for some special purposes it is considered superior. Thus it is found to be better for Potatos; it increases the yield without injuriously affecting the quality. There is a common belief among Barley growers, which is probably well founded, that their crop is affected in the same way; the yield increases, but the quality does not deteriorate. Its general effect of promoting vegetative growth is sometimes of advantage to the exhibitor who wishes to keep his plants growing a little longer. Chrysanthemums and other plants, which promised to be over a few days before the show, have been kept going for the necessary time by applying a small amount dissolved in water.

As a dressing for the kitchen garden and herbaceous border, 1 lb. to the rod, applied with the precautions given above, is probably sufficient; this quantity contains somewhat more nitrogen than does a pound of nitrate of soda.

The second manurial constituent is phosphoric acid, invariably, however, combined as phospate, and nearly always as calcium phosphate. Four important fertilisers owe their value to this body—superphosphate, basic slag, bone manures, and ordinary Peruvian guano. Phosphates tend to produce a fibrous root development, and are very useful for plants like Turnips and Potatos, which depend to a large extent on a proper development of fine roots near the surface. Probably, most herbaceous plants would be found for this reason to benefit by phosphatic manures. Another valuable function is that they promote the ripening processes, so that a crop well manured with phosphates will finish sooner and ripen better than another receiving none. This is often strikingly illustrated in agricultural practice. Wheat, in the northern parts of England, dressed with phosphates, has been observed to ripen 10 days or more earlier than other Wheat in the neighbourhood which had had no such dressing. On the Rothamsted plots the Barley manured with phosphates takes on a bright golden colour, whilst the control plots are still green. Garden crops wanted to ripen early should, therefore, always be supplied with phosphates; to mention only two instances, both Tomatos and early Peas have been found to benefit considerably. Flower production also seems to be promoted by phosphates, and we find the manurial recipes favoured by successful exhibitors of Tulips, of Roses, and of Chrysanthemums. All agree in including phosphates.

On grass land they have the effect of encouraging clover, so that a lawn which originally was almost entirely grass may have its character considerably altered by one or two phosphatic dressings. This has long been known; it was observed in Cheshire a century ago, and was one of the reasons why bone manures became so exceedingly popular on pasture land; in fact, some of the less educated farmers used to allege that the clover sprang from the bones! Of course, clover is not always wanted on a lawn, but wherever it is desired, phosphatic manure will help to encourage it. On the other hand, nitrogenous manures—nitrate of soda and sulphate of ammonia—favour the grasses, so that the clovers tend to become crowded out. By taking advantage of these two facts the gardener can generally control the proportions of grass and of clover on his lawns, though, of course, sufficient time must be allowed for the crowding-out process.

Of the three phosphatic manures, superphosphate is the quickest to act, and the one most generally useful in spring and early summer; it should be applied at the rate of about 3 lbs. to the rod, all lumps to be previously broken down, so that the distribution may be fairly uniform. It may be put straight on to the soil, but should not touch the young foliage. On heavy clay land that tends to be cold, basic slag at 5 lbs. to the rod is better; by preference this should go on in autumn, but it can still be applied now. Whenever during the course of the year trenching

is being done in gardens where the subsoil is clay, it is always an advantage to dig into the bottom spit about 10 lbs. of basic slag to the rod.

Ordinary Peruvian guano at the rate of 5 or 6 lbs. to the rod is an admirable fertiliser when applied in autumn, but at this period of the year is less useful than superphosphate. Probably most gardens would benefit by the application of phosphates where these do not already enter into the scheme of manuring. Dung, the staple dressing of the horticulturist, contains an insufficient quantity, and it is usually advantageous to add a little more.

Coming now to potash, this serves several important functions, but it is less frequently necessary as a special manure, since dung contains a fair amount, and a good dressing of dung often supplies all that is needed. There are, however, certain cases where more is wanted. In some way not yet understood potash helps the plant to make the food it stores up for the next generation. For instance, it increases the store of sugar in the Sugar Beet and Mangold, and it increases the starch in the Potato and the grain of Wheat; it is, therefore, regularly applied to these crops. Another characteristic effect is that it prolongs the life of the plant. The fruit trees on the potash plots of the Wye College experimental fruit garden keep their leaves longer than the others, and a similar lengthening of life also appears to take place on some of the Rothamsted potash plots. This, perhaps, accounts for the great value of potash manures on thin, chalky, or sandy soils, where the plant tends to ripen and finish off rather too soon to admit of maximum crops. Further, potash checks rank growth, and is useful in correcting an excessive autumn dressing of dung. This is clearly demonstrated on the Rothamsted Mangold plots; where large amounts of nitrogenous manure without potash are applied, the growth is exceedingly rank, and the plants are liable to disease, but where potash is added the plants are healthy, and show an increased yield. Without potash the extra nitrogenous manure is worse than wasted; with potash it exerts its full effect. Potash is always worth trying in a garden, where the rankness of the foliage and the bad colour of the flowers indicate a disproportionately large amount of nitrogen in the soil. In fact, whenever colour of flowers or fruit needs improving, potash may be useful. Potash manuring has also been found to benefit bush fruit; its effect on grass land is often to encourage clover.

Several potash fertilisers are obtainable, but perhaps the most generally useful is the sulphate, which may be used at the rate of 3 or 4 lbs. to the rod. The muriate may also be used, but there was, and to an extent still is, a prejudice against it on account of a supposed bad effect on the quality of Potatos; the case is not definitely proved, but most gardeners would probably prefer the sulphate, with its clean record. Kainit may be more suitable where the garden is run for profit but it should go on in autumn or early spring, and cannot be applied now.

Lime and organic matter are of equal importance with the manures mentioned above, and each produces a characteristic effect shown by nothing else, but they also should be applied in the autumn.

As a general dressing for the kitchen garden or herbaceous border a mixture of 1 lb. of nitrate or sulphate of ammonia, 3 lbs. of superphosphate, and 3 lbs. of sulphate of potash may be tried. But without doubt the great advantage of artificial manures is that the gardener who has made himself acquainted with their effects can use the particular manure or manures necessary to obtain just those results he wants.

South-Eastern Agricultural College.—A meeting of the governors was held at Wye on the 13th instant, Lord Ashcombe presiding. It transpired that the establishment of professorships of agriculture and agricultural zoology in connection with London University is under consideration; members of the college staff are actively engaged in research work in mycology, soil bacteriology, animal digestion, protection of orchards from frost, and other problems of agricultural and horticultural importance.

Flowers in Season.—From Mr. W. Baylor Hartland, Ard-Cairn, Ballintemple, we have received flowers of an almost albino form of Narcissus minor, which he found in an old garden in the Ballintemple locality. N. minor (see fig. 116), the dwarf garden Daffodil, was at one time the commonest representative of the genus in gardens, and it is amongst the earliest to flower. By some authorities N. minor is placed as a variety of N. Pseudo-Narcissus. Mr. J. G. Baker, in his excellent monograph of the genus Narcissus, states that for garden purposes it may be regarded as a distinct species, but he places it with N. major, N. bicolor, and N. moschatus as a variety of N. Pseudo-Narcissus.

Fig. 116.—Narcissus minor.

Two new varieties of double-flowered Violets have been forwarded to us by Mr. Edgar Ricks, Bignell Gardens, Bicester. They were labelled Mrs. Arthur and Mrs. D'Arcy; the former is exceptionally fragrant. The flower named after Mrs. D'Arcy is of a delicate light blue colour, a very pleasing shade, and should prove an acquisition amongst these popular flowers.

Agricultural College at Cornell University.—We have received the following interesting communication from Mr. H. J. Moore, of the Cornell University, regarding the nature of the work done in the horticultural department of the Agricultural College:—"I refer chiefly to work done under glass, and shall try and confine my remarks thereto. All operations, whether experimental or otherwise, are primarily conducted for the benefit of students, and are supported by appropriations furnished by the State Legislature. At present there are two houses of about 1,000 square feet each set apart entirely for the use of graduate students to carry on experimental work, and six houses with a total area of 5,000 square feet for floriculture and the forcing of fruits and vegetables. The principal crops grown at Cornell are Tomatos, Cucumbers, Strawberries, Melons, Mushrooms, and occasionally Cauliflowers. Strawberries and Tomatos are forced on a fairly large scale in winter, and at the time of writing (March 24) we have a splendid crop of the former approaching the ripening stage. Glen Mary and Marshall are the two best varieties used for forcing here, and the berries average six or seven to the pot. We have been picking Tomatos since Christmas, and the plants at present are bearing six to eight pounds each, which is very good, considering the conditions under which they have been forced, the temperature outside falling as low as 10° to 15° below zero Fahr. on several occasions, with strong winds blowing, and as the houses are heated by steam, they cool very rapidly every time fresh coal is thrown into the furnace. The English varieties of Cucumber are not grown here at the experiment station, because commercial growers say they are of less commercial value than the American varieties, which sell much more readily, therefore, such as the White Spine varieties are grown. Turning to floriculture, the Carnation is well to the fore, and a whole house is devoted to its culture. We try both the English and American methods of cultivation, having about 200 nice plants in pots, and 500 planted out in benches. From my own observation, I think that much better results are obtained by the American or bench system, except in the case of one or two varieties. The accompanying photograph (not suitable for reproduction) shows that Carnations do fairly well here, the plants in the benches at present bearing over 5,000 blooms, with promise of more as the season advances. Since October we have cut over 1,000 blooms, and as these realise anything from 2s. to 4s. per dozen, it will readily be understood that Carnation growing is a profitable industry, especially when I say that our bench area amounts only to 262 square feet. The varieties we chiefly grow are Enchantress, Mrs. T. W. Lawson, White Lawson, Harlowarden, Robert Craig, Lady Bountiful, and this year all the new varieties, including Winsor, Imperial, Alma Ward, Mrs. C. M. Ward, and Afterglow are to be tried in order to test their relative merits, and to give students an idea of what is being done by hybridisation. All the leading varieties of Chrysanthemums are grown at Cornell. They are kept under glass all the season, and not stood out of doors as is the custom in England, the climatic conditions of Central New York State not allowing of such a procedure. Primulas, Cyclamens, Senecios, Pelargoniums, and other ornamental plants are grown, and are used both for decoration and plant-breeding purposes. Large quantities of bulbs are forced every winter, and when in flower they are arranged tastefully in one of the smaller houses, to which students have access, and where they may enjoy seeing the results of their labour. Most of the work under glass is done by students, and, speaking generally, the results compare favourably with the work done in some of the older established institutions in England. Although American horticulture is not so far advanced generally as that of the Old World, yet the matter is being taken up seriously by the State colleges, and especially by the Agricultural College at Cornell, which, under the guiding hand of Professor L. H. Bailey, has and will undoubtedly continue to set the example for operations in all things appertaining to the production of vegetables, fruits, and flowers.

Potato Scab in Salop.—According to the report on field experiments connected with the Harper Adams College in Shropshire, Potato scab has been very rampant in some land in the neighbourhood of the college. Experiments were made with various germicides, e.g., lysol, carbolic acid, and copper sulphate, but so far copper sulphate alone has proved efficacious.

Rufford Abbey Gardens. In the account of these gardens given in our last issue, p. 249, the name of the owner of Rufford Abbey was stated, by inadvertence, to be Lord John Savile, instead of Lord Savile.

"THE ROSE ANNUAL."—This little brochure of the National Rose Society is again before us. The editor is Mr. EDWARD MAWLEY, the society's energetic secretary, and this is a guarantee of the value of the contents. The little work contains many illustrations, and as it is printed on art paper they are well reproduced the pictures include portraits of the late Dean HOLE, CHAS. E. SHEA, Esq., both former presidents of the society, and E. B. LINDSELL, Esq., the president. In addition to much useful information affecting the society's business, and notices of forthcoming Rose shows, there are many short articles by well-known rosarians. A review of the society's shows of 1907 is given by the PRESIDENT, and there is an interesting critique of the great summer show at Regent's Park by Mons. TURBAT, who remarks that the blooms exhibited in the nurserymen's classes had attained a degree of perfection unknown in France. A Rose analysis for 1907, from the pen of the SECRETARY, shows that the H.T. Betsy Brown (creamy-white) is the most popular variety for exhibition purposes, followed by Mildred Grant, H.T. (ivory-white, shaded with pink), Dean Hole, and Frau Karl Druschki "Autumn-flowering Climbing Roses" forms the title of an admirable article by the Rev. J. H. PEMBERTON, and the subject is continued by Mr. GEORGE LAING PAUL. Rose-growing in Australia is described by Mr. G. W. KERSHAW, who states that a million plants are annually sold in the Commonwealth: the bulk of these are imported, and, as in the case of other garden subjects, some varieties held in esteem by Rose growers in Britain do not hold their reputation in this colony. It is gratifying to know that our packing is superior to that of Continental nurserymen, and that it is the custom of Australian importers to order all new Roses through British firms. Under the title of "Rose Jottings" are several short articles of interest to the Rose grower, including those on "Rose Mildew," "Fashions in Roses," "To Form a Rose Screen," "The Rose of the Bible," "Pruning," "Roses in Wild Woodland," &c. The concluding portion of the work gives a description of some of the newer varieties of Roses.

GINGER CULTIVATION AT JAMAICA.—In a recent issue of the *Agricultural News*, the following particulars in reference to the cultivation of Ginger at Jamaica were published from a report by the United States Consul at Kingston. The requirements for the growth of the plant are a cool, equable temperature, a regular rainfall, an elevation of over 2,000 feet, and a rich clay loam soil. It is claimed that these conditions are found in the central districts of the island, the northern central, and, to some extent, the northern parishes. No extensive acreage of Ginger, grown by any single individual, at present exists on the island, the cultivation being almost exclusively confined to settlers who possess or rent land in small areas. Since American capitalists have given such a lead to

FIG. 117.—FLOWERING SPRAYS OF NUTTALLIA CERASIFORMIS, WITH FLORAL DETAILS.

A, hermaphrodite variety; B, staminate variety.

Banana growing in Jamaica, many of the small settlers, it is said, have turned their energies in this direction, hence the falling off in the Ginger exports. Ginger is usually planted between April and June, and the crop is ready for picking between the following December and March. A Jamaican authority on the subject states that "with seasonable weather and fair attention bestowed on the cultivation, the grower may calculate upon an average of 2,000 lbs. of cured Ginger per acre."

Tamarind Seeds as Food and Medicine.—Though the Tamarind tree is well known as the source of the sub-acid fruits which, preserved in sugar, form an agreeable kind of preserve, it would scarcely be expected that the hard, bony, shining brown seeds could have any other use than perhaps for stringing as beads. In the *Agricultural Ledger*, however, Mr. David Hooper, F.L.S., of the Indian Museum, Calcutta, writing on their uses and composition, refers to their application both as a food product and for medicinal purposes. The tree (Tamarindus indicus) is a beautiful evergreen, growing to a height of 80 feet. It is considered to be of African origin, and possibly indigenous to some parts of South India. It has long been introduced into the West Indies, as well as into other tropical countries, and it is from the West Indies that we get our best and largest supplies of Tamarinds, which consists of the pulpy portion of the pod, after the removal of the epicarp or shell, but containing the fibrous part as well as the seeds. In the West Indies this is placed in barrels with syrup or sugar, the whole of which becomes amalgamated. East Indian Tamarinds are preserved without sugar; they are darker in colour and are not so agreeable to the taste as the West Indian. In medicine, Tamarinds are used as a mild laxative and refrigerant, and enter into the composition of confection of Senna. As a famine food in India, the seeds are eaten, and are prepared by first roasting and soaking them and removing the outer skin, after which they are either boiled or fried. Sometimes they are dried and ground into a flour or meal. In the uncooked state they are astringent, and are sometimes used as a poultice for boils, as well as in rheumatism. Made into a paste and applied to indolent ulcers, they have the reputation of promoting suppuration.

South African Wild Plants.—A movement has been started in Cape Colony with the object of preventing the extinction of the rarer Heaths and Bulbs which are much sought after by the professional plant collector for market purposes. The Chief Justice of Cape Colony, who is interested in the native flora and fauna, is heading the movement, and it is expected that the collection of the plants in question will be regulated by legislation.

Sale of Duncan House, Torquay.—This property, for many years the residence of the late Dr. Hamilton Ramsay, was sold by auction on the 15th inst. by Messrs. Cox & Son, Torquay, for the sum of £1,620. The late owner of Duncan House was a keen horticulturist, and his garden contained many rare and interesting plants, some of which have formed the subjects of illustrations in these pages.

Fig. 118.—Fruiting spray of Nuttallia cerasiformis (hermaphrodite variety); the diagrams show persistent calyx and a longitudinal section through drupe with seed. Natural size.

NUTTALLIA CERASIFORMIS.

This hardy deciduous shrub is known as the "Orso Berry" of California; it belongs to the natural order Rosaceæ, and is related to the Prunus, being synonymous with Prunus californica, Hort. Though not a showy shrub, it is nevertheless an attractive one, on account of its early flowers and their sweet, almond-like scent. In habit resembling the flowering Currant, the Nuttallia may be pruned and treated in the same manner as that species, as it flowers upon the young wood. In February and March the white flowers are borne in pendulous racemes before the leaves are fully expanded.

The flowers (see fig. 117) are sometimes described as polygamous, but seem to be really dioecious, the pistillate form bearing only rudimentary stamens which do not seem to be fertile. At Glasnevin one of these pistillate forms called N. c. hermaphrodita was obtained from Simon Louis Frères, Metz, and planted close to a male plant it produced fruit last year.

This dioecious or sub-dioecious character explains why fruit is seldom produced in this country, but it is only necessary to plant the two sexes together in order to obtain an abundance. The fruit (see fig. 118) is an oval-shaped drupe, about ¾ inch in length, at first yellow, then turning to purplish-blue; the fleshy part is bitter, though apparently not distasteful to birds. *C. F. Ball.*

THE "FRENCH" GARDEN.

We have now reached a period when all work is at a high pressure, and almost everything requires the attention of the cultivator at the same time. All crops are growing freely. The Carrots, which have now to be thinned out and weeded, have grown so quickly that we have had to raise the frames in which they are growing 2 inches. Previous to lifting the frames, we took care to fill up the paths between them with dry manure to prevent the soil from rolling off the beds.

The Cos Lettuces have required careful attention during the past fortnight, for the weather has been changeable and cold. It was necessary to spread the mats over the cloches when the sun was shining brightly to prevent the "hearts" from becoming soft, and also at night, whenever the thermometer fell to freezing point. This work needs care, for if the mats are placed on too early it is as harmful as if they are placed on too late. Certain growers spread the mats on the cloches when the glass is white with frost, and take them away again as soon as the frost has disappeared from the glass; this is done to make the leaves crisp—a condition much appreciated by the consumer. We have sent our first Cos Lettuce to market this week: they were planted on February 20. The cloches will be removed from the first, fourth and seventh rows, when the first forced rows are cleared. These Cos Lettuces are well established and have developed good crowns of new leaves. They will make good progress when under the cloches. Every week a few seeds of Melon are sown, in order to have a supply of plants when the beds are ready, for every spare moment is spent in making up hot-beds for these plants. This work must be hurried on so that all the frames and cloches available may be utilised for their culture by June 10. The plants of our first sowing of Melons that was made at the end of March have grown well. The plants have developed two good "breaks"; one of these growths will be directed to the top and the other trained to the bottom of the frame. The shoots have been stopped at the fourth leaf, and they will now develop side growths, upon which will be borne the female flowers. *P. Aquatias, Mayland, Essex.*

LAW NOTE.

*THE SMALL HOLDINGS AND ALLOTMENTS ACT, 1907.

MESSRS. SWEET & MAXWELL, LTD., are continuing their policy of publishing separate copies of new Acts of Parliament as they come into force (supplemented by an index, together with annotations and cross references), and we have been favoured with a copy of the Small Holdings and Allotments Act, 1907, treated in this manner. The introduction and notes are furnished by Mr. W. Hanbury Aggs, a writer who, as joint author with Mr. J. M. Lely of the well-known treatise on the law relating to Agricultural Holdings, needs no introduction to students of this subject. The work now under notice is evidently intended for the assistance of the legal practitioner rather than of the layman, its object being to supply explanatory comment on the new Act without attempting any detailed review of the subject as a whole. For this reason the absence of the earlier statutes on which the Act of last year has been grafted is perhaps not very material, as members of the profession can refer to their own copies of the earlier Acts, although the inconvenience of legislation by reference to previous statutes thus becomes especially apparent. For this inconvenience, Parliamentary practice, and not the author, must be blamed, but as soon as the pending Consolidation Act becomes law, a reprint, coupled with notes by the same writer, should prove of even greater value. Meanwhile, it may be observed that the introductory explanation to the present Act is generally clear and concise, though we confess we do not quite follow the author's line of reasoning when he states: "The obligation upon the County Council is only to provide small holdings for persons who desire to buy or lease, and will themselves cultivate the land: consequently, the application of a person who had had no previous experience in cultivation would probably not be acceded to." The author rightly points out that in the case of small holdings, an applicant need not necessarily be a ratepayer or resident in the county, whereas, in the case of allotments, those can only be let to persons belonging to the labouring population resident in the district or parish. At the same time it appears to us that evasion of the latter provision presents no great difficulty, unless the councils should fix a minimum period of residence prior to application. We venture to disagree with the learned author when he suggests that in forwarding an application to the County Council, or the Parish Council as the case may be, a copy of the application should also be sent to the Board of Agriculture and Fisheries, in order that it may reach the hands of the Small Holdings Commissioners. In a previous issue, we have advised applicants to communicate with the Small Holdings Commissioners only in the event of their application meeting with an unsatisfactory response from the council, and this we think is the better course from the practical point of view. Official susceptibilities have to be considered, and probably the clerks to some of the councils might not altogether appreciate the Small Holdings Commissioners being brought into the matter by an applicant before the councils themselves had considered the application. One misses also the customary warning as to the difference between the powers of purchase vested in the council according to whether it is proposed only to let land on lease or whether it is intended to sell to an applicant outright.

These few comments, however, are not intended to detract from the undeniable utility of the general explanation, together with the annotations and cross references, as a whole. Those desiring to form an association for the purpose of creating, or promoting the creation of, small holdings would do well to note the author's reminder that a limited company (formed for this purpose under the Companies Acts) without the addition of the word "Limited" to its name cannot hold more than 2 acres of land without the licence of the Board of Trade.

* The Small Holdings and Allotments Act, 1907, with Notes, Index, and an Introduction by W. Hanbury Aggs, M.A., LL.M., Barrister-at-Law of the Inner Temple (Sweet & Maxwell, Ltd., and Stevens & Sons, Ltd.)

NEW INVENTIONS.

A SELF-WATERING FLOWER BOX.

FLORISTS generally will be interested in the self-watering flower box which the Illinois Heater and Manufacturing Company, 3946, Wentworth Avenue, Chicago, are offering. As the name implies, the box is provided with a self-watering device, which renders attention unnecessary, except at intervals of from 10 to 20 days, according to the size of box and atmospheric conditions prevailing during the periods named. The box is made of heavy galvanised iron, pressed and corrugated at the seams, and so carefully soldered that leakage is absolutely impossible—a fact which makes the box very desirable for use in the windows of flat buildings and apartment houses, doing away with the usual objections emanating from owners. The top edges are made extra strong by forming them in the shape of a hollow square, and then reinforcing the corners by a patented device. The box for window use is made with the front sloping outward and the back straight, so that it may be accommodated on any ordinary window sill, and a window screen may be raised or lowered without disturbance. It is provided with heavy brass eyelets, for easy and secure attachment in a required position. The box is finished in a hard and durable enamel of dark green, but is finished in any other colour when specially ordered, at a slight extra cost.

The operation is simple. A metal tube in the corner of a box extends from a water reservoir in the bottom upward through the soil to the top of the box. Through this tube water is poured into the reservoir underneath a false bottom which supports the soil. Inserted in holes in the false bottom are sponges which touch the extreme bottom of the box and extend upward into the soil in which the flowers are planted. The water is drawn upward through these sponges in sufficient quantities to maintain a uniform moisture in the soil, and at the same time sufficient air is supplied with the water to insure to the plants a thrifty and healthy growth.

The box has been in use in different parts of the country for a season or two, and a large and growing business has already been built up. It has been the experience of users that the soil surface never becomes hardened or baked in the slightest degree, and in the construction of the box is a perfect application of the principle and advantage of sub-irrigation.

The box is made in a variety of sizes for window use, and is also made in styles suitable for porches and cemetery purposes. Hanging baskets, flower pots and jardiniere pans are also made embodying the same principles. The boxes are seasonable articles just now, and florists are recommended to write for the illustrated catalogue which the makers are sending out. *The Florists' Review (American), March 21, 1908.*

A TREE MEASURER AND FLOWER-POT ENVELOPE.

MESSRS. WM. WOOD & SONS, the well-known horticultural sundriesmen, of Wood Green, London, send us particulars of a new instrument for ascertaining the height of trees, also an envelope for retaining the moisture in plant pots. The tree measurer is termed the apomecometer, and consists of a small drum-like instrument, the height being taken by means of openings in the side, through the largest of which the top of the tree is reflected and brought on a level with a point previously determined near the base. The measurement from that position to the bottom of the tree, plus the height of the distinctive mark, gives the total height of the tree.

THE FLOWER-POT ENVELOPE is formed of a water-holding matting, mainly constructed of straw. The envelopes are moistened when the plants are watered, and it is claimed that, by this means, the roots are kept moist in hot weather for a longer period than without their use. They appear to be similar in structure to the straw cases in which wine bottles are often placed.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

YORKSHIRE GARDENERS AND THE ROYAL GARDENERS' ORPHAN FUND.—This fund and the special appeal which is being made at the present time on its behalf in connection with the coming-of-age festival on May 12 should, I think, be of especial interest to Yorkshire horticulturists, seeing that the inception of the fund was mainly due to a Yorkshire gardener, Mr. Clayton, late of Grimston Park, but probably many, like myself, have hitherto never given the matter any very serious thought, or it may be that we are sometimes apt to think that such institutions, having their headquarters so far away as London, have not much claim upon us here in the North. A glance, however, through the annual report certainly shows that this is not the case. I find that there are in Yorkshire five children in receipt of the benefits of the fund, viz., £13 per annum each, or £65 in all, but the whole of the subscriptions from Yorkshire fall very much below this amount, and the proportion of it which comes from Yorkshire gardeners is very small indeed. I note that one town in the Midlands (not a large one) sends half as much as the whole of Yorkshire. An appeal made during the past week to three small gatherings of gardeners in this locality had an immediate result of nearly 50 shillings being subscribed to the popular shilling collection, and several volunteered to take collecting sheets for their respective districts, so that I hope this amount will be considerably increased before the coming-of-age festival on May 12. May I suggest to gardeners in other parts of the country that, if the matter has not already been taken in hand, some such plan should be adopted, as the result, I am sure, would be a a birthday gift worthy of Yorkshire and Yorkshire gardeners, and would probably arouse an interest which would also have the effect of increasing in future the number of annual subscribers to this worthy object. Gardeners living in a district where no collection is being made, who would like to contribute, and so swell the amount from Yorkshire, are asked to send their subscriptions to Mr. Norman, The Elms, Weetwood, Leeds; Mr. Coates, Spring Bank, Headingley, Leeds; Mr. Wellwood, Wyther House, Kirkstall, Leeds; Mr. Waltham, Landy Wood, Horsforth, near Leeds; or to myself. *George Carter, Chapel-Allerton, Leeds.*

THE WEATHER AT BERKSWELL.—I do not think I can recall such a cold, inhospitable March as the one just passed; and April, up to the present time, is not much of an improvement. We are experiencing cold east winds, with frequent showers of large snowflakes and hail. The cold, however, is not an unmitigated evil—it prevents vegetation from becoming too forward; fruit buds of all kinds are exceedingly plump and promising, and if the weather is genial when the fruits are setting we shall probably have abundant crops of fruit of all kinds. We read in Scandinavian mythology that in the garden of one Bragi there grew an Apple tree which produced Golden Pippins. These Pippins were carried about in a basket by Iduna, who was wife to Bragi, to whom she gave a fruit, and they did eat; they had a renewal of their youth, and in this way lived to a very great age, and no matter how many Apples were given away, their number never grew less. I have often thought that in these times when we have difficulty in growing fruit in this country, someone ought to go into Scandinavia on the off-chance of finding this most wonderful and valuable tree. Apart from the quality of the Pippins, of which I cannot speak, the virtue of the renewal of youth would be much appreciated by tottering, aged horticulturists and others in this country. I have (April 21) neither seen nor heard of the arrival of any of the migratory birds. The cold, stormy weather may have been partly the cause of their absence. They are wise in stopping away, for there are no insects about on which they could live. I have been feeding tom-tits at my window all the winter; they became very tame, and would come close up to the window and look in, soliciting in the most gentle and mannerly way for a few crumbs. *W. Miller, Berkswell.*

Horticultural Hygrometer.—An illustration and notice of this invention in the *Gardeners' Chronicle* last autumn induced the purchase of one for these gardens. It is an instrument for ascertaining the likelihood of a frost during the coming night. "The dew-point determines the minimum temperature of the night," and, as the makers of the hygrometer state, it is only fair to presume that if the dew-point is below freezing point there will be a frost during the night. The value of reliable information on this all-important subject is obvious. Nothing in this world is infallible, and the makers of the hygrometer do not advertise that their instrument will forecast a frost with mathematical exactitude, but that it shows the *likelihood* of a frost, and after a thorough trial I am satisfied that it does this, and look upon the hygrometer as an indispensable adjunct of the garden. Twice during the past week there were no apparent signs of frost at dusk—on each occasion the temperature was over 40° Fahr., but the hygrometer indicated probable frosts, and frosts there were (10° and 8°). The manipulation of the instrument is exceedingly simple, and there is nothing to get out of order. It is important that the observations be taken as late in the evening as possible. Its greatest value to the gardener will be during the next eight or ten weeks. I have found it a good plan to divide the shaded portion of the cylinder into two equal parts, and term the lower half "frost probable." *A. C. Bartlett, Pencarrow Gardens.*

Mealy Bug on Vines.—There is nothing new in the use of cyanide gas for the destruction of insect pests, but the risk to the operator is great and many gardeners have been deterred from using it. With the aid of the cyaniding machine referred to on p. 238, the fumigation can be carried out with safety, provided the house is kept locked and that cards or notices are affixed to the doors stating that the house contains a poisonous gas. The reason why cyanide of potassium is so largely used in preference to cyanide of sodium is that it is easily procurable from any chemist, but the sodium cyanide is much stronger, the strength being 130 compared to 98. The Board of Agriculture have recently issued a leaflet (No. 188) on the use of this gas. This leaflet may be obtained post free from the secretary, Whitehall Place, London, S.W. It states that the vessel containing the acid and water should be placed near the door, but the only successful way to use it is to have several vessels in the house, and this can be accomplished by the use of the machine referred to. *John Donoghue, Bardon Hill Gardens, Leeds.*

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

April 14.—*Present:* Mr. E. A. Bowles, M.A., F.L.S., F.E.S. (in the chair); Messrs. G. S. Saunders, W. Hales, E. M. Holmes, A. Worsley, W. C. Worsdell, G. Massee, J. T. Bennett-Pöe, W. Cuthbertson, and F. J. Chittenden (secretary).

Funnel-shaped outgrowth in Ivy.—Mr. W. C. Worsdell showed a leaf of Ivy having a funnel-shaped growth proceeding from near the base, similar to that often seen in Cabbages, but in this case it grew from the lower surface.

Double-spathed Richardia.—G. Siggs, Esq., Streatham Hill, sent an inflorescence of Richardia æthiopica with a second full-sized leaf proceeding from the flowering stem.

Potato-disease fungi.—Mr. Massee showed specimens of Potato tubers affected with "winter rot," with the fungus Nectria solani, which is the cause of the disease, growing thereon, remarking that it had been particularly prevalent during the past season, a fact that he attributed partly to the prevalence of rain during the last summer, and the difficulty of thoroughly drying the tubers before they were stored. This fungus had recently, he said, been described under another name by an investigator, a condition of things found not alone in this disease, for recently the fungus long ago described by Berkeley (see *Journ. Roy. Hort. Soc.*, Vol. I., 1846, p. 33, figs. 30, 31) under the name of Tubercinia scabies, and now known as Sorosporium scabies, Fisch., one of the causes of Potato scab, had been apparently rediscovered and renamed as new, Spongospora solani on the Continent, and this name had been taken up by some botanists in England and Ireland as the newly-discovered cause of Potato scab.

Propagation of Drosera.—Mr. Hales showed plants of Drosera hilaris raised from root cuttings put in about five weeks ago. The plants had each developed a number of leaves.

Hybrid Orchids.—R. G. Thwaites, Esq., Streatham Hill, S.W., wrote in reference to the communications recently received by the Committee concerning the crossing of albino Orchids: "The result of crossing Dendrobium Wiganianum album (in which the peduncle is only slightly coloured) with D. nobile virginale (which is white all through) has been, in every instance, a coloured flower of the ordinary D. nobile type; whilst D. nobile virginale self-fertilised has in every instance produced pure white flowers, appearing to prove that D. Wiganianum album is not a true albino. Again, when D. nobile virginale is crossed with D. aureum in every instance the same result is obtained as from crossing the ordinary D. nobile with D. aureum, namely, D. Ainsworthii, the flowers of which are full of colour."

Gall-like growths of Larch.—Mr. Massee reported that the gall-like growths on the Larch shoot recently shown by Mr. Elwes were really the scales of a female cone, which had been separated from one another by the growth of internodes. They had apparently been early attacked by Thrips abietis. Seed and seed scales were both to be found in their axils.

Seedling Elm.—Mr. Chittenden showed a seedling of Ulmus glabra from Terling, where they had occurred in abundance last season (see *Kew Bulletin*, 10, 1907, p. 404). This Elm is abundant in many parts of Essex, but only once before had he found a seedling, and that in his garden at Chelmsford in 1903. U. campestris, of which this is probably a form, is not known to seed in England, unless the seedlings recorded from the King's College "Backs" should prove to be really those of that tree.

ROYAL BOTANIC.

April 22.—The flower show held on this date under the auspices of the above society was of small extent. The showiest exhibit was composed of Cinerarias from the gardens of Edward Wagg, Esq., The Islet, Maidenhead (gr. Mr. D. Phillips). Some of the florets measured 1½ inches in length. The foliage was ample, and was finely contrasted with a border line of Adiantum Ferns. (Gold Medal.)

Daffodils and Narcissus varieties formed a considerable portion of the display. H. R. Darlington, Esq., Park House, Potters Bar (gr. Mr. D. Bignell), made an exhibit of these seasonable flowers, especially fine being Glory of Leyden, Horsfieldii, Golden Bell, Victoria, Maximus, Madame Plemp, and Stella superba.

The Misses Curry, Lismore, were exhibitors of a larger collection than the foregoing. Very nice flowers were Weardale Perfection, Lemon-drop, Vanity (a beautiful flower of the Poeticus section), Enid (white trumpet), Blood Orange, Lucifer, Firebrand, Albatross, Glory of Leyden (a fine flower), and Argent (a flower with a creamy perianth and bright yellow corona). (Silver-Gilt Medal.)

Messrs. Barr & Sons, King Street, Covent Garden, London, made a display of moderate extent, which contained many of the hand-some varieties of Narcissi. Of these mention may be made of Barrii Sensation, Barrii conspicua, Katherine Spurrell, C. J. Backhouse, Frank Miles, Calpurnia, &c. (Silver-Gilt Medal.)

An interesting display of greenhouse and forced hardy plants was made by Messrs. W. Cutbush & Sons, Highgate, and Barnet. There were Roses, Erica ventricosa magnifica, Boronia heterophylla, small bushes of Oranges, Spiræa, Peach-blossom, Azaleas, &c. (Large Silver-Gilt Medal.)

Edward Wagg, Esq., showed a small group of Hippeastrums.

Messrs. Thos. Ware, Ltd., Feltham, showed Dendromecon rigidum, Satyrium coriifolium, the golden variegated-leaved London Pride (Saxifraga umbrosa), Primula Croussei, Conandron ramondioides, and other rock-garden plants. (Silver-Gilt Medal.)

A bright group of Narcissi, Tulips, and Anemones of the St. Brigid varieties was shown by Messrs. Hogg & Robertson, 22, Mary Street, Dublin. Of Narcissus we may mention the varieties Dorothy Yorke, Lorenzo, Autocrat, Lady Arnott, Maggie May, Mrs. G. F. Brooke, John Bain, and General Murray, varieties of pleasing colour and form, good for grouping and cutting. The Tulips were distinguished by their size of bloom and general vigour. (Large Silver-Gilt Medal.)

Messrs. John Peed & Son, West Norwood, showed a considerable number of rock and Alpine plants in pots sunk in boxes filled with cocoanut-fibre. (Silver Medal.)

BRITISH GARDENERS' ASSOCIATION.

LONDON BRANCH.

April 9.—The first meeting of the recently formed London branch of this association was held on the above date, when there was an attendance of about 50 members and other gardeners.

At 8 p.m. Mr. E. F. Hawes delivered an exhaustive address on "The present opportunities for improving Gardeners' Education in London." After reading the objects of the association, in which "the encouragement of a higher state of efficiency" is set forth prominently, the lecturer said that London offered many advantages to young men seeking to improve their knowledge of horticulture, which could not be secured in country districts. First of all, there are the numerous well-kept public parks and gardens, from which many useful lessons can be learned. Mr. Hawes stated that the late Mr. Jordan, of Hyde Park, undertook long tours through provincial and continental parks for the purposes of comparing them with our London parks, and to gather knowledge.

The great exhibitions in London formed another source of instruction. The fortnightly meetings of the R.H.S. were invariably full of interest, and much up-to-date knowledge could be gained by attending them. The exhibitions of the Royal Botanic Society, the National Chrysanthemum Society, the National Rose Society, together with the Dahlia, Carnation, and other special organisations were also instanced in this connection.

The various evening classes on scientific subjects connected with horticulture, provided by the London, Middlesex, Surrey, and Kent County Councils were of the utmost value to the young gardener. Practice should be combined with science, and practice given the first place. Freehand drawing and a knowledge of arithmetic were desirable qualifications for positions of importance.

Mr. Thomas Winter is announced to give a lecture on "Public Gardens and their Construction" at the meeting to be held on May 14.

April 14.—At the meeting of the Executive Committee, held on the above date, 24 new members were elected, bringing the total up to 1,211. The secretary was deputed to address a meeting at Blackburn on the 15th inst. The draft report of the annual meeting was considered and amended, as was also the report of the Sub-Committee on Examinations. A reference to the conditions of employment at Kew was made, and will be considered by the Executive Council.

NEW BRANCH AT BLACKBURN.

On Wednesday, April 15, a meeting of gardeners of the Blackburn district was held under the chairmanship of Mr. Stradford, superintendent of the Corporation parks, for the purpose of forming a local branch of the B.G.A. The chairman was supported by Mr. Batty, gardener at the Corporation Cemetery; Mr. Hudson, superintendent of Queen's Park; Messrs. Boyd, Pimlott, Marshall, Winter, Bradburn, Murray, and about 60 other gardeners. Mr. J. Weathers, general secretary, delivered an address upon the work, aims, and objects of the association. After numerous questions had been put and answered, it was decided to form a Blackburn branch of the association, and about 60 persons gave in their names for membership. Mr. Stradford was elected chairman, and Mr. Batty, secretary, of the new branch. The committee will be appointed at a subsequent meeting.

ROYAL CALEDONIAN.

SPRING FLOWER SHOW.

April 15, 16.—The spring show of the above society, held in the Waverley Market, Edinburgh, on these days, was affected by the change of dates from those originally selected and by the backward season. The attendance of the public was small, and there was a diminution in the number of large trade exhibits usually seen at these displays. Amongst the best of the exhibits were the displays of Roses, both pot plants and cut blooms.

In the competitive classes, an outstanding feature was a display of Orchids staged by Mr. W. Sharp, Freelands, Forgandenny. Mr. Sharp was awarded the 1st prize; 2nd, Mr. D. Mackay, Viewbank, Lasswade. In the class for a group of miscellaneous plants arranged in a space measuring 20 feet by 12 feet, Mr. A. Knight, Braton, Carlisle, won the 1st prize; 2nd, Mr. G. Wood, Oswald House, Edinburgh.

Other prominent exhibitors in the classes for plants were Messrs. D. Kidd, Carberry Tower, Musselburgh; A. McMillan, Douglas Castle, Lanark; R. Davidson, Kinloch Castle, Rhum; G. McKinna, Norton Park, Ratho; and J. Pearson, Beechwood, Edinburgh. The best display of Alpines was staged by Mr. W. G. Pirie, Dalhousie Castle, Bonnyrig. Mr. A. Johnston, Hay Lodge, Edinburgh, showed the best Ferns, and Mr. J. Thom, Carlowrie, Kirkliston, was the most successful exhibitor of Roses.

In the cut flower section an important class was that for a decorated dinner table; Mr. Davis, Ballathie, Stanley, was awarded the 1st prize; 2nd, Mr. Kidd, Carberry Tower Gardens.

In the competition confined to under gardeners for a plan for laying out a piece of ground 8 acres in extent, the prizes were awarded as follows:—1st, Mr. W. Forsyth, Durris, Drumoak; 2nd, Mr. D. T. McKinlay, Palace Gardens, Dalkeith; 3rd, Mr. J. M. Webster, Bothwell Castle Gardens, Bothwell.

Non-competitive displays were interesting. Exhibits of Daffodils were shown by Messrs. Barr & Sons, Covent Garden, London (Gold Medal); Hogg & Robertson, Dublin (Silver-Gilt Medal); and the Lissadel Bulb Farm, Sligo (Silver-Gilt Medal). Messrs. R. B. Laird & Sons, Ltd., Edinburgh, showed forced plants in an attractive manner (Gold Medal). Messrs. Cunningham, Fraser & Co., Edinburgh, had a fine show of forced hardy Rhododendrons in addition to an exhibit of rock-garden plants (Gold Medal). Messrs. W. Cutbush & Son, London, staged flowering shrubs, Carnations, and a new Coleus named "Cordelia" (Gold Medal). Mr. John Forbes, Hawick, had a collection of Violas, Pansies, Primulas, Carnations, &c. (Silver Medal). Mr. John Downie, Edinburgh, exhibited Astilbe (Spiræas) in variety (Silver Medal). Messrs. Dobbie & Co., Rothesay, showed Primroses, Pansies, and Violas (Bronze Medal). Orchids were finely shown by Mr. McLeod, Chorlton-cum-Hardy, and Messrs. A. J. Keeling & Sons, Westgate Hill, Bradford. An improved strain of Primula obconica was displayed by Messrs. Storrie & Storrie, Glencarse, Perthshire (Bronze Medal). Mr. G. Roche, Gowran Castle, Kilkenny, had a fine exhibit of St. Brigid Anemones (Bronze Medal). Messrs. Hugh Low & Sons, London, displayed vases of Carnations.

Narcissi Bedouin and Charm, exhibited by Messrs. Barr & Sons, received First Class Certificates, and a new hybrid Primula, P. × Angusii, exhibited by Mr. W. Angus, Penicuik, received an Award of Merit.

ROYAL METEOROLOGICAL.

April 15.—The monthly meeting of this society was held on the above date, at the Institution of Civil Engineers, Great George Street, Westminster, Dr. H. R. Mill, president, in the chair.

Mr. Edward Mawley presented his "Report on the Phenological Observations for 1907." He pointed out that the most noteworthy features of the weather as affecting vegetation were the cold and sunless character of April, May, and the three summer months, the frequent falls of rain during that period, the warm, dry, and sunny weather in September, and the heavy and continuous rainfall in October. Wild plants came into blossom behind their usual dates throughout the whole of the flowering season. Such early immigrants as the swallow, cuckoo, and nightingale were also behind their average dates in reaching these islands. The only deficient farm crop taking the country, as a whole, was that of Potatos, most of the other crops being much over average. On the other hand, the yield of Apples and Pears, and particularly that of the former, was below average. There was also a deficient crop of Strawberries, whereas Plums, Raspberries, Currants, and Gooseberries were over average. As regards the farm crops, Mr. Mawley stated that 1905 was a plentiful year, in 1906 the yield was even better, while the past year proved the most bountiful of the three.

Colonel H. E. Rawson, C.B., R.E., read a paper on "The Anti-cyclonic Belt of the Southern Hemisphere."

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

April 13.—The quarterly meeting of this society was held at the Horticultural Hall, Vincent Square, Westminster, on the above date. Mr. Charles H. Curtis occupied the chair. Five new members were elected, making a total of thirty for the quarter. Sickness has been heavy, but rather less than during the first three months of 1907. Members more than 60 years of age are allowed to withdraw the interest on their deposit account; several avail themselves of this privilege, and utilise the money for the payment of their subscriptions. The rules of the society may be obtained from the secretary, Mr. W. Collins, 9, Martindale Road, Balham, S.W.

DEVON & EXETER HORTICULTURAL.

April 10.—This, one of the oldest horticultural societies in the country, held its 206th consecutive exhibition on this date, the exhibition being mainly one of Daffodils. As a first effort in this direction it was creditable, but from lack of funds, and the consequent inability to offer tempting prizes, the competitors were purely local and very few in number. In this respect the show was disappointing, for in many of the classes there was no competition, and in others only two, the judges in several cases withholding the first prize and awarding a second only. There were, however, several excellent trade exhibitions staged by Messrs. Robert Veitch & Son, of Exeter; Messrs. Barr & Sons, King Street, Covent Garden, London; Messrs. W. Cutbush & Son, Highgate, London; W. J. Godfrey, Exmouth, and Sir Josslyn Gore-Booth, of Lissadel, Sligo, all of whom staged interesting and valuable collections of shrubs, plants, and Narcissi.

In the competitive classes, the principal prize-winner was Mr. W. Brock, of Exeter (gr. Mr. Rowland), but the winner of the prize offered for the best 24 Daffodils was Mrs. Gage-Hodge, of Rewe, near Exeter.

Roses in pots were well shown by Mr. C. M. Collingwood, Exeter; well-cultivated Cyclamen were exhibited by Mr. Luxmore Jones, Exeter, and the Rev. G. E. Heathcote, Rewe; good Azaleas and Cinerarias were displayed by Mr. Brock. *A. H.*

COMMONS AND FOOTPATHS PRESERVATION.

At a recent meeting of the Commons and Footpaths Preservation Society, the proposal of the War Office to conduct manœuvres on a large scale in the New Forest during the coming summer was considered. It was pointed out that the Military Manœuvres Act, 1897, was passed to facilitate, under proper safeguards, the holding of manœuvres, and that it contained special provisions regulating the use of the Forest for military purposes. The War Office, however, now claimed that it could ignore the Military Manœuvres Act, since it had received the consent of the Office of Woods and Forests, representing the Crown, to the proposed manœuvres. Strong exception was taken to this contention, and it was decided to co-operate with the verderers, commoners, and others interested in making further representations to Mr. Haldane, and in taking such other action as might be necessary to secure that due regard should be had to the protection of public interests under the Military Manœuvres Act.

It was also decided to urge the President of the Local Government Board to amend Section 7 of the Housing and Town Planning Bill, now before Parliament. Under the Bill as drawn local authorities would have power to alienate open spaces committed to their care for the purpose of providing sites for dwellings for the working classes, and it was resolved to press that common land or land dedicated to the recreation of the public should be exempted from the operation of the clause. It was reported that the Board of Agriculture had now issued draft schemes for the regulation under the Commons Act, 1876, of Towyn Trewan Common, Anglesey, 1,300 acres in extent, and Maidenhead Thicket and Cookham Commons.

It was stated that the litigation with regard to a large and valuable driftway crossing Marsden Moor, Yorks, had terminated in favour of the public, and that up to the present subscriptions and guarantees amounting to £1,552 had been received towards £1,800 needed to secure the purchase of Ludshott common and a strip of land adjoining Waggoners Wells, situate near Haslemere, and embracing 560 acres of moorland and sylvan scenery. It was decided to make representations to the Postmaster-General with regard to the disfigurement of Epping Forest by unsightly lines of telephone poles.

THE WEATHER.

THE WEATHER IN WEST HERTS.

Week ending April 22.

A deep fall of snow for April.—The first day of the week was moderately warm, but since then very low temperatures have prevailed. On the coldest day, Easter Monday, the temperature in the thermometer screen did not rise above 44°, which is about 12° colder than is usual in the latter half of April. On five successive nights the exposed thermometer registered from 4° to 10° of frost. The ground temperatures have consequently fallen, and are now 2° colder at 2 feet deep, and 4° colder at 1 foot deep, than is seasonable. Rain, hail or snow fell on four days, but to the total depth of only about a quarter of an inch. After one of the snow showers on Easter Monday the ground was covered to the average depth of rather more than an inch. This covering of snow had, however, entirely disappeared in less than an hour. The only previous instance of snow covering the ground to any measurable depth in the month of April during the last 21 years was on April 7, 1905, when it also lay to the depth of an inch. The percolation through the soil gauges was very slight during the week. The sun shone on an average for 6¾ hours a day, or for 1¼ hour a day longer than is usual at this period in April. On the sunniest day the sun was shining brightly for over 11 hours. Light airs as a rule prevailed, and the direction was always some northerly point of the compass. The mean amount of moisture in the air at 3 p.m. exceeded a seasonable quantity for that hour by 8 per cent. *E. M., Berkhamsted, April 22, 1908.*

GARDENING APPOINTMENTS.

[*Correspondents are requested to* ***write the names of persons and places as legibly as possible.*** *No charge is made for these announcements, but if a small contribution is sent, to be placed in our collecting Box for the Gardeners' Orphan Fund, it will be thankfully received, and an acknowledgment made in these columns.*]

Mr. R. Mason, for the past 4 years and 8 months Foreman at Longford Castle Gardens, Salisbury, Wilts, as Gardener to the Rt. Hon. Viscount Galway, Serlby Hall, Bawtry, Yorks. (Thanks for contribution to R.G.O.F.)

Mr. P. J. Barham, for the past 8¼ years Gardener to Col. Wm. Hall Walker, M.P., Gaiacre Grange, Liverpool, as Gardener to Leigh Goldie Taubman, Esq., The Nunnery, Douglas, Isle of Man.

Mr. Stephen Preston, for the past 9½ years Gardener to J. Harriman, Esq., J.P., Fernside, Shepshed, as Gardener to E. M. P. de Lisle, Esq., Garendon Park, Loughborough, Leicestershire.

Mr. J. R. Eastwood, for the past 18 months Gardener to The Hon. Edith Cunliffe-Lister, Patrick Brompton, Bedale, as Gardener to Colonel Parker, Brownholme Hall, Clitheroe, Lancashire. (Thanks for a donation of 1s. for the R.G.O.F. box.)

Mr. C. Evans, for the past 5 years Foreman at King's Bromley Manor Gardens, Lichfield, as Gardener to the Rev. Custance, Lowington, Burton-on-Trent.

Mr. A. F. Jones, for 2 years Foreman at Derry Ormond Park, Cardiganshire, the residence of W. Inglis-Jones, Esq., as Gardener to E. B. Compton, Esq., Monachty, Cilan Aeron, Cardiganshire.

Mr. W. H. Massam, for the past 3 years Gardener to Sir Owen Roberts, Plas Dinas, Carnarvon, as Gardener to R. Gerrish, Esq., Milford Manor, Salisbury, Wilts.

Mr. A. Simeson, for the past 5 years Gardener at The Pastures, Derby, as Gardener to E. Heseltine, Esq., The Goldings, Great Warley, Essex. (Thanks for your contribution of 2s. to the R.G.O.F.)

MARKETS.

COVENT GARDEN, *April 22.*

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—Ed.]

Cut Flowers, &c.: Average Wholesale Prices.

— (Teneriffe), per bundle of four boxes	8 0	18 0

Remarks.—Mushrooms are inclined to be firm in price owing to a shortage caused by the cold weather, best "Broilers" are selling for as much as 10d. to 1s. per lb. Supplies of English Tomatos do not seem to increase, largely owing, no doubt, to the cold weather. Chicory was in great demand on Tuesday last for the principal consignments had not arrived when the market was opened. Good prices were made by the salesmen who had supplies on hand, 2d. to 7d. being the average price paid for this vegetable on Tuesday morning; best samples to be obtained to-day (Wednesday) at 3d. and 5d. English Beans are inclined to be firmer this week, although up to the present time no advance in their prices has been made. The fruit trade in general is quiet, as is also business in vegetables. *E. H. R., Covent Garden, Wednesday, April 22, 1908.*

Remarks.—Supplies are still limited and the trade still continues firm, but not quite so good as the previous week. *E. J. Newborn, Covent Garden and St. Pancras, April 22, 1908.*

COVENT GARDEN FLOWER MARKET.

The Saturday before Easter is always the busiest morning in the year for the cut flower trade, and last Saturday was no exception. The market was crowded with persons many of whom were sightseers. Although supplies were very large, the salesmen were asking high prices early in the morning, and flowers purchased for dispatch by early trains were much dearer than those bought later in the day. Lucharis appeared to be the only flowers that were not procurable. Callas realised 6s. per dozen at the opening of the market, but their value dropped later to 4s., and there was about the same difference in the prices of Lilium longiflorum. A few of these latter flowers were sold at 6s. to 7s. per bunch, but they averaged from 4s. to 5s. L. candidum made prices almost equal to the last named. L. lancifolium sold well. Lily of the Valley was very plentiful, and did not advance in prices to any great extent. There were large supplies of white Azaleas and Roses. This morning (Wednesday) Roses were selling freely, as many buyers were preparing for St. George's Day. Among Carnations are fine blooms of Francee, Windsor, Britannia, Robt Craig, and crimson and white kinds, of best quality, but all are over plentiful. Supplies of Daffodils are excessive, the varieties Madame de Graaff, double Phœnix in several shades, Mrs. Langtry, Horsfieldii, Sir Watkin, and others are all good. Statice latifolia, in blue, white, and yellow flowers, is already seen. White and pink Gypsophila elegans is abundant.

Pot Plants.

Rambler Roses are prominent, large specimens of Hiawatha, Lady Gay, Cant's Blush, and Crimson Rambler are well flowered. The dwarf Madame N. Levavasseur is very good, but the hybrid perpetuals are not of the best quality. Ivy-leaved Pelargoniums include well-flowered plants of Galilee in 48's pots, these make about 8s. per dozen. Madame Crousse in 60's are well-flowered. Rhodanthe is seen, but it requires a few days' sun for the flowers to be at their best. Spiræas are sold at reduced prices. Marguerites have been selling better. Stocks have a poor demand, but a few days warm weather will see a larger sale for them, and this also applies to other plants used for furnishing window-boxes. Zonal Pelargoniums are good in several of the most useful sorts. Mignonette is remarkably good from several growers. Lilium longiflorum may be had in plants of various heights from 1½ to 3 feet. Hydrangeas are plentiful in all sizes. Cyclamen are still procurable. Gemstas are plentiful but the flowers of some are far advanced. Supplies of Daffodils and Hyacinths hold out. Ericas are fairly abundant. Foliage plants are well supplied. Amongst Ferns I noticed good plants of Nephrolepis Todeoides in 48's pots; they were offered at 24s. per dozen.

Bedding Plants, &c.

Growers are sending in large supplies of all kinds of summer bedding plants, but the cold weather has militated against their sale. Amongst them are seen Dahlias, also Zonal Pelargoniums, Calceolarias, Lobelia, Coleus and other tender plants. The growers of hardy flower roots have large stocks on hand, which, if the weather had been favourable, would have been cleared weeks ago. *A. H., Covent Garden, Wednesday, April 22, 1908.*

TRADE NOTICES.

LIMITED COMPANIES.

Messrs. George Fowler Lee & Co., Ltd.—This company has been formed with a capital of £5,000 in £1 shares. The objects are to acquire the business carried on at Maidstone, under the name of Fowler Lee & Co., and to trade as fruit and vegetable growers, preservers merchants, &c. No initial public issue. Registered office, 70, 70a and 72, Queen's Road, Reading.

Messrs. W. Baldock, Ltd This company has been registered with a capital of £2,000 in £1 shares. The objects are to acquire the business carried on at Brighton and Portslade as W. Baldock, and to carry on the business of fruit, plant and flower growers and salesmen, nurserymen, gardeners, floriculturists, fruit and vegetable preservers, &c. There is no initial public issue, and the company has been registered without articles of association. Registered office, 19, Prince Albert Street, Brighton.

ENQUIRIES AND REPLIES.

MOTOR LAWN MOWERS.—In reply to Mr. Maiden's enquiry on page 224, I may say that we have used a 30-inch motor lawn mower in place of a 36-inch horse mower, and the former machine has proved to be very much the better implement. Not only has it done a much greater amount of work, but by its use the general appearance of the lawn has been much improved. No disfigurement is now caused by horse's hoofs, and the motor machine can be steered and turned very much more easily than the horse machine. Even in situations where the lawn is much broken up by flower beds, or sharp curves, an intelligent man after a few days' practice finds no difficulty in working the motor. It has also to be borne in mind that a man and horse can be otherwise employed. We have used the motor for rolling the turf during the winter months with excellent effect, it being necessary merely to remove the cutters and replace the wooden rollers with metal ones to give a better balance to the machine. It is important to have plenty of engine power to these motors. *W. Fyfe, Lockinge Gardens, Wantage, Berkshire.*

Answers to Correspondents

EDITOR AND PUBLISHER.—Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the EDITOR. The two departments, Publishing and Editorial, are quite distinct, and much unnecessary delay and confusion arise when letters are misdirected.

ARUM LILY: *H. P. L.* See reply to *A. J. K.* in the issue for April 11, p. 240

BOOKS: *W. T.* The à la mode series of works by Mrs. de Salis is published by Messrs. Longmans, Green & Co.; the other book you mention is, we believe, out of print

COCKROACH: *G. A.* The insect is one of the foreign species of cockroach Periplaneta. This creature is now common in many herbaceous and plant stoves in this country. It may be killed by phosphorous paste or any of the other methods that are adopted for destroying the common cockroach.

CONTRIBUTIONS: *J. H.* The Editor will be pleased to consider any articles you may submit for his approval.

CORRECTION: In the address of the Stafford Road and Sunnyrise Market Nurseries Co., Ltd., given on page xii. of our last issue, for Cravenswoth read Cravenhurst.

CURLED KALE: *J. K. K. & Sons.* The leaves you send represent an excellent type of this useful vegetable, but they exhibit no advance on varieties already in commerce

CYCLAMEN: *Z. W.* (Henley-on-Thames). As we do not know the treatment your plants have been given, it is difficult for us to say why they have not flowered satisfactorily, especially as the corms are only two years old. At that stage they should be in their best condition, corms of an older age being liable to rapidly deteriorate, and eventually be capable of producing only flowers of small size and poor quality. Cyclamen plants having just passed from the flowering stage, it is quite natural for them to develop a fair amount of foliage. It may be that your plants have been kept in too hot an atmosphere, or under the shade of other taller growing plants. In any case the best thing for you to do at this stage is to arrange the plants in a cool frame gradually giving them less water at the roots, but not withholding it altogether, as this would cause some of the roots to perish. Ventilate the frame freely during favourable weather. After a period of a few weeks, during which time the plants have rested, they may be turned out of their pots and repotted, giving them a shift into larger pots if the roots are in a healthy condition, but if the soil appears sour and the roots show any evidence of decay, shake off all the old soil and re-pot them into clean pots of the same size as those which contained them previously. When they have been re-potted, return the plants to the frame, where they will need to be provided with shade from direct sunshine. Close the frame moderately early each afternoon. New growth will soon develop, when more air may be given, and as the season advances and the weather becomes warmer, the lights may be removed from the frame entirely, thus exposing the plants to the beneficial effects of night dews. Vaporise the frame at regular intervals to prevent insect pests. At the end of September it will be necessary to remove the plants from the frame and place them on a stage in a light and well-ventilated house, arranging them as near to the glass as possible. At that stage a little manurial stimulant may be applied to the roots, and the heat of the house should be about 55°, with the ventilators open just a little. This may rise to 60° or 65° under the influence of sunshine, but it should fall again to 50° at night. If it is necessary to hurry the plants into bloom, a few degrees extra heat will not harm them, but at all costs the atmosphere must be prevented from becoming excessively moist and confined.

FLOWER CULTURE FOR PROFIT: *Constant Reader.* It is somewhat late to make a start, as many subjects should by now be sown, and as you do not wish to purchase stocks of plants, your only plan is to raise them from seed yourself. You should lose no time in making a sowing of Sweet Peas, which furnish good returns as cut flowers, if you can dispose of them locally. As you have a small greenhouse, you could make a sowing of half-hardy annuals, including Asters, Zinnias, Stocks, Scabious, Centaurea, Gypsophila elegans, Gaillardias, African and French Marigolds, Silene, Verbenas, Saponarias, and the like. This need not deter you from sowing seeds of hardy annuals out-of-doors. Dahlias, of floriferous garden varieties, are useful plants for furnishing flowers for cutting, perennial Sunflowers, Rudbeckias, including R. bicolor, perennial Asters or Michaelmas Daisies, are all useful plants for furnishing flowers suitable for decoration. You must, however, remember that the trade in cut flowers is very keen, and unless you have a good local market for your produce you will not be likely to make the business remunerative. We hope you are not attempting to do so without such necessary aids as available capital and trade experience. With regard to the Tomatos, these should be planted in the warmest quarter of the garden, and, provided the summer is favourable, they should prove remunerative; but you must remember that in most localities a good crop of Tomatos out-of-doors is only obtained once in about three years; it is a very speculative crop in the open. The north border is not suitable for flower cultivation.

GARDENER'S NOTICE: *W. T.* See reply to *J. H.* in the issue for February 29 last, p. 144.

LANDSCAPE GARDENING: *Mark.* The work you mention is much the best on the subject.

LAUREL: *Correspondent.* There is no trace of fungi or insects.

LIME FOR A LAWN: *G. H.* You should not apply caustic but slaked lime to the turf. Spread it evenly over the surface at the rate of about 2 lbs. to the square rod.

LOBELIA PLANTS: *E. W.* There is no disease present in either of the plants you send. The blue colouring in the stem and leaf is a common condition in seedlings of Lobelia cornpicta.

MARKET GARDENING: *F. S.* No licence is needed to engage in the occupation of a market gardener, and no registration is necessary.

NAMES OF PLANTS: *A. M. Davy.* Chrysosplenium oppositifolium. *T. R.* Cassandra calyculata. *D. W. C.* Oleana myrsinodes. *Hortus.* Grevillea rosmarinifolia.—*H. A.* Helleborus viridus.

PEACH SHOOTS DISEASED: *W. E.* The disease affecting your Peach trees is "Silver leaf," for which no cure is known. It is important that all affected portions of the plant be cut off and burned, otherwise the disease will spread to other parts of the plant.

PEACH TREES FAILING TO FRUIT: *H. F.* We suspect the trouble is to be found in the borders, especially as the buds drop in the spring and the soil rarely requires water. If the border is properly drained, the moisture would pass away quickly, and when the trees are actively growing the soil about the roots will become quite dry. You should overhaul the borders next winter. When using paraffin as an insecticide the greatest care is necessary not to apply it in too great a strength.

STOPPAGE OF WAGES: *T. L.* We advise you to consult a solicitor on the matter, but you should first find out if your employer acquiesced in the agent's action.

THE FRENCH GARDEN: *E. K.* We are informed that for a French garden having an area of two acres, with 400 to 600 lights and 2,000 to 2,500 cloches, the necessary supply of water which should be contracted for is 1,000,000 (one million) gallons per annum. The average cost for this quantity is £40 to £60, according to the district. It must be specified in the agreement that the rate is to cover the quantity per annum, for if the contract is quarterly (as it usually is), the price would be excessive for the winter months, and an overcharge would be made for the midsummer quarter. The price of the manure will vary from 2s. 6d. to 7s. per ton, according to the distance whence the supply is obtained. No profit can be made if the cost is more than 9s. per ton. It is advantageous to obtain the manure from a contractor who keeps at least seven or eight horses. When making a contract for that item, it should be ascertained if the horses are well-fed and hard-worked, for these circumstances affect the value of the manure. Long and strawy manure is preferable. For a garden of the size indicated above the labour-bill will work out as follows:—Two well-experienced workmen, £180; two women, £60; one foreman, £100; total, £340. The rent varies considerably; for a house and garden in full working order, including all the materials, sheds, stables, &c., close to a market or a station, it would probably be about £120 per annum. These quotations are given according to the French tariff.

TOMATOS DISEASED: *M. B.* Your Tomato plants are affected with "sleeping disease," caused by Fusarium lycopersici. All diseased plants should be removed and burned, as recovery is impossible. The same soil should not be used for Tomato culture again, and in any case a free application of quicklime should be incorporated with the rooting medium.

VINES: *A. B.* Abortive bunches, such as you send, may be found in almost any vinery; but their presence in large numbers indicates enfeeblement of the plant, due either to malnutrition or age. We suspect that, in your case, it is due to the latter condition. Train in a few young rods to replace some of the older ones, and do this so that they may be taken out alternately. The soil you send appears charged with an excess of organic matter. This should be corrected by a free addition of mortar rubbish, or some other form of lime.

VINES DYING: *J. H.* The vine roots are attacked by eelworms. There is no disease present on the Azalea plant you send; the failure is due to some improper method of treatment.

VIOLETS: *R. F.* The purplish outgrowths from the centre of the flowers are petaloid stamens. This condition is the first stage in the duplication of the petals, resulting ultimately in a double flower. You should send examples of the flowers to some Violet specialist; perhaps Messrs. Cannell & Sons, Swanley, Kent, will be able to tell you if the variety is known in commerce.

WISTARIA FAILING: *J. T. L.* The inflorescence exhibits a condition due to excessive stimulation of growth, not necessarily caused by undue forcing.

THE ALPINE AND OTHER DAPHNES.

THE many species of Daphne introduced to gardens within recent years have not all proved of equal value to the cultivator, and a review of the several species that can with advantage be used in furnishing rock gardens will perhaps be more useful from the point of view of restrictive selection than that of a general recommendation.

Several of the rarest species are likely to remain so, owing to extreme cultural difficulties; others that are described as beautiful or showy need considerable additions to their attractiveness to really make them worth growing. Those species that are good are among our most cherished possessions, and the presence of a few uninteresting species should not be allowed to detract from the merit of others.

Fifty years ago all species of Daphne, save Laureola odora and the Mezereon, would have given trouble to cultivate: they are particularly unhappy when subjected to pot culture, needing more generous rooting conditions than pots can afford.

The steady development of well-planned rock gardens which has become such a feature of modern gardening has provided even for those Daphnes that are generally difficult of management something towards their needs, whilst for those species that are more amenable to cultivation it is now possible to provide ideal conditions in which they can revel and thrive. The Daphne is a model rock shrub. It enjoys the coolness and moisture always present where stone touches earth. It will grow in a fissure, on a mound, or in a depression provided the conditions are always cool. Those species which are not too tender for our climate will live for many years, aided by the annual top dressing of soil that every rock-plant ought to get in spring. Most of the true Alpine species have the root system of Gaultheria—a thick mat of fibrous roots just below the surface; they need a broad area of good surface soil only, but it must not be less than six inches in depth or it will dry out too readily. Although commonly cited as peat-loving shrubs, experience proves a good mellow loam well charged with grit to be excellent rooting material for the strongest species, whilst those of dwarfer stature delight in the addition of leaf-soil and stone chips in quantity to the staple. All Daphnes thrive best in slight shade; they will do without it, however, if the soil is fairly moist, but in dry districts likely to experience drought at midsummer, the provision of shade saves the plants from defoliation and check. Much has been written on the practice of covering the stems of sub-prostrate Daphnes with large stones, thereby inducing them to root afresh. In Alpine surroundings a similar system of rejuvenation is persistently going on with every prostrate plant, and on many areas of broken heather ground in this country a system of rejuvenation closely allied to the preceding teaches a kindred lesson. The species and varieties of Daphne are not numerous, and if one wishes for really attractive plants the good and desirable species are only about six in number. All are deliciously fragrant, and the few species that lack garden value may perhaps be valued for their fragrance alone.

D. alpina is a dwarf sub-prostrate species from the Italian Alps, distinctly shrubby and evergreen, the flowers of which are produced in tiny clusters of white in May and June, and much resemble those of Bouvardia. It is one of the most difficult to manage, preferring to grow in a rocky fissure in nothing but light soil and stone chips, and it will stand the fullest exposure to sunshine if only the fissure is always a little moist. Our winters sear its foliage in open beds.

D. arbuscula is a new-comer, described as closely related to D. petræa, and producing rosy-pink flowers. I have not seen its flowers.

D. Blagayana is a very charming Carniolian species, although it is one that has long proved troublesome to manage, but the general adoption of a system of layering has helped the plant forward by leaps and bounds. It is a prostrate shrub, with a lax habit, each stout branch terminating in a cluster of white or cream-tinted flowers. It delights in shade and leafsoil in plenty, but in the West of England and Scotland, and in Ireland, where moister conditions prevail, it thrives in the fullest sunshine. It is a plant for the lower reaches of the rock garden, where it can ramble at will, and where every matured shoot can be layed by placing a stone upon it, the growing and leafy points being free. This plant proves very intractable under pot-culture, many specimens perishing early when grown thus. It flowers in April and lasts till May and June.

D. Cneorum, the Garland Flower, is in many respects the most attractive of all species, and in the moister climate of the West and of Ireland it forms, in May, lovely mounds of pink that everyone must admire. It grows as a straggling bush of dark green colour, modelled on the lines of Rosemary, but dwarfer and less bright in its foliage. More than half the growths, when healthy and strong, terminate in pretty rose-pink clusters, distinctly Bouvardia-like, and very persistent. The fragrance is most marked, recalling that of most Cruciferæ (i.e., Matthiola, Malcolmia, Cheiranthus), and it is particularly powerful and refreshing in the evening and after rain. I have seen many instances where the use of peat has proved detrimental to this plant. It undoubtedly appreciates lime in limited quantities, and I can recommend mellow loam and leafmould in equal parts as the best soil for it, weighting the whole with a few pieces of soft mountain limestone. Thus treated, and given shade for a year or two, it will thrive. Like most Alpines, it resents neglect, and damage done at midsummer is often not in evidence till the next spring, when the growthless, flowerless tips of all the branches tell their tale of past neglect.

Var. majus I have seen true several times. It is a glorified Cneorum, but a clever cultivator can make all D. Cneorum typically majus, whilst a less clever cultivator can make the true variety majus a worse plant than well-grown Cneorum. I suspect the original var. majus fared better than his fellows.

D. Genkwa.—A rare and tender species that grows well in the west only, such specimens as one sees or can keep alive in the east of England being objects of utter misery and in no respect commendable as garden plants. It is a very gaunt, sketchy-looking shrub, the pale lilac flowers of which, borne in loose clusters, have earned for it the name Japanese Lilac. In Cornwall it is a passable garden plant, with the disadvantage of being quite deciduous. Generally it resembles a forced Persian Lilac whose growth had been arrested or checked by drought. It is very fragrant, but clearly a plant for the enthusiast only.

D. Laurcola, the common Spurge Laurel, is an attractive shrub, but its flowers—citron yellow and in small clusters—are not very showy. One can value the plant for its stout evergreen foliage, and it is particularly useful for filling large spaces in the rock garden in open sunshine (if the soil is moist) or under trees. The bushy habit is in keeping with the boldest rock formation, and the plant is ideal for the planning of belts of mountain scrub in connection with large rockery areas.

Var. Philippii is more dwarf and compact, rarely exceeding 2 feet in height. Its flowers are produced in April and are greenish yellow

in colour, differing but little from those of the type. It is a capital evergreen for the small rock garden, and in the hands of a skilful planter could be well grouped in a typical Alpine scene.

Var. purpurea is a dwarf Laureola whose leafage alone justifies its name.

D. Mezereum (Mezereon). I have many times tried, and am able to recommend, both the white and purple forms of the Mezereon for a novel use in the rock garden. Although they will attain the dimensions of a small tree in the course of 20 years, they are too slow of growth ever to get out of hand, and timely stopping will induce a bushy habit they are not likely to lose. They are rarely used as rock-garden shrubs, yet the rock garden offers ideal conditions for them, for the shelter a winter-flowering tree or shrub invariably needs is to be found there. A large recess in the rock garden filled with Mezereons, the soil at their feet carpeted with the Neapolitan Cyclamen and with Anemone blanda, gives a picture of happy grouping many would admire.

D. odora, the beautiful, tender, evergreen, winter-flowering Daphne from China and Japan, proves hopelessly incapable of happy growth in the east of England, even if given the protection of a south wall. Certain forms collected from colder districts, characterised by a restricted vegetative system, may survive, and one occasionally meets with a few instances of northern Japanese forms establishing themselves. They do not, however, thrive indefinitely and cannot be generally recommended as hardy, even with protection. In the west and in Ireland D. odora is in better condition, and if constantly pegged down it will survive many of the hard winters that are sometimes experienced even in the West Country. There are white and pink-flowered D. odora, and a particularly hardy form called Mazelii with white-margined leaves.

D. oleoides (fioniana hyemalis).—A very pretty evergreen less than 3 feet high, whose small, glossy leaves and rosy or lilac-pink flowers, recall those of a lax cneorum, are sparsely produced in May. It is a native of Crete, and needs a sheltered and warm site. When selecting specimens for planting, it is desirable to choose those grafted low down. This and most other species, not readily increased by layering, are grafted on Laureola, and unless the stock is well buried, and thus rendered partially inert, the scion will never root on its own account, and its life will be shortened.

D. rupestris (petræa) is one of the latest arrivals, and a very fascinating plant it is. It forms a low hillock-like bush of pretty foliage literally studded and fringed with pretty flower clusters that suggest those of a Bouvardia in shape, and are coloured a lovely rose pink. They are produced in quantity in May and June, and can be gently forced, so as to flower earlier. It is essentially an Alpine, and is more amenable to pot culture than any other Daphne. It thrives well under conditions suitable for D. cneorum, and it enjoys a similar position in the rock garden. The largest plants I have seen do not exceed a foot in height and diameter. It is a native of the Tyrol. *G. B. Mallett.*

THE ROSARY.

WORK IN THE ROSE GARDEN IN MAY.

Newly-budded Roses of all kinds will require unremitting attention during May. Standard and half-standards on the Briar should be first looked after, as the tender growths will be exposed to the winds and will need securing to hazel sticks. Following these, buds on the dwarf Briar, Manettii, and De la Grifferie stocks should receive attention. When there is a difficulty in getting the dormant buds on dwarf plants to start into growth, I have found it a good plan to cut half-way through the stem of the plants just above the bud. This checks the flow of the sap at that point, and induces the buds to grow. The Rose beetle is, during May and June, very injurious to standard and half-standard Roses on the Briar; the pest is usually present during the evening and night, when it eats off the young growths. Prompt measures should be taken to destroy this pest. If the shoots of established dwarf and standard plants become too crowded by the end of May, the weakest growths should be cut off. An occasional dressing of dissolved bones applied at the rate of 4 oz. to the square yard, given during their growing season, is very beneficial to all Roses; it should be given during moist weather. Rose cuttings inserted in October, also those of Manetti and Briar stocks planted during the winter, should be given copious waterings during dry weather, and the soil about them be trodden firmly. Any vacancies in beds and borders can now be filled by plants turned out of pots. See that the plants are made secure by staking and tieing. Noisette and Tea Roses planted in borders under glass that have flowered can be pruned back to a few buds at the end of the month. They should be kept rather dry at their roots for some weeks, after which moisture and some good stimulating manure should be given, or the mulching may be renewed.

The autumn and a portion of the spring-grafted plants that have been repotted will, if sufficiently hardened, be ready for placing outside by about the 20th of May. It is a good plan to plunge the pots in beds up to their rim and afterwards to top-dress the plants with half-spent hot-bed manure. Any specimens that require a larger pot should be shifted before being plunged in the ground. Plunging keeps the plants cool during the hot, summer months, saves much watering, and enables the plants to make vigorous growth by the autumn. From

time to time during the growing season, the shoots may be pinched back a little, but straggling growths should be shortened considerably more, in order to induce the plants to make a compact and bushy growth. The early-forced Roses of both the H.P. and Tea-scented classes should be hardened off and placed outside on a bed of ashes. Those of the Tea section will furnish a supply of flowers in the autumn, but they must be kept dry at their roots so as to enjoy a period of rest for six weeks or two months. At the end of that time the surface soil can be taken out 2 inches and each pot be top-dressed with some turfy loam and bone dust. At the same time overhaul the drainage, and after moderate pruning, and waterings as required, the plants can remain outside until they break freely into new growth. When the new shoots appear, transfer the plants to a cool, light house or frame, giving an abundance of ventilation during the daytime, allowing the top ventilators to remain open a little during the night. Hybrid Perpetual Roses in pots should not be disturbed until the autumn, as no further bloom can be expected from them this season. The repotting of Roses on their own roots struck in hot-beds during the early spring, should now be completed, in order to obtain sturdy plants by the end of the season. The earliest plants should be given increased ventilation as the season advances. Fumigate occasionally in order to have the plants free from insect pests previously to taking the glass frames entirely off in the early part of next month. *J. D. C.*

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM × CARMANIA

(O. HARRYANUM × O. LUCASIANUM THOMPSONII.)

IN 1904 this plant bloomed at Walton Grange and was given an Award of Merit at the meeting of the Manchester and North of England Orchid Society held on June 16 of that year, as O. Crawshayanum, Thompson's variety. This plant and five or six more that were raised from seeds derived from the same pod puzzled me for a long time, as they all differed greatly from my plants of O. × Crawshayanum. By chance I asked Mr. Stevens, the gardener at Walton Grange, which variety of O. Halli they were raised from: his reply was O. Halli nigrum. This plant was for a long time at Walton Grange and elsewhere considered to be O. Halli, but on examination of my specimen of it (from Walton Grange) when in bloom, I found it was not O. Halli, but O. Lucasianum, a rare and little-known natural hybrid between O. Halli and O. × cristatellum (the latter a natural hybrid between O. cristatum and O. Kegeljanii.)

Thus the difficulty at once disappeared, and the difference between the Walton Grange so-called "Crawshayanum" and my true one was at once accounted for; the difference being clearly seen when the parentage was revealed. All the plants raised at Walton Grange from this seed-capsule and called Crawshayanum must therefore be renamed by their owners O. × Carmania, the name that Mr. Thompson chose when I pointed the matter out to him and Mr. Stevens.

In addition to the variety here above-named, Mr. Thompson has shown a gigantic form of the so-called Walton Grange variety of O. Crawshayanum at Holland House Show, July 10, 1906, and another which was labelled superbum at Manchester Orchid Show, March 3, 1907, when it received an Award of Merit. Other plants are in the Earl of Tankerville's, Mr. Hanbury's, my own, and other collections, and hence they all become O. × Carmania.

Its parent, the so-called O. Halli nigrum, becomes O. Lucasianum Thompsonii, and plants of it are also in Earl Tankerville's and my own collections.

This note will enable the two errors to be corrected. *de B. Crawshay.*

CULTURAL MEMORANDA.

DISBUDDING PEACH TREES.

THE weather has been so cold this spring that much judgment will be required in the disbudding of these trees on open walls, and, although the superfluous shoots should be removed soon after the fruits are set, the work must be in a great measure regulated by the weather conditions, also upon the progress of the young shoots. The tiny fruits require some sort of protection for some weeks, independently of any artificial covering that may be provided; to remove the shoots a few days too soon, or in a wholesale manner, will result in failure. For this reason, it is best to extend the operation of disbudding over several weeks, in order that the tree may not receive too great a check at one time, as this would probably cause many of the fruits to drop.

In order to maintain a well-furnished and shapely tree, it is necessary to retain a new growth at the base of each fruiting shoot, and for choice it should be one on the upper side of the branch. Occasionally, another shoot may be left midway between this one and the leader, provided there is space for it to be trained in. This will replace the old fruiting shoot after it has furnished its allotted space, for the old fruiting shoot should be cut out after the fruit has been harvested. Should these trees when young make very strong growths, they should be transplanted annually, and this is a much better practice than root-pruning. After they have been lifted, the growths should not be disbudded too severely, but the superfluous shoots should be kept pinched during the growing season. This will tend to check the flow of sap, especially if the leading shoots are trained somewhat obliquely, although one need not hesitate to pinch them, if extra robust, when they have made about 12 inches of new growth. Peach blister, or leaf curl, is likely to be more in evidence when cold winds and a low temperature prevail, hence the advisability of retaining a few extra shoots a little longer than

FIG. 120.—CODIUM (CROTON) "FRED SANDER": AS SHOWN AT THE GHENT INTERNATIONAL EXHIBITION. See p. 258 in the last issue.

is usual, in case the selected ones are affected by this disease. Aphis must be guarded against by the use of tobacco-powder, which should be applied to the foliage directly the insects are detected. *J. Mayne, Bicton Gardens, Devon.*

FORCING TREE PÆONIES.

In the long list of hardy plants there are few subjects that can compare with the Moutan Pæony as regards easy culture, and the manner in which it adapts itself to flowering in pots. I doubt if there is any other plant having flowers of equal beauty that can be had in bloom so early in the year by gentle forcing. Undoubtedly there is a great future before it for forcing purposes, and I see no reason why it cannot be retarded in a manner similar to that which proves successful in the case of many other hardy subjects. Some of our leading nurserymen offer them in pots at reasonable prices already prepared for early flowering, but by many growers their value in this direction is overlooked.

With generous treatment they will live for years, and keep increasing in size. I have had plants in 16-inch pots with 20 magnificent flowers open at one time, and these easily obtained early in February, the flowers being little less in size than those developed in the open; ample foliage appears before the flowers expand, thereby increasing the utility of the plant for decorative purposes.

Plants growing in the open may be lifted and gently forced, October and November being the best months for their transference to pots, and when potted they should be placed in a cool Peach house. Plants, however, treated in this way seldom flower again for two seasons following. A temperature of 55° to 60° is necessary to flower them by the months of February.

Established plants may be brought into flower at the present time with little artificial heat, but a cold frame or cool house should be allotted them after flowering is over. By so doing a check is avoided, and flower-buds are formed early for the succeeding season's display. When the weather is warm, the plants should be placed outside and exposed to full sunshine. *W. H. Clarke, Aston Rowant Gardens.*

PLANTS OF POLYGONUM BALDSCHUANICUM FROM CUTTINGS.

Those who have ordered plants of Polygonum Baldschuanicum of the trade are recommended in No. 19 of the *Gartenwelt* to see that seedling plants are supplied, as plants raised from cuttings are of much slower growth. As this assertion is likely to give rise in the minds of purchasers to the impression that cutting-raised plants are inferior to seedlings, Herr Louis Spath controverts this in last week's (March 14) issue of that journal, instancing as the result of his ten years' experience that the shoots of the cuttings reached in the first year a length of 2 yards; and in the second year they formed luxuriant plants, with abundance of shoots. He believes that with the right kind of cultivation, plants from cuttings fulfil the most exacting requirements.

LAW NOTE.

A SUCCESSFUL RATING APPEAL.

A rating case of considerable interest to nurserymen was tried before the Easter Quarter Sessions for the Hertford Division of the county of Herts. Mr. George Beckwith, of the Hoddesdon Nurseries, appealed against the assessment of his nurseries, which had been increased from £240 (gross) and £180 (rateable) in 1896 to £740 (gross) and £370 (rateable) in 1907.

Mr. James Benjamin Slade, F.S.I., of the firm of Messrs. Protheroe and Morris, Cheapside, valued the glasshouses and the other hereditaments at a total of £4,881 4s., which would give a rateable value of £169 8s. Expert evidence was called by the appellant to prove that the buildings and general condition of the nursery were out of date. Mr. A. Lee Rogers, manager to Messrs. William Duncan, Tucker, and Co., Ltd., South Tottenham, horticultural builders, described the premises as a "freak" nursery, the stoke-holes were quite madness, and the boilers were "crank" boilers. He valued the buildings at £4,399.

Mr. Edmund Rochford, Cheshunt, stated the construction of the glasshouses was as bad as it could possibly be. They were the most inconvenient nurseries he had ever seen. The system of heating was wasteful. Personally, he would not have the glasshouses rent free.

The respondents called experts to prove that the assessment was equitable, the rating surveyor declaring that he first of all assessed these nurseries at £591 gross and £394 rateable, but on appeal to the committee the rateable was reduced to £370 and the gross was raised to £740.

Cross-examined by Mr. Macmorran, witness admitted that his original assessment was £524, but it was afterwards put down to £394.

After a quarter of an hour's deliberation the Court found for the appellant.

The appeal was, therefore, allowed with costs, and the figures of the assessment were reduced to £350 gross and £234 rateable, a slightly higher figure than the original amount.

NOTICES OF BOOKS.

* **"Fungus Diseases of Garden Plants and their Cure": Part I. Vegetables, Shrubs, Annuals, Glasshouse and Hothouse Plants.—For Professional and Amateur Gardeners and Nurserymen.**

The author of this little book obtained first-hand knowledge of the common fungus pests which trouble the gardener by practical experience in a nursery. He became a teacher of botany, and, three years ago, was commissioned by the Director of the Royal Botanic Gardens at Dresden to determine and give advice upon the various plant diseases sent in by correspondents. This book is well up to date in its nomenclature, and in its inclusion of recently-discovered plant-diseases. The Continental literature has been carefully searched; foreign journals, too, as is shown by the references to the *Gardeners' Chronicle*, have also been consulted.

The plan on which the book is arranged is excellent. It opens with a glossary explaining technical mycological words. This is followed by a chapter on the general microscopic structure of fungi. Herein is given the necessary amount of botanical information on such subjects as the structure of the leaf (cuticle, epidermis, stomata, &c.). The author then proceeds to a brief systematic survey of the fungi, in which the chief characteristics of the main groups are given, and also the diagnostic characters of the various genera mentioned in the book. Then come some practical hints for the beginner as to methods of examining microscopic fungi, how to cut and mount sections, how to make "hanging drop" cultures, and to carry out infection experiments, &c. Advice is given as to the price of a good microscope, and where to obtain it.

In the next chapter some sound advice is given—from the practical as well as the scientific standpoint—as to the possibility of controlling diseases by paying attention to plant hygiene in all its aspects. This chapter is one of the most important in the book, for it deals with a part of the subject that is too often completely overlooked both by the professional and the amateur gardener. Attention is directed to points concerning manuring, cultivation, supply of water, ventilation, temperature, light, &c. In an interesting chapter on "the direct control of disease without the use of chemicals," the special apparatus used in some parts of the Continent for removing single examples (scattered here and there in the bed) of diseased Tulip-bulbs, together with the surrounding sclerotium-infected soil, is described and figured.

The preparation of fungicides is then described. A preliminary warning is given against buying the often perfectly useless "sprays" that are put on the market. Directions are supplied for preparing Bordeaux mixture, soda-Bordeaux, and the ammoniacal solution of copper carbonate. Useful notes are given on the subject of soil fungicides.

The remaining part of the book (about 100 pages) is devoted to a detailed account of some 400 fungus diseases which attack those plants commonly grown in the garden, nursery, or greenhouse. These diseases are arranged in the alphabetical order of the plants attacked, and so are easily found. The general external (macroscopic) characters of each disease (such as can be seen with the naked eye or under a lens) are given first, followed by the microscopic characters of the special fungus causing the disease. Then the remedy is given; and here we find the author, by virtue of his practical experience, is able very often to give valuable advice. Thus, in the case of the bacterial disease of Hyacinths caused by Bacillus Hyacinthi septicus, the author points out that the variety "Baron von Tuyall" is more resistant than the variety "Tsar Peter." Similarly with the Heterosporium disease of Narcissi, the author is able to give a list of a number of resistant sorts. He adds that Bordeaux mixture has proved very efficacious against this disease, the sprayed plot giving 31 lbs. of bulbs, while the unsprayed plot produced only 20 lbs.

A criticism on one systematic point must be made. The author refers in two places (pp. 27 and 128) to the powdery mildew (Oidium Euonymi-japonicæ (Arc.) Sacc.), which occurs on the leaves of Euonymus japonicus, as "Microsphaera?" There is no evidence that the mildew in question belongs to this genus; from certain infection experiments which have lately been carried out, it seems probable that it belongs to the genus Erysiphe.

In treating of the Rust of Mints (Puccinia Menthæ Pers.), the author omits to state that the mycelium is perennial in the parts of the plant below ground, so that all infected plants ought to be dug up and burnt at once, special care being taken to remove all the underground parts.

It seems curious to find the Potato and its diseases omitted; we must suppose that they have been reserved for Part II.

The various general remedies to be adopted, arranged under the headings of Indirect Methods, and Direct Methods (a) without, and (b) with, the use of chemicals—are 12 in number, and are given in an Appendix. The method, or methods, applicable to the disease under consideration, are referred to by a number; this ensures a saving of space and avoids that wearisome reiteration of sentences such as "Spray with dilute Bordeaux mixture," which we find in some books on the subject.

The illustrations are good; a special word of praise must be given to the photograph of a bed of Anemones, showing the apothecia of Sclerotinia tuberosa at the places where some of the plants had been killed off in the previous season.

An English translation (at the same price) of Dr. Naumann's book, adapted for English gardeners by the inclusion of certain diseases, would be a welcome addition to the list of really useful books for gardeners in this country. *E. S. Salmon.*

* *Die Pilzkrankheiten gartnerischer Kulturgewächse und ihre Bekämpfung.* By Dr. Arno Naumann, Assistant at the Royal Botanic Gardens at Dresden. With three plates and numerous original illustrations in the text by J. Hartmann. (C. Heinrich, Dresden. 156 pp. Published at 3s.)

NEW HYBRID SAXIFRAGAS.

DURING the past year or two many hybrid Saxifragas have been distributed by Herr F. Sundermann, Lindau, Bavaria. Several are very distinct in habit and free flowering, and promise to be welcome additions to an already numerous and popular family of rock plants. With the exception of three, which emanated from the Court Garden at Sofia, viz., S. Borisii, S. eudoxiana, and S. Kyrillii, and S. ambigua, a natural Pyrenean hybrid, the others were raised by himself. Below is a list of the most distinct, with their parent species.

S. ambigua, D. C. (media × aretioides).—This is a natural hybrid, found in the Pyrenees in three forms, which have each received distinctive names. S. ambigua is nearer to media, with red sepals and petals; S. luteo-purpurea is intermediate in character, with red sepals and yellow petals; while the third, S. Lapeyrousii, has green sepals and yellow petals, and is more nearly allied to aretioides.

S. Bertolonii, Sund. (thessalica × porophylla).—By some authorities these two and S. Fredericii-Augustii are made synonyms, but there are certainly two distinct forms worth keeping up as species for garden purposes. These are the Italian S. porophylla, with its short, broad leaves, and S. Fredericii-Augustii (syn. thessalica), which is found in Greece and Macedonia, with much narrower and longer leaves, and prominent chalk pits along the margins. S. Bertolonii is nearer to the Grecian plant, with rosettes of leaves about 1½ inch in diameter, red stems, and leafy bracts tipped with green, bearing a nodding inflorescence of shortly-stalked red flowers.

S. Borisii, Kell. (marginata × Ferdinandii-Coburgii).—This more closely resembles the latter parent, with larger rosettes of silvery leaves and paler yellow flowers. The stems are 2 to 3 inches high, bracteste, glandular, and bear four or five flowers on each.

S. Burnatii, Sund. (cochlearis × Aizoon).—This is a natural hybrid, found on the Maritime Alps, more nearly approaching cochlearis in rosettes of leaves and inflorescence.

S. Elizabethæ, Sund. (Burseriana × sancta).—This was one of the first of the set to be introduced, having now been in cultivation three or four years. It is a very free-growing plant, making spreading carpets of green foliage. The glandular stems are about 2 inches high, tinged with red, and bear from three to five rich yellow flowers.

S. eudoxiana, Kell. (Ferdinandii-Coburgii × sancta).—In this plant the leaves are intermediate between the two species, with the silvery appearance of the first, and longer and more pointed as in the other. The stems are tinged with red, and bear a head of two or three deep orange-yellow flowers.

S. Kyrillii, Kell. (marginata × Ferdinandii-Coburgii).—This and S. Borisii are the results of the same cross, but the present plant is more like marginata. It has green glandular stems 3 inches high, bearing pale yellow flowers, which are as large as those of S. marginata. In the leaves the chalk pits are also more distinct than in the other hybrid of this cross.

S. Obristii, Sund. (Burseriana × marginata).—This is one of the most robust of the whole set, with the exception of S. Burnatii. It may be compared to an enlarged Burseriana, with the same pointed leaves, stems tinged with red and glandular, bearing three or four white flowers of the substance of marginata. It is certainly one of the best. A few chalk pits are evident on the margins of the leaves.

S. Paulinæ, Sund. (Burseriana minor × Ferdinandii-Coburgii).—Something after the style of S. Elizabethæ, but with more glaucous foliage and smaller rosettes. The stems are 2 inches high, tinged red, with pale yellow flowers ¾ inch in diameter. It is a neat and pretty kind.

S. Petraschii, Sund. (tombeanensis × Rochehana).—This plant (fig. 121) promises to be a great acquisition, as it is of neat habit, and very free flowering. There is not much evidence of Rocheliana, except in the flowers, which are large for the size of the plant. The illustration shows a plant in a thumb pot. It has compact glaucous foliage, red-tinged glandular stems 2 inches high, and three or four pure white flowers in each head.

S. Salomonii, Sund. (Burseriana × Rocheliana).—This has now been in cultivation for some years. It has the appearance of Burseriana, but is easier to grow than that species. The stems are tinged with red, while the flowers are pure white and more of the substance of Rocheliana. *W. I.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

MEALY BUG ON VINES.—None of the correspondents writing on this subject mention the Hydrogas Powders sent out by Messrs. Williamson, Gemmell & Co., 263, Argyle Street, Glasgow. These fumigating powders are easily used, and they kill not only bug, but all other insect pests. I am using them exclusively for fumigating this season. *W. Priest.*

FIG 121.—SAXIFRAGA × PETRASCHII: FLOWERS PURE WHITE.

WEATHER IN NORTH CORNWALL.—This district has received a full share of the recent lapse into wintry weather. Snow commenced to fall at daybreak on Friday, April 24, and it soon came down thick and fast. By seven a.m. 1¼ inches were on the ground, and further falls of snow, interspersed with driving showers of hail, were frequent during the day. At times the storm approached a blizzard in severity. During Friday night 12° of frost were registered, and the melted snow in the rain-gauge was frozen to a thickness of nearly ¼ inch. Snow again fell during the earlier part of Saturday morning, and on Sunday evening it was still lying on the slopes of the Cornish mountains Rough Fox and Brown Willey. It is too soon to record the damage done by this unparalleled weather, but it is extensive. Early Potatos, which in many localities here are largely grown, are ruined. Apricots, Peaches, and Plums had set abundant crops: the ground beneath the trees is now littered with the tiny fallen fruits. Early Pears were in full bloom, and, although the blossoms have not yet fallen, they look deplorable. In the pleasure grounds the Rhododendrons and Camellias are badly injured. The Camellia bushes had previously suffered greatly from the severity of the early part of January, and nearly all had shed quantities of leaves. Curiously enough, last year's leaves are undamaged, but those of the previous years—and, in many cases, they had persisted for several years—have turned brown and fallen, thickly covering the ground below and around. One may well term this "the worst spring on record." *A. C. Bartlett, Pencarrow Gardens.*

"FRENCH CRAB" APPLE.—Is not Mr. Bedford who refers to this Apple as synonymous with Northern Greening on page 245, mistaken? The fruits of French Crab are so flattened, rounded, and so green that no one could confuse them with the conical fruits of Northern Greening. According to Dr. Hogg, the real and original name of the French Crab is "Winter" Greening, a name he asserts to be not only its prior name, but is far more descriptive of its character than is that of French Crab. Like many other Apples, it has been burdened with numerous synonyms. It would be well if Winter Greening were universally adopted, although there are numerous other Greenings—Northern, New Northern, Yorkshire, and Rhode Island. It is these frequent similarities in names which are apt to confuse. Easter Pippin, John Apple, Yorkshire Robin, and Ironstone Pippin are some of the synonyms of Winter Greening. *A. D.*

LILIUM NEPALENSE.—It is strange that so soon after referring to the scarcity of Lilium nepalense in my note on "Rare Indian Lilies," published in the *Gardeners' Chronicle* for February 22, page 115, I should discover a large importation of this Lily. A few days ago, on visiting a nursery, I was shown a quantity of large, well-ripened bulbs of this Lily, which, judging by their appearance, should yield a wealth of blossoms. My experience of bulbs imported in quantity is that a certain amount of variation occurs in the colour of the flowers, both the yellow and the purple portions being in some individuals of a richer hue than in others. The same firm has imported a considerable number of large bulbs of L. sulphureum (L. Wallichianum superbum), which is frequently found associated with L. nepalense. This being the case, it is strange that L. sulphureum should be so much more readily established in this country than the first-named species. The fact that these Lilies are not often sent here in quantity would appear to be due to the fact that they, as a rule, occur in widely-scattered districts in Upper Burmah, hence the expense of collecting is an important item. *W.*

SHORTNESS OF LIFE IN PRUNUS TRILOBA.—It is not an infrequent circumstance for plants of Prunus triloba cultivated in pots for early flowering under glass to die by degrees after successful flowering for several years. The causes for this mishap are remedial; generally, it is due to insufficient ripening of the shoots, and to the use of the wrong sort of Plum stock upon which the species is budded. The best stock is the St. Julien. In order to obtain perfect ripening of the shoots, the stronger ones should be cut back to three or four buds from the base, and the weaker be entirely removed. In consequence of this severe pruning, the resulting growths come away with vigour, and, the small spray being disbudded as fast as it appears, the sap is not diverted into shoots that are of little value for decorative purposes. The selected branches grow strongly, and if the plants are exposed in the full sunshine, afforded proper attention during the summer months, and are not allowed to become very dry at the root during the winter, they will live for many years. Prunus triloba requires exactly the same kind of treatment as pot Peach and other orchard house fruit trees, i.e., pots commensurate with the sizes of the plants, a fair amount of drainage, heavy loam, with plenty of rotten manure, and lastly, firm potting. *F. M.*

FRUIT PROSPECTS IN DEVONSHIRE.—The majority of fruit trees, whether against walls or in the open, give promise of a bountiful show of blossom. Apricots and Peaches have already set a good crop of fruits, but it remains to be seen whether these will be affected adversely by the cold climatic conditions of the past few weeks. Some experienced fruit growers think the fruit crops will be small this year, considering the comparatively sunless summer of last season. Morello and sweet Cherries are laden with blossom now expanding, but I fear the cutting winds from the north will prove disastrous in the case of those trees trained on northern aspects. *J. Mayne, Bicton Gardens, Devon.*

Fruit Prospects in Worcestershire.—On Thursday, April 23, snow fell in different parts of the country, and on Friday morning the thermometer on the screen registered 6° of frost. This was followed on Saturday morning by 4°, and this morning (Monday) by 3° of frost. After careful examination to-day (April 27) of the Plum blossom in the County Experimental Gardens at Droitwich, I find the following varieties injured in the order given:—Most injured.—Blue Rock, Prince of Wales, Bittern, Mallard. Less injured.—*Kirke's Seedling, Curlew, Grand Duke. Still less injured.—Jefferson & *Victoria, *Prince Engelbert, *Diamond, *Swan, Rivers' Early Prolific, *White Perdrigon, *Czar, Monarch, *Coe's Golden Drop. Least injured.—*Reine Claude de Bavay, *Pershore, *Winesour, *Transparent Gage, *Purple Gage, *Early Orleans, and *Sultan. Those marked with an asterisk still have many unopened flower buds, and, therefore, are capable of yielding good crops if the weather proves propitious. The following varieties had not commenced to open their flowers last week, and are at present uninjured.—Belgian Purple, Cambridgeshire Greengage, Belle de Louvain, Denniston's Superb, Early Transparent Gage, Leigel's Apricot, July Greengage, Oullin's Golden Gage, Orleans, Peach, Red Magnum Bonum, White Magnum Bonum, Smith's Purple Prolific, Pond's Seedling, and Washington. All these trees are grown in the open, and have no protection from north-west, north, or north-east winds; the ground on which they are planted slopes sharply to the north *J. Udale.*

The Cultivation of the Clematis.—Mr. John Smith, in his article on "The Cultivation of the Clematis" in the issue for April 4, p. 218, states:—"When the graft has started into growth, the portion of the stem where the stock and scion are joined should not be imbedded in the soil, and when shifting the plants into larger pots this junction should be raised 2 or even 3 inches out of the soil, to fully expose the union of the graft, that it may become hardened, and thus form a woody texture." I do not agree with Mr. Smith's statement that the cause of failures in young plants is due to embedding the scion. When the Clematis is grafted, the scion should be buried, to enable it to form roots, and thereby assist the plant. If a Clematis that has its graft buried be examined, there will be found a profusion of roots on the part above the union, but the stock will be found to have made little progress in this direction. It does not matter about the wood becoming hardened, for if the scion is buried, it becomes adapted to being in the soil, as is seen in the abundance of roots it produces. I graft several thousand Clematis every year, and I do not find that embedding the scion is a failure, but the contrary. *E. C. H. Westley, 7, Lindley Street, York.*

Spring Flowers at Kirkmaiden, N.B.—While Snowdrops and Crocuses were considerably later than usual in flowering this season, Daffodils have—in some instances, at least—put in an appearance before the usual time. The first to open here was Narcissus Scoticus, a very graceful and free-flowering Daffodil, which, when planted on verdant lawns or beneath venerable trees, where there is usually abundant and congenial leaf-mould, creates memorable effects, and is, perhaps, of all the fair flowers of its class, the most valuable for naturalisation in those picturesque situations. I find that such fine Narcissi as Emperor and Empress, Grandis, Maximus, and the imperial Madame de Graaff are also highly successful, and eminently ornamental, when planted in Grass. These are at present in exquisite bloom. But perhaps the most impressive of all Narcissi, when planted in such conspicuous positions and with such a lovely environment of greenery, are N. ornatus and N. poeticum, both of which are very early blooming and strikingly attractive. Here they are invariably interspersed with Tulips, of which the first-flowering forms are charmingly associated with Narcissus ornatus, the latest varieties being contemporaneous with Narcissus poeticus. In my garden at this season of marvellous floral resurrection, the predominating glories are the flowering trees, pre-eminent among which is the Persian Plum, Prunus Pissardii, with its delicate white flowers and dark, chocolate-coloured leaves. Very beautiful, in many instances, are also the virginal shoots from the Rose trees, especially those which adorn Warrior, an artistic advance upon Papa Gontier; W. E. Lippia, a lovely native of Newtownards; and Madame Joseph Combet, of which the variety last mentioned is a semi-climbing and grandly effective Rose. *David R. Williamson, Manse of Kirkmaiden.*

Forcing of Bulbs.—The following is an account of what I venture to think is a new method of forcing bulbs in this country, although it has been practised in America for a number of years. Mr. Robt. Whyte, gardener to Jno. Steward, Esq., Carlton Curlieu Hall, near Leicester, has practised the system with great and uniform success, which has led me to make public his methods. The preparation of the soil I will give in Mr. Whyte's own words—"With regard to the soil used, it is mixed in the following proportions: four barrow loads of good old turf, which has been stacked for at least nine months, and into which has been put between each layer of turves a good sprinkling of soot and fowl manure; one good barrow load of manure from a spent mushroom bed, half barrow load of leaf-mould, and a small quantity of suitable chemical manure. The turf is carefully broken up by the hand, the manure and leaf-mould is put through a sieve having a half-inch mesh, and the whole is very carefully mixed and turned many times before it is used. Care must be taken that the soil is not too wet nor too dry. With this mixture I have never had a failure. I may add, I never use pots of a less size than 6 inches in diameter, and I never plunge the pots." In potting the bulbs, unusually large receptacles are employed, a 6-inch pot being used for a single Hyacinth bulb, and other bulbs are potted in a similar proportion. One large crock only is placed over the hole in the bottom of the pot; the soil is then made very firm, and far more so than is usually the case. The bulbs are inserted with just the "necks" visible above the surface. As soon as they are potted, and without watering, the bulbs are placed on the floor and on shelves, one above the other, in an old, disused cow-shed, from which all light is excluded. Here they remain for at least nine weeks, during which time they are given no water and no attention whatever, excepting that during severe frost the pots are covered with dry hay. I visited Mr. Whyte on March 4th of the present year, and found his bulbs in all stages of forcing; some had finished their flowering, others were in full bloom, and still others were developing their inflorescence in various stages. I was impressed with the very dry condition of those which still remained in the dark shed. The surface soil was so dry and so firm that one had great difficulty in pinching a little off with the thumb and finger, while every pot when tapped rang as hollow as a bell. Yet the soil, when turned out of the pot, was not really dry; and healthy white roots ran right down to the drainage hole. The bulbs are taken out of the shed as required, and put into a cold frame, and are shaded with mats until the leaves become green. Then, and not till then, are they watered with tepid water. The mats are removed, and ventilation is given on all fine days. Here the plants remain until they have made ample foliage. It will at once be seen wherein this system of bulb-forcing differs from the method usually employed in this country. To me the most remarkable thing is the dry condition of the soil. Besides attaining uniformly good results from this system, Mr. Whyte further claims a great power of retarding his flowers, for he says that the bulbs may be kept almost at a stand-still for weeks in the darkened shed so long as water is withheld, and as soon as the leaves have become green and water is given the blooms develop just as well as if they had been brought out earlier. Bulbs are not

Fig. 122.—Cattleya Mendelii, Holford's variety, as shown at the Ghent International Exhibition. (See p. 284.)

the only plants cultivated well at Carlton Hall; one might instance Gloxinias in full bloom early in the new year, Adiantum Ferns with their new fronds fully developed on March 4th, really good Grapes produced on vines which have been grown in pots for eight or nine years, and of many others. *J. Duncan Pearson, The Nurseries, Lowdham, Notts.*

Gunneras.—Frequent references have lately been made by correspondents in relation to the hardiness and moisture-loving nature of these plants. Gunneras, however, can have too much water in winter, and it is by no means an unknown thing for a plant to refuse to grow when planted under the most approved conditions of moisture, &c. Too frequently this condition of root-moisture is regarded as the all-important item, and errors are made in consequence. It is, however, quite true that in certain soils, and especially in those of a light nature, these plants revel in abundant moisture in summer-time and are not injured by wetness at the roots in winter. In soils of a very heavy nature it will be found a good practice to excavate a cart-load of the clay soil and to replace it by some light loam and leaf-mould. In this way an incentive is given to an early and luxuriant growth. It is not every garden, however, that is possessed of a pond, lake, or stream, but it is well to remember that these giant-

Fig. 123.—Cocus nucifera var. aurea, as shown at the Ghent International Exhibition. (See p. 257.)

leaved plants can be well grown away from the water's edge. In the late Mr. Robert Parker's nursery at Tooting, a fine plant of *G. scabra*, with a leaf spread of some 15 feet to 18 feet, was for many years an object of interest and beauty. The example in question was planted in the light soil of the nursery, and below which was gravel and sand. The plant was never watered except by the rains, and the only winter protection given was a covering of loose bracken fronds placed over the crowns. *E. H. Jenkins.*

The Week's Work.

THE ORCHID HOUSES.

By H. G. Alexander, Orchid Grower to Major G. L. Holford, C.V.O., C.I.E., Westonbirt, Gloucestershire.

The Cattleya house is now very interesting, for many of the plants are either in flower or have their flower-buds advanced in the sheath. Amongst the showiest and most beautiful members in flower are Cattleya Mendelii, *C. Mossiæ*, *C. Laurenceana*, *C. Schröderæ*, *C. Skinneri*, *C. Warneri*, *C. Schilleriana*, and the innumerable hybrids derived from the above, such as *L.-C. Canhamensis*, *L.-C. callistoglossa*, *L.-C. Aphrodite*, *L.-C. Latona*, *L.-C. Hyeana*, *L.-C. G. S. Ball*, *L.-C. highburyensis*, *L.-C. Hippolyta*, *B.-C. Digbyano-Warneri*, *B.-C. Digbyano-Mendelii*, *Brasso-Cattleya Digbyano-Schröderæ*, *B.-C. Digbyano-Mossiæ*, *Lælia cinnabarina*, *L. purpurata*, &c. Only strong, healthy plants should be allowed to flower; weak plants of valuable varieties should never be permitted to develop their inflorescences, which should be removed as soon as they appear. Plants permitted to flower should be given sufficient water to assist the proper development of the blooms, and the rooting material should be kept moderately moist until the period of flowering is past. Specimens with their flowers fully developed are best grouped together at the coolest end of the house, as the warmth and moisture needed by the many other inmates now developing their growth often proves detrimental to the expanded flowers.

Cattleya gigas.—This beautiful summer-flowering species is one of the strongest-growing members of the genus, but it is often a shy bloomer. The plants have now developed a few inches of new growth, and a position close up to the roof glass at the warmest part of the Cattleya house, where they will receive an abundance of light and air, should be selected for them. Failure to flower these plants satisfactorily may often be traced to over-watering during their early stages of growth. Until such time that the new growths are well advanced, and the flower-buds are formed in the partially-developed growths, water must be sparingly afforded. After this time, frequent and liberal waterings may be given and continued until the flowering season is passed and the pseudo-bulbs are completely developed. The re-potting of Cattleya gigas is best deferred until after the flowering period.

Potting.—The present time is a busy season for re-potting, as many plants are now showing signs of renewed activity, and will require attention. Such species of the long-bulbed section as Cattleya granulosa, *C. velutina*, *C. bicolor*, *C. Harrisoniæ*, &c., have started into growth, and the autumn and winter-flowering hybrids, after their long rest, are also commencing to grow. Each year these hybrids become more numerous; the following are among the most desirable kinds, viz.:—Cattleya Portia, *C. Mrs. W. J. Whiteley*, *C. Mantinii*, *C. Ariel*, *Lælio-Cattleya Charlesworthii*, *L.-C. Sunray*, *L.-C. Cappii*, *L.-C. Helena*, *L.-C. Andromeda*, *L.-C. Warhamensis*, *L.-C. Ophis*, *L.-C. Epicastii*, *L.-C. Cassiope*, *L.-C. Clive*, *L.-C. Ingramii*, *Brasso-Cattleya Madame Charles Maron*, *B.-C. Mrs J. Leeman*, &c. There should be no delay in top-dressing and re-potting any of these plants that need it, carrying out the work according to the directions given in a former Calendar.

Seedlings.—In gardens where the raising of seedling Cattleyas and Lælio-Cattleyas is carried on there is much re-potting to be done throughout the spring and early summer. These young, vigorous plants are more or less active from the time they complete the first small bulb up to their flowering stage. As nearly all of them produce roots freely, and soon become root-bound, a liberal shift should be afforded them when re-pottting, and especially the stronger-growing kinds. Those that are approaching their flowering stage should be grown in the Cattleya house, but the younger plants will do better if they are kept by themselves in a small house set apart for them in which a warm, moist atmosphere can be maintained. Overhead spraying is of great benefit to these seedlings, and this should be practised both morning and afternoon on fine days, closing the house early in the afternoon to conserve the sun's heat.

PUBLIC PARKS AND GARDENS.

By James Whitton, Superintendent of the Parks and Open Spaces in the City of Glasgow.

Games in parks.—Judging from the numerous inquiries made regarding the regulations affecting the various games permitted in the Glasgow parks, there appears to be a desire on the part of other public authorities to provide greater facilities for outdoor games in open spaces under their control. The facilities that can be afforded for the various games must necessarily be governed by the situation. In limited areas sports such as football and cricket cannot be allowed, but space may be found for tennis and croquet courts and for bowling greens. The general recreation ground must always remain the strongest feature in a public park, especially those situated in a district in which the members of the working class largely reside. The importance of this point is forcibly brought before my notice at the present time. The day is Easter Monday, which is also the spring holiday in this city. As I write I can see a great part of our largest park, extending to about 70 acres, devoted to golf, on which, perhaps, not more than three or four hundred persons are enjoying themselves at the game. On the other side of the park there is a similar area set aside for general recreation, and in this part of the park there are probably more than 10,000 children, with a few grown-up persons amongst them. It is this feeling of freedom which gives the charm to an outing in the country to town-bred children, and when they have sufficient space for their gambols they are easily controlled. This is exemplified in the instance I refer to to-day, for not more than one constable and two park workmen are keeping this large crowd of youngsters in perfect order.

Areas for special games.—No two public parks provide similar regulations for the control of games: the following are adopted in the Glasgow park. The games of golf and bowling are permitted at a charge which barely covers the cost of maintenance. Clubs are not recognised, and persons forming themselves into a club have no special privilege, but must take their chance of playing in turn with the general public. The by-laws permit the parks committee to grant to a club permission to hold a special match, but few applications are made, as the players usually arrange such matters amongst themselves. We have two 18-hole and one 9-hole courses. Bowling is provided for in 17 full-sized greens, that are distributed in six parks: as far as is practicable, the greens are arranged in pairs, but in one park there are three in a group. Bowling is a very popular game in Scotland, and the Glasgow public are agitating for more greens. In most of our parks a space is set aside for football, but no regulation is in force for this game, and the players that first take possession are allowed the ground. This system has now become very unsatisfactory, and the matter is at present under consideration by the parks authorities. Cricket is not a popular game in Glasgow, and possession of the pitches is given to cricketers in a somewhat similar way that the football grounds are given to the footballers. We are, however, experimenting with an enclosure for the game, and so far the result has been satisfactory. Tennis and croquet are not much favoured by the general public in this district, and those persons who play games generally form clubs on private grounds outside the parks.

THE FLOWER GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

Spring bedding.—The present is a favourable time for taking notes with a view to suggesting improvements for another season.

Seeds of Wallflowers should now be sown in shallow drills, transplanting the seedlings as soon as they are large enough in rows 1 foot apart, allowing 6 inches between the plants in the rows. A selection should be made of the choicest plants of Forget-me-nots (Myosotis), with a view to placing them in the reserve garden later, where they may be allowed to seed. If the ground about them is kept moist, the seeds will germinate freely. If this plan is not adopted, seed capsules may be harvested and hung up in some dry shed or other suitable place, and the seeds sown later in beds. The double form of the White Rock Cress (Arabis albida) is a favourite plant for spring bedding, and it is very effective when intermingled with Tulips. Cuttings inserted in gentle heat as soon now as they can be procured will root readily; this plant may also be propagated in the same manner as A. lucida, by division. Alyssum saxatile may also be increased by division. Sever the shoots from the plants with a portion of the old root-stock attached, and place them in rows in a light sandy soil, pressing the latter firmly about them. Sprinkle the plants daily in dry weather until they are well established. By this system of propagation suitable plants will be obtained for planting in the autumn. The Alyssum may also be increased by cuttings rooted in gentle heat and by seeds. Aubrietia deltoidea is a floriferous plants for spring bedding. There are many varieties, of which græca (blue), Hendersonii (dark purple), Ingrami (large rosy-pink), and variegata may be considered the best. Aubrietias should be propagated by divisions or by cuttings, for when they are raised from seeds, the flowers are very rarely true to colour. Auriculas, Double Daisies, Pansies, Polyanthuses, and Lunaria (Honesty) are other useful spring-flowering plants. The purple Honesty makes a fine subject for intermingling with Cornus sanguinea variegata, and is readily propagated from seeds sown in May. A suitable place for these plants during the summer months is a shady quarter in the kitchen garden. Phlox amœna flowers in April and May; the inflorescences are of a deep rosy-pink colour. The plants spread rapidly, and, similar to P. Nelsonii (white) and P. divaricata (lavender), is very free in flowering. After the flowering is passed, the plants can be increased by division, or by cuttings inserted in pots of sandy soil placed in a shady frame.

Sub-tropical plants intended for summer bedding should now be attended to. The strongest and best plants should be potted in 6-inch pots, in which is ample material for drainage; a good rich compost should be used as a rooting medium. The majority of these plants are benefited by overhead syringings of clear water; they must not be allowed to lack moisture at their roots, and manurial assistance should be given occasionally in applications of weak liquid manure. Fire-heat should now be dispensed with as far as possible, and the greenhouse ventilated freely whenever the conditions will admit. Aphis must not be allowed to infest the plants, and fumigations must be given whenever necessary.

Dahlias.—Shift into larger pots the rooted cuttings of these plants before they become pot-bound. Stake and tie the more forward plants, and place them in cold frames, affording protection at night time from the cold, and a free ventilation during the day. When danger from frost has passed, remove the lights entirely during the day time for the purpose of hardening the plants before they are planted in their summer quarters. The old tubers may be divided and planted in the shrubbery, the reserve or the kitchen garden, where they will furnish a supply of cut flowers. Plant the old root-stocks from 2 to 3 inches deep.

Herbaceous borders.—Ply the Dutch hoe freely to encourage growth and keep down weeds. Destroy any slugs that may be found amongst the young plants.

Half-hardy annuals.—Owing to the cold weather, these plants have still to be accommodated in heated structures, which are now needed for other purposes. Temporary structures may have to be provided for them, and, although this work requires a considerable amount of time, it will be better than risking the plants in the open.

Bedding plants.—The hardening of the numerous varieties of summer bedding plants, such as Pelargoniums, Fuchsias, Abutilons, Humea elegans, Calceolarias, &c., must now be considered, for bedding plants that are allowed to remain in warm houses after this date seldom improve thereby. Shade the plants for eight or ten days after their removal from the warmer house.

Ivy on walls.—When the foliage becomes brown and untidy from neglect and dead wood and leaves accumulate in the shoots, forming a harbour for insect pests, there need be no hesitation in cutting off the whole of the foliage, and if this is done now, the plants will soon be furnished again with bright green leaves. Opportunity should be taken, when Ivy is pruned, for cleaning out the rubbish with a stream of water from a hose or garden engine. If the latter is used, a little petroleum should be placed in the water, for this will destroy any red spider that is present; spider is the principal insect pest of ivy.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree, Hertfordshire.

The weather here during the past fortnight has been most unfavourable for the growth of all kitchen garden crops. Severe frost, cold, north-easterly winds, and a heavy fall of snow have prevailed, and the planting out the various crops raised under glass has of necessity been held over. Every effort will now be needed to compensate for this arrear in order to prevent the various kinds of plants from becoming ruined.

Peas cultivated under glass for an early supply should now be well set with pods, and, to assist the latter to swell, the points of the growths should be pinched out and all side growths removed. Well diluted liquid manure should be applied on alternate waterings, and an abundance of ventilation should be given whenever the weather is favourable. Successional batches of Peas in large pots or boxes may now be safely transferred from the houses to the open ground. Select, as far as is possible, a sheltered, sunny position, such as one on a south border, where the pots can be partly plunged, thus enabling the roots to penetrate into the soil of the border, from which they will receive additional nourishment. The plants should be made secure with strong stakes, and, if frost is apparent, afford them some slight protection. Peas cultivated in this manner give excellent returns, provided they are not overcrowded in the pots, at a little cost, and are available some three weeks earlier than when planted out. Such excellent varieties as Duke of Albany, Edwin Beckett, Alderman, and Quite Content are suited to this system of culture.

Continue to plant Peas which have been raised under glass, and to ensure a succession sow seeds of reliable maincrop varieties every 10 days.

Potatos.—Complete the planting of this vegetable with as little delay as possible. Early varieties in cold frames, skeleton pits, or on early borders should be moulded up immediately the growth is 2 or 3 inches high. Guard against frost injuring the tender shoots, for, however slightly the tops may appear to be damaged, the crop is bound to suffer from its effects.

Tomatos.—Plants intended for planting in the open should be grown in a temperature ranging from 50° to 55°, affording them all the light and air possible. The larger the plants are at the time of planting without being spindly, the greater will be the chance of success. Grow those varieties only which set their fruits freely and ripen them quickly. Plants in all stages of growth under glass should have abundant ventilation and a dry atmosphere about them, otherwise disease will appear. Liberally feed plants which are heavily laden with fruits, and remove the latter immediately they show signs of colouring, finishing them off in a warm plant-house or room.

French Beans.—Place three seeds in each 48 pot, and germinate them in a cool house or pit for planting out on a warm border, where shelter can be afforded towards the end of May.

Runner Beans.—I have always found these to succeed much better and with less trouble when the seeds are sown in pots or boxes under glass. By this system they are safe from danger by frost, the ravages of slugs, &c. The seeds should be sown thinly early in May, and the seedlings, after being properly hardened, should be planted out about the end of the same month.

Spinach (New Zealand).—This is a most desirable vegetable, often proving extremely useful during hot, dry summers, as the plants revel in drought and sunshine. A small bed planted on a south border will generally suffice for any medium-sized establishment. The seed is best sown in boxes at this season, and the seedlings planted out, when the weather is sufficiently warm, but it must be borne in mind that the plants are easily injured by frost. Seeds may be sown in the open garden during the first week in May.

FRUITS UNDER GLASS.

By T. COOMBER, Gardener to LORD LLANGATTOCK, The Hendre, Monmouthshire.

The late Muscat house.—All necessary work of stopping and tieing the shoots, thinning out superfluous branches, manuring and watering of the borders, should receive attention before the vines are in flower, for the plants must receive no check during their period of flowering. Muscat Grapes are not the easiest to set, and no pains should be spared to ensure effective fertilisation; this may be assisted by tapping the rods during mid-day and by introducing into the vinery pollen from some free-setting variety. An atmospheric temperature of 70° during night time, with a rise of 5° or 10° when the weather is cloudy, should be maintained, and in order that the air should circulate in the vinery the ventilators should be opened slightly, except during cold, windy weather. All necessary damping of the paths and borders should be carried out on bright sunny days in the early morning and afternoon, so that in the middle of the day the atmosphere may be dry in order that the pollen may be readily distributed. The final thinning of the surplus bunches should be delayed until it is apparent which of them have their berries fertilised, and any thinning of the berries should also be delayed for the same reason. Muscat vines should be more lightly cropped than such varieties as Alicante and Black Hamburgh.

The early Muscat house.—Vines that are well furnished with healthy foliage and whose fruits are freely swelling will be actively growing at their roots, and they will need to be supplied at intervals with copious applications of tepid liquid manure, or be stimulated by a light top-dressing of some suitable quick-acting manure that should be applied before the borders are watered. As the sun's rays become more powerful there will be a danger, particularly in badly constructed houses, of the leaves becoming scalded or burned, but this can be avoided by careful ventilation. In some cases it may be desirable to lightly shade the glass with a thin coating of limewater or some similar wash. Maintain a moist atmosphere in the vinery by frequent damping.

The early Peach house.—As soon as the fruits on early forced trees commence to change colour discontinue syringing the foliage and slightly increase the ventilation, allowing the ventilators to remain open a trifle at night time if the weather permits. This will give a slightly cooler condition in the house that will improve the flavour of the fruits and lengthen their season. The Peaches should be gathered before they are sufficiently ripe to drop, for if they are allowed to become dead ripe while on the trees their flavour will be impaired; they should be gathered at the point of ripening and be placed in a fruit room. When stable manure is employed for mulching, wood lice are often troublesome in attacking the ripe fruit. These pests may be trapped by slices of Beetroot or Mangel hollowed on one side and placed with the hollow side downwards on the borders. The traps should be examined in the morning and the insects destroyed by brushing them into a vessel of boiling water. Ants are sometimes equally destructive. The number of these pests may be lessened by placing in their haunts coarse sponges that have been dipped in sugar syrup

THE HARDY FRUIT GARDEN.

By F. Jordan, Gardener to The Dowager Lady Nunburnholme, Warter Priory, Yorkshire.

Gooseberries and Currants.—Both these fruits are usually trained in bush form, but they may also be grown as standards and cordons, under which systems they are both ornamental and fruitful. For standard plants choose healthy young trees and train the leading shoot to a straight stake, pinching back all the side growths for about a distance of 4 feet up the stem. Sufficient buds should be left to form the head, and beyond this the plants should be stopped. Young bushes should have all their bottom buds removed if these were not destroyed when the cuttings were inserted. Gooseberry bushes should have at least 1 foot of clear stem. The Gooseberry crop promises well, but these fruits are easily damaged by late spring frosts. Almost as soon as the leaves are formed they are often attacked by the Gooseberry and Currant sawfly, which commences to hatch at the end of April and the beginning of May. Prompt measure should be taken to destroy these pests before much damage is done to the bushes. It is a good plan to examine the shoots two or three times a week for the purpose of destroying any caterpillars that may be found, pinching them with the fingers. A dusting of fine lime and soot is often beneficial to the trees, as it destroys many insects on the plants and in the ground, but an application of Paris Green or some other poisonous insecticide is more efficacious, although there is a danger of some getting on to the fruits, and these poisons should not be used, except in extreme cases, and then the fruits should always be washed before they are sent to the kitchen. Green and black aphis often infest the young shoots of Currant bushes. These may be destroyed by syringing with quassia extract or with one of the many insecticides on the market. Next morning the bushes should be washed with clear water from the garden engine.

Wall trees.—None of the protective material must be removed from fruiting trees on walls unless the weather becomes warmer and more seasonable, and in the case of Peaches and Nectarines, great care must be exercised to see that they are not injured by frost. When the protective materials are removed examine the trees for insect pests; they will probably be found where branches of Spruce or similar evergreens have been used. The trees must not suffer from lack of moisture at their roots. In borders that are in a good condition, and where the roots are near to the surface, it will be almost impossible to overwater the trees in a moderately dry season.

PLANTS UNDER GLASS.

By Thomas Lunt, Gardener to A. Stirling, Esq., Keir, Perthshire, N.B.

Violets.—Plants intended for autumn and winter-flowering under glass should now be planted out in land that has been well manured and has received a liberal dressing of leaf-soil and wood ashes. These materials should be lightly forked in before the Violets are planted. Select plants with a single crown of last season's growth, and place them at a distance of 18 inches apart each way. Spread the roots well out, and should the ground be dry, afford a good soaking of water at the roots directly they are planted. Syringe the foliage every evening with a very weak solution of manure water, for this will assist in keeping down attacks of red spider. Damping overhead or syringing should be practised all through the growing season, and in hot, dry weather a syringing in the early morning will prove beneficial, placing enough liquid manure in the water to just colour the latter. Stir the soil frequently with a hoe, and never allow the roots to become dry, but rather keep the plants on the damp side during their season of active growth. By the time August arrives they should be well established and have developed many strong crowns. Six of the strongest of these should be retained to each plant, and the remaining runners removed. Lightly fork up the soil beneath the layers that are allowed to remain, and press the stems into the ground, placing a stone on them to keep them in position. Roots will soon form; the use of stones is much better than pegs, as the former will keep the soil about the crowns damp. Young established crowns should now be well rooted and ready for transplanting into an unheated frame. All the side shoots and runners should be cut off directly they appear, in order to allow the plants to receive the full benefit of air and sunshine that they may become thoroughly ripened.

Violets in frames.—A good supply of Violets may be had during the winter season by the use of an unheated frame. This should be placed in a south aspect, where the plants will receive a maximum amount of sunshine in winter. The soil should slope from the back to the front of the frame, and be within 6 inches of the glass; it should consist of three parts good loam, one part leaf-soil, and one part wood ashes and sand. When placing the plants in the frame, lift them carefully with the runners attached, but some of these rooted crowns are almost sure to become detached. Any that are broken off may be used for filling vacant places in the frame, as they will produce flowers. Upon no account allow the parent crown to become smothered with useless side shoots, as these will give no flowers, and will be the cause of damping in the plants. After they are planted in the frame, afford one good soaking of tepid water, which will be all the moisture they will require during the whole of the winter. After planting, shade the glass and keep the frame closed for a couple of days, but when they are established in their new quarters, afford ventilation freely on all favourable occasions. Guard against damping in the plants, and remove any injured leaves or flowers that have become damaged in the process of transplanting. Protect the plants from frost all through the winter.

Fig. 124.—Sophronites grandiflora, as exhibited in Major Holford's collection of orchids at the Ghent International Exhibition. (See p. 284.)

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.*

Appointments for May.

FRIDAY, MAY 1—
Franco-British Exhibition (Shepherd's Bush) opens this month.

SATURDAY, MAY 2—
Soc. Franç. d'Hort. de Londres meet. German Gard. Soc. meet.

TUESDAY, MAY 5—Nat. Amateur Gard. Assoc. meet.

WEDNESDAY, MAY 6—
Croydon and District Spring Fl. Sh.

THURSDAY, MAY 7—Linnean Soc. meet.

MONDAY, MAY 11—
United Hort. Ben. and Prov. Soc. Com. meet.

TUESDAY, MAY 12—
Roy. Hort. Soc. Coms. meet. Roy. Gardeners' Orphan Fund Coming-of-Age Festival at the Hotel Cecil, Strand. Nat. Rose Soc. Com. meet. Brit. Gard. Assoc. Ex. Council meet.

SATURDAY, MAY 16—German Gard. Soc. meet.

TUESDAY, MAY 19—
Devon County Agric. Sh. at Plymouth (3 days).

WEDNESDAY, MAY 20—
Roy. Bot. Soc. Exh. at Regent's Park.

MONDAY, MAY 25—
Ann. meet. and dinner of the Kew Guild at the Holborn Restaurant. Anniversary meet. of the Linnean Soc.

TUESDAY, MAY 26—
Roy. Hort. Soc. Sh. in the Temple Gardens, Thames Embankment (3 days).

WEDNESDAY, MAY 27—
Ann. meet. Brit. Gard. Assoc. in Essex Hall, Strand, 7 p.m. Bath and West and Southern Counties Soc. Sh. at Dorchester (5 days).

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—50.5°.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, April 29* (6 P.M.): Max. 63°; Min. 47°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, April 30* (10 A.M.): Bar. 30·1; Temp. 55°; Weather—Raining.
PROVINCES.—*Wednesday, April 29* (6 P.M.): Max. 58° London; Min 43° Scotland N.E.

SALES FOR THE ENSUING WEEK.

WEDNESDAY—
Herbaceous Plants, Liliums, Begonias, Gladiolus, &c., at 12; Palms and Plants, Coniferæ, Ferns, &c., at 3.30, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

THURSDAY—
Unreserved Sale of a choice selection of Plants from the "Bank House" collection of Orchids, by order of S. Briggs-Bury, Esq., by Protheroe & Morris, at 67 & 68, Cheapside, E.C., at 1.

FRIDAY—
A selection of valuable Plants from the "Coundon Hall" collection of Orchids, by order of G. Singer, Esq., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 1.

The Ghent Exhibition.

Our readers are already aware that the usual Quinquennial Exhibition of the "Société Royale d'Agriculture et de Botanique de Gand" is this year invested with even more than its usual interest by reason of its concurring with the celebration of the centenary of the Society's existence.

History seems to have a fascination for most people, and directly an institution or association achieves success of a noteworthy character, a special interest is shown in the circumstances which attended its birth. The history of the Ghent Horticultural and Botanical Society affords a striking instance of a great society with a world-wide reputation which has gradually developed from a most humble origin. The tale was told in an interesting manner in the article by M. Couterick which appeared in our issue for April 11 last. At the commencement of the nineteenth century an inn or publichouse (see fig. 125) in a suburb of Ghent was tenanted by a gardener, and it therefore became a favourite resort for the more enthusiastic cultivators of plants. They met there for the purpose of discussing subjects in which they were mutually interested, and doubtless the inn "Frascati," so far as the conditions of such a house would allow, served to fulfil the same functions as those which are now more perfectly provided for by the debating societies which exist in most civilised countries. Gradually the members would fall into the habit of carrying their more interesting plants and specimens to their favourite resort for comparison and criticism, thus establishing a series of informal exhibitions. But in February, 1809, after hearing from Franz van Cassel, gardener and botanist, a narration of the wonders in cultivation and the new plants he had seen during a recent visit to England, it was resolved to establish a society for the purpose of holding flower shows and promoting the culture of plants in Ghent.

But we need not pursue these details further; the circumstances which attended the carrying out of this resolution, and the continual growth of the newly-established society which afterwards took place, have been already explained. For very many years past, the Ghent Society has held quinquennial exhibitions that have attracted horticulturists from every part of the world, and the more recent shows have been attended with such success that, as was mentioned by the President, M. Callier, at the luncheon after the conclusion of the judging of the exhibits on Friday, it seemed difficult to see in which direction further progress might reasonably be looked for. It was this circumstance which led the late Count Kerchove de Denterghem to devote the greater part of his address to the jury of five years ago, to advocating the need that existed for giving increased attention to the scientific aspects of gardening. It was in this direction that the late President considered further progress could still be made, and his words may usefully be remembered at the present time, when the Society may be said to be entering upon a new era of its existence. In the immediate past this question has claimed much attention. By laboratory research and garden experiments botanists and horticulturists are endeavouring to know more of the plants they cultivate, and to understand the circumstances which attend their reproduction, variation and development. At the present meeting an important item was the botanical lecture delivered by M. Noel Bernard on the subject of the symbiosis alleged to exist between certain fungi and Orchids. He showed lantern slides and specimens to illustrate the lecture, and stated that he has proved it to be impossible for Orchid seeds to germinate unless certain parasitic fungi are present. The Society will do well to give proper attention to matters such as this, even if they may appear to have but little practical value at the moment, for they are fraught with possibilities of great importance to cultivators. At the same time the exhibitions that have done so much to popularise and develop Belgian horticulture will of course continue to be maintained at their present high level of excellence.

Turning to the present show, it is impossible for us to record all the details of such a vast exhibition. In the report which appears upon another page, the prominent features are remarked upon, and details are given so far as space will permit. The exhibit that excited most interest was probably that from M. Charles Vuylsteke, of Loochristy, whose success in the raising of hybrid Orchids has been from time to time recorded in these columns. For some years past M. Vuylsteke has devoted most of his attention to the raising of "blotched" Odontoglossums, but, notwithstanding the flowers he had previously exhibited, no one was prepared for such a display of these most valuable plants as is staged at this show. The centenary exhibition will live in the memory of those who are attending it on account of the first appearance, in such numbers, of this type of Odontoglossum.

Major Holford's exhibits of Orchids and Hippeastrums form another very prominent feature of the show. The Orchids are beyond praise, and the Hippeastrums afford further evidence of the excellence of the strain now in cultivation in Major Holford's remarkable collection. Writing of English exhibits reminds us of the beautiful Hippeastrums staged by Messrs. R. P. Ker and Sons, which have obtained the highest prizes for these plants in the competitive classes.

Of the show generally, it may be said that it is certainly as good as previous ones. The Palms, Codiæums, Cordylines, and other stove plants, also the Acacias, Azaleas, and greenhouse plants so commonly cultivated in the Ghent district are to be seen in the most perfect specimens. It is a grand exhibition, and it is displayed to the public view in a most attractive manner.

The great hall of the Casino, laid out by Mr. Charles Pynaert, very effectively contains, as usual, the stove plants, and in the galleries upstairs, including the Rotunda, are the Orchids, new plants, botanical exhibits, and batches of miscellaneous flowering and foliage plants.

The large temporary building is not placed, as heretofore, in a position adjoining the Casino, but is separated from it by the interposition of an open-air garden planted with Conifers and other hardy shrubs and trees. Owing to this alteration it is not possible to view the Azaleas from the flight of steps which formerly connected the main building with the annexe, but although this is the case, it would be difficult indeed to imagine anything more beautiful than the view obtainable upon entering the large building. Its interior design, as well as the arrangement of the exhibits, were entrusted to Mr. Fred. Burvenich, Senr., and he is to be greatly congratulated on the success that has attended his efforts. The eye would be merely dazzled by the gorgeous display of Azalea blossoms were it not for the skill displayed in their arrangement. The view extends over the beds of these plants, formed on sloping, uneven surfaces, to the further portion, where there are great banks of hardy Rhododendron and huge specimen-plants of Acacias and other hard-wood species. At the extreme end of this space there is a painted background representing a portion of the grounds that

formerly surrounded the "Coupure," thus leaving the perspective uninterrupted.

At one of the sides, a feature is made of a model of the old Inn, "Frascati," and in this building specimens of the species of plants staged at the first show the Society ever held are displayed as nearly as possible in the manner in which they were then exhibited. It is a pretty feature, and has been carried out in a very satisfactory manner. On the other side of the building a good effect has been produced by paintings of South African scenery, which are used as a background for exhibits of species of plants introduced from the Cape.

The jury consisted of 240 persons, of whom 188 are not resident in Belgium, and include 32 from Britain. A distinguished Englishman in the person of Lord Redesdale was appointed Honorary President of the Jury, Mons. A. Viger, a former Minister of Agriculture in France and President of the Société Nationale d'Horticulture de France, acting as the General President of the Jury.

FIG. 125.—THE GHENT EXHIBITION: EXTERIOR OF MODEL OF OLD INN IN WHICH THE FIRST EXHIBITION WAS HELD IN 1809.

In addition to discharging the more serious business connected with the exhibition, the jury were entertained at various "functions" in the most cordial and hospitable manner. Sunday last was a particularly busy day. In the morning the official unveiling of the monument erected to the memory of the late President took place in the Place du Comte de Flandre (see fig. 126). At noon there was an official reception by the Chambre Syndicale des Horticulteurs Belges, and in the evening the Grand Banquet took place in the halls of the Grand Théâtre, at which the President, M. Callier, presided.

BRITISH GARDENERS' ASSOCIATION. A meeting of the London branch of this society will be held at Carr's Restaurant, Strand, on May 14. A paper on "Public Gardens and their Construction" will be read at 8 p.m. by Mr. T. WINTER, Superintendent of Marylebone Parks. The meeting will be open to all gardeners.

DENDROBIUM EPIDENDROPSIS.—Prof KRANZLIN describes in the current number of *Orchis* a new Dendrobium from the Philippine Islands, which has flowered at Erlangen. It is stated to resemble the type of Epidendrum exemplified in E. umbellatum. Unfortunately, although interesting in other ways, the flowers are not attractive, being of a greenish-yellow, and are covered with a sticky exudation.

LILIES OF JAPAN.—We have received from THE YOKOHAMA NURSERY CO., LTD., a brochure containing 40 finely-coloured plates of Lilies, many of which are endemic in Japan. Besides their value from the point of view of a catalogue, the plates possess the additional one of serving as a useful pictorial reference book to some of the finest Lilies in cultivation.

A NURSERYMAN'S VISIT TO MOROCCO.—Mr. JOSEPH CHEAL, a member of the firm of Messrs. JOSEPH CHEAL & SONS, Lowfield Nurseries, Crawley, submitted to the Fruit and Vegetable Committee at a recent meeting of the Royal Horticultural Society examples of exotic fruits which he had brought from Madeira. Mr CHEAL has described this as a most beautiful island. Most of the houses are picturesque in appearance, and about them are planted Palms, Tree Ferns, Poinsettias, whilst verandahs and pergolas are covered with brilliant flowering climbers, such as Bougainvilleas, Allamandas, Passifloras (Passion Flowers), scarlet-flowered Taxonias, Roses, Wistarias, &c. Masses of Ivy-leaved Pelargoniums, with flowers of many colours, ramble over the rocks. Vines are trained to pergolas and other supports, whilst beneath are many kinds of gourds. Describing the gardens near Casa Blanca, he states that Dates, Figs, Pomegranates, and Almonds grow in profusion with a few Orange trees. At Teneriffe he saw the plantations of Potatos, Tomatos, and Bananas that are sent in great abundance to our markets. The valleys at Teneriffe are exceedingly fertile and well cultivated, and the area under culture is increased by terraces that are formed up the hillsides. At Grand Canary he visited Las Palmas, the chief industry of which is the culture of Bananas. The soil of this island is of volcanic origin, and it is carefully prepared by levelling it into terraces, and separating from the volcanic earth the larger stones which are used in forming the terrace walls. Watercourses are constructed through each plantation, large reservoirs being built on the hillsides for storing the water, which flows down cement courses to the gardens below.

NATIONAL FLOWER SHOW AT CHICAGO.—We have received the preliminary schedule of the National Flower Show to be held in Chicago, November 6-15, 1908, inclusive, under the auspices of the Society of American Florists, in co-operation with other American horticultural associations. Carnations, Roses, and Chrysanthemums are represented by their special societies. The schedule provides for 97 classes devoted to Chrysanthemums, 52 for Roses, 80 for Carnations, and others for Orchids, Palms, Ferns, and other foliage and decorative plants, cut flowers, floral devices, &c.

COMMERCIAL FERTILISERS.—The *Complete Report on Commercial Fertilisers*, issued as a free bulletin from the West Virginia University, is interesting as showing the intelligent interest which the American cultivator takes in the value he can get out of the numerous manures that are on sale in his State. The bulletin details a large number of these fertilisers, giving the name of the brand and of the company supplying it. The analysis, as conveyed in the company's guarantee, is printed, together with that actually found in the university testing laboratory. The frank notes that are appended ought to save any man who knows his business from incurring risk of loss, unless he chooses to accept it with his eyes open. A sample remark may be quoted. After giving the results for a particular fertiliser, it is added, "Phosphoric acid low, chlorine excessive, source of nitrogen equal to ground leather." In other cases the remarks are favourable, e.g., "Source of potash better than guaranteed." The bulletin contains much good advice on the use of "artificials" generally, and deprecates as a general rule the use of low-grade fertilisers. Similar analyses on a larger scale are given in *Bulletin* No. 294 of the New York Agricultural Experiment Station, at Geneva, N.Y. The results of the analyses are not always quite the same, but, of course, allowance must be made for varied degrees of completeness in the mixing of the ingredients.

"PHILIPPINE AGRICULTURAL REVIEW."—We have received the first number of the above journal, which is to appear as a monthly periodical, replacing the Press Bulletins which were previously issued at irregular intervals. The *Review* is illustrated by 14 half-tone plates, which would be improved if they bore an explanatory legend, instead of a number, which necessitates reference to the list of contents and illustrations. Another feature which might well be introduced, and too often is wanting from journals of this kind, is the addition of the scientific name to the vernacular one for the plants that are specially cultivated. It is otherwise often difficult to be sure of the species which is meant by authors. The advantages of publications such as the *Review* are too widely recognised to call for comment, and it suffices to say that the first number amply justifies its appearance, and indicates the large number of special agricultural problems which form the subjects of continuous investigation in the islands.

SOCIÉTÉ ROYALE D'AGRICULTURE ET DE BOTANIQUE DE GAND.

Quinquennial and Centenary Exhibition at Ghent.

April 25—May 3.—The proceedings of the Centenary Exhibition may be said to have commenced on Friday, April 24. The members of the jury assembled at about 8.30 a.m., and were photographed in a group at the invitation of the *Tribune Horticole*. At nine o'clock the members listened to a short address from the new President of the Society, M. Alexis Callier, the Attorney-General, and immediately afterwards proceeded to their duties of adjudications. M. Callier said that the late Count Kerchove de Denterghem had already commenced to think out the arrangements for the centenary exhibition. Many of the jurors revisited Ghent as old friends, some of them having been coming even for 50 years past. The quinquennial exhibitions had a stimulating influence upon horticulture as being the means of bringing together representatives of the peoples of different countries. The Society, although celebrating its centenary, had not even one wrinkle. It was the cherished baby of the public, and it had flourished, though in a varying degree, during its whole existence of 100 years.

The Jury was constituted as follows:—*Honorary President:* Lord Redesdale. *President:* M. A. Viger. *Vice-Presidents:* MM. A. Truffant, Noel Bernard, Baron de Grancy, Ruys de Beerenbroeck, Major Holford, Harry J. Veitch, Max Kolb, Dr. Wittmack, Chevalier Radaelli, Enrico Rovelli, F. Lambeau, and Jules Cartuyvels. *General Secretaries:* MM. Philippe de Vilmorin, Abel Chatenay, Victor Lemoine, Dr. Janse, Siebert, R. Seidel, R. W. Ker, and H. Correvon. The jury was divided into 32 groups, and the work of adjudication was accomplished in less than two hours.

New Plants.

It becomes more and more difficult as each quinquennial exhibition comes round, to obtain new plants which have been but recently introduced to Europe. Nowadays the new plants are chiefly the result of hybridisation rather than newly-introduced species. On the present occasion there are new Orchids, Azaleas, and other kinds provided for in their proper sections, and the following notes are therefore upon those plants which were exhibited in the first group of classes which were set aside exclusively for novelties without any specification as to species.

The premier class was for 12 newly-introduced plants that are not yet in commerce. Messrs. F. Sander & Sons, St. Albans and Bruges (Belgium), as on several previous occasions, have been awarded the first prize, which consisted of a Gold Medal. The species exhibited by this firm were described in our last issue, with the exception of Ficus australis variegata, which is shown as a dwarf little plant with oval-shaped leaves very freely variegated with white. The others included Ptychoraphis Siebertiana, Codiæum "Fred Sander," Pinanga Micholitzii, Pereskia Godseffiana, Bromelia tricolor, Encephalartos Woodii, Anthurium Sanderi, Philodendron Ilsemanii, Caladium Centenaire, and Nephrodium gracillimum. M. Maurice L. de Vilmorin, Quai d'Orsay, Paris, also exhibited in this class.

In the following class, M. Philippe de Vilmorin has been awarded a Silver-Gilt Medal for a collection of six new plants not yet in commerce. The species are as follow:—Clematis species (unnamed), Corylus thibetica Potentilla sp., Rhododendron chartophyllum, Sorbaria assurgens (hort. Vilmorin), and an unnamed species of Trollius. Most of these plants are not sufficiently developed for an opinion to be formed as to their qualities, and even the Rhododendron has not yet its flower-buds expanded, but its habit appears exceedingly good, and the plant may be valuable.

The best exhibit in a class for a hot-house flowering plant not yet in commerce is a group of hybrids from Gloxinia and Sinningia. The flowers are very little modified from those of Gloxinia, but the foliage shows a reddish tinge acquired from Sinningia. In some of the varieties which have red flowers it is considered an advantage to get something of the same tint in the leaves, many shades in the same tone or colour being much appreciated on the Continent. In Class 4, which demanded a greenhouse flowering plant that had not been exhibited before the Society previously, M. J. C. Schmidt, Erfurt, Germany, has been awarded a bronze medal for a group of very fine Cyclamens of a strain named "Rokoko," which reminds us strongly of the strain exhibited some years ago by M. de Laange, Brussels, though the flowers on the present occasion show considerable improvement in the colours. The blooms are so modified in form that they are almost flat, and the petals are much fringed.

In a class for a new stove plant, with ornamental foliage, a Medal has been awarded to MM. Jacob Makoy et Cie., Liège, for a very fine plant of Maranta Closonii from Brazil, having cream-coloured leaves marked prominently with olive green. In the same class M. Delaruye-Cardon, Ledeburg, has obtained a prize for a species of Anthurium.

Fig. 126.—The Ghent Exhibition. Memorial to the late Comte O. de Kerchove de Denterghem unveiled during the exhibition.

The first prize for 12 new plants obtained from seed is awarded to M. Anatole Cordonnier Bailleul, for a collection of new Codiæums (Crotons), all of which have broad leaves. The most effectively coloured variety is one named Madame Ernest Delaruye.

A pretty, large-flowered Myosotis named M. Liebestern has obtained the second prize for M. Fischer, Stuttgart, in a class for a new hardy flowering plant obtained from seed.

M. L. de Smet-Duvivier, 281, Chaussée d'Anvers, Mont St. Amand, exhibits in several of the classes in this group. In one case he has shown a variegated variety of Ardisia crenulata, and in another Phormium atropurpureum var. nana. In a class for the most meritorious flowering or non-flowering plants put into commerce since 1903, he has included those following:—Kentia Belmoreana versicolor, Davallia Lansonniana, Anthurium Rex, Maranta insignis, Heliconia imperialis, Acanthus montanus, a hybrid Anthurium, being a cross from A. Veitchii and A. Andreanum album, Dracæna Kerchovei, Sanseviera Laurentii, Buddleia asiatica, &c.

The Orchids.

That the show of Orchids in its best exhibits is infinitely superior to any yet staged at Ghent is the conclusion of all who were qualified to pass an opinion.

Undoubtedly the most remarkable of the exhibits are two groups not for competition, that from M. Chas. Vuylsteke being a most marvellous selection of new hybrid Odontoglossums, the individual merits and beauties of the plants utterly baffling attempts at description, and for which an Œuvre d'Art was awarded with congratulations.

The beautiful and finely-flowered specimens, all of M. Vuylsteke's raising, are arranged in a commodious, ornamental glass case, backed by mirrors and draped in green. About 115 splendidly-flowered specimens, all dissimilar, but many of them of such surpassing beauty as to render it difficult to decide which is the best, are arranged in the case. M. Vuylsteke has accomplished wonders in his crosses of these beautiful Odontoglossums, and violet, claret, ruby, and orange tints are produced in a manner that even the raiser himself did not expect. The first fine break with the new set was made from his beautiful varieties of O. ardentissimum, and with the introduction of the spotted O. crispums it has been followed by inter-crossing with the best varieties of all available species, and the present result, though, as the raiser believes, by no means the final achievement, appears in his magnificent exhibit at the Ghent quinquennial show. If words fail to describe the collection, they are still more inadequate to convey an idea of the beauty and the brilliance of the individual plants. One new hybrid, O. maculatissimum (maculatum × ardentissimum) is unique, and a superb novelty. Its fine spike bears nine large flowers of very distinct characters, the sepals of a bronzy claret hue, the petals heavily blotched with the same colour on the inner halves, and cream-white on the outer, the broad lip whitish, with a large, bronzy red blotch and some pink veining. The varieties of O. Gandavense, with their distinct violet tints, some of which were shown at the Temple Show last year, are more charming than ever, O. Gandavense cœruleum being of a delightful combination of blue and white, and O. G. azureum having the inner parts of the segments violet colour. O. egregium, var. Mad. Jules Ilye de Crom is almost entirely of a delightful tint of bronzy claret with white margins and tips to the segments; O. præclarum, a most beautifully-marked flower; O. Lawrenceanum imperiale, a grand yellow bloom, exquisitely marked with dark purple; O. Wiganianum Phlegon, a densely-spotted and wonderful flower; O. eminens, creamy-white, with clear, purple spotting, and innumerable others, each worthy of the highest praise. Still, among the great show of beauties the later forms of O. ardentissimum hold their own, the blooms being perfect in form and very bright in colour. The richly-coloured forms of O. Vuylstekeæ, the home-raised blotched O. crispum, O. crispum Memoria Battle of Waterloo, and varieties of O. excellens were magnificent.

Notwithstanding the splendid show made at the Casino, M. Vuylsteke is in the enviable position of having a much larger number of nearly equally beautiful Odontoglossums in bloom at his place at Loochristi, and what is to come from the tens of thousands of yet unbloomed plants can only be imagined.

The other grand exhibit not for competition, and for which the finest Œuvre d'Art was awarded, is the superb and artistically-arranged group staged at the end of the gallery by Major G. L. Holford, C.I.E., C.V.O., Westonbirt, Tetbury (gr. Mr. H. G. Alexander), who deserves the thanks of the horticulturists of Great Britain for so well representing them at this exhibition. The group occupies over 300 square

feet, and is most artistically staged by Mr. Alexander, the centre being under the oval niche of the end of the gallery, and the front curved. A tall tree Fern is in the back, with magnificent plants of Odontoglossums, Dendrobium Wardianums, and coloured hybrid Odontoglossums, fronted by an enormous plant of Cymbidium eburneo-Lowianum, many fine Cattleya Lawrenceana, &c. The following enumeration of some of the leading plants in this group will serve to convey some idea of the beauty and variety contained in it. Among the larger plants are Cymbidium eburneo-Lowianum, with 24 spikes, bearing together 124 flowers; a grand specimen of the reverse cross C. Lowio-eburneum, and fine examples of C. eburneum, C. Low-grinum, C. Lowianum, Pitt's variety, C. Lowio-grandiflorum, C. eburneo-Lowianum concolor, and C. Lowianum concolor. The Odontoglossums are represented by a grand selection of fine varieties of O. crispum, of which there are about 100 spikes. One plant has a spike of 52 flowers, and another specimen bears 86 blooms. O. crispum Queen Victoria bears a fine spike; O. c. Mrs. Lindsay, and O. c. Egret, grand white forms; and O. c. Columbine, a pretty spotted variety. Among the others, O. ardentissimum, Westonbirt variety, a real gem of exceptional beauty, bears a spike of 12 purple-blotched flowers; and O. Hallii, O. Andersonianum, the fine O. Wilckeanum, Rex, and O. W. imperiale; O. Pescatorei, with the fine O. P., Westonbirt variety, having a spike of over 50 flowers; O. crispo-Harryanum, O. loochristiense Lord Howick, a very bright flower; O. elegans, good O. triumphans, O. cirrhosum, O. Edwardii, O. Adrianæ Lady Wantage, a charmingly spotted flower; and many other fine Odontoglossums. The Brasso-Cattleyas and Brasso-Lælias contained in the group are certainly the finest and most varied selection ever shown at one time, about 60 plants, bearing an aggregate of nearly 100 large flowers, being staged. These comprise Brasso-Cattleya Mrs. J. Leemann, B.-C. Siren, B.-C. Digbyano-Warneri, B.-C. Thorntonii, B.-C. Digbyano-Mossiæ, and its pure white variety Queen Alexandra; B.-C. Digbyano-Schröderæ, B.-C. Digbyano-Warcewiczii, B.-C. Digbyano-Mendelii, B.-C. Pluto, B.-C. Madame Hye, B.-C. Cordelia, Brasso-Lælia Helen, Brasso-Lælio-Cattleya Rowena, and others all exhibiting charming tints and variety of form. Cattleyas are shown in superb condition, the species included being C. Trianæ Mrs. Ed. Sondheim, the finest white Trianæ; some varieties of C. Mendelii, the best of which are C. M. Prince of Wales, C. M. grandiflora, C. M. May Queen, a pretty, light form; and the superb C. M., Holford's variety, bearing two flowers of great beauty, fine colour, and gigantic size. C. Schröderæ "The Baron," which secured a First-Class Certificate at the last meeting of the Royal Horticultural Society; C. S. Heatonensis, a choice, light variety; C. intermedia, Fowler's variety, the finest form of typical C. intermedia, C. Luddemanniana and C. L. alba, a fine white flower with rose-tinted lip; and C. Lawrenceana, of which a dozen strong plants are shown. Among hybrid Cattleyas, the beautiful C. Dusseldorfei variety Undine (C. intermedia alba × C. Mossiæ Wageneri), which secured a First-Class Certificate at the Royal Horticultural Society, December 11, 1906, make a fine feature, 14 plants, bearing together 43 flowers, being used. Lælio-Cattleyas almost exclusively raised at Westonbirt are in fine form, their gorgeous colours being very skilfully arranged for effect among the white and light-coloured varieties by Mr. Alexander. A grand example of L.-C. callistoglossa excelsa has a fine spike of five blooms, with intense purplish-crimson labellums; L.-C. Golden Glory (L.-C. Zephyra × C. Mossiæ Reineckiana) was a beautiful plant, bearing 26 golden-yellow flowers with crimson markings on the lip. It secured a First-Class Certificate at the Temple Show, 1907, and was illustrated in the *Gardeners' Chronicle* on June 1 the same year. Others used in the group are L.-C. Dora, L.-C. Olivia, L.-C. Elinor, L.-C. Phryne, L.-C. Wellsiana, L.-C. Ganymede (L. Latona × C. Schröderæ) in quantity, its bright bronzy-yellow and purple flowers being very effective, the variety Apricot very distinct; L.-C. Dorothy, L.-C. Pizarro, L.-C. Baroness Schröder, some brilliant orange-coloured L.-C. Hippolyta, and many of the new Westonbirt hybrids, including L.-C. Cæsar, L.-C. Crœsus, L.-C. Zoroaster variety Rex, L.-C. Lustre, Westonbirt variety, &c., together with Lælia Gwennie, L. cinnabrosa, and others.

Cypripediums included many unnamed seedlings of great promise. C. Helen H., Westonbirt variety, which received a First-Class Certificate at the last Royal Horticultural Society's meeting; C. Queen of Italy, C. Beryl, C. aureum Hyeanum, C. Chapmanii superbum, and C. Maudiæ magnificum, bearing six emerald green and white flowers. In the front of the group and at salient points, brilliant scarlet colour was given by a number of fine specimens of Sophronitis grandiflora, one of which bears 80 and another 50 flowers; fine orange-scarlet Ada aurantiaca, the deep claret-coloured Masdevallia Rocking hybrid, four plants of the richly-coloured Sophro-Lælia Phroso superba, Sophro-Cattleya Chamberlainiana, &c., and others noted were good Miltonia Bleuana, M. Roezlii, the bearded yellow Dendrobium Brymerianum, the rose-scented Bifrenaria Harrisoniæ.

Competitive Orchids.

In Class 21, for a collection of the most varied and meritorious Orchids has brought another grand exhibit in the extensive collection staged by M. Lambeau, of Brussels, which has secured the King's prize of a large Gold Medal. The group occupies the whole of the central stage at one end of the gallery.

In this, as in many other classes for Orchids, there is but the one entry, but M. Lambeau's

M. Duquesnoy, treasurer Société royale d'agriculture et de botanique de Gand.

fine collection has well merited the highest award. In the group the very fine and varied selection of beautiful Odontoglossum Lambeauianum form quite a study, the colours in rich tints of rose and purple on cream-white, and always on finely-formed large flowers, being remarkable. O. L. La Tribune is a marvellously spotted form, O. L. Helleputianum quite different and superbly marked, and others so extraordinary that Mons. Lambeau should be proud to have such a charming series under his name. Varieties of Cattleya Schröderæ and C. Mendelii are well represented, pretty white varieties appearing. The hybrids of Brassavola Digbyana are shown in profusion, the richest in rose-purple tint being Brasso-Cattleya Peetersiæ (Warscewiczii × Madame Maron), which gets two parts of C. Warscewiczii. Of the yellow-tinted B.-C., Mrs. Leemann is shown in fine variety; B.-C. Warteliæ, a secondary cross with Cattleya Schröderæ alba, is a charming flower near to C. Schröderæ, but with fringed lip, and of the same section B.-C. Reneiæ var. Surprise has a flower curiously mottled with purple. Cattleya intermedia alba has four spikes, three with six flowers each; Cochlioda rosea, C. vulcanica, and C. Noezliana were in grand specimens of many spikes of rich mauve or scarlet flowers; Maxillaria luteo-alba bears scores of fragrant blooms; the selection of Odontoglossum crispum has many blotched forms, in which the deep red or purple colour has almost obliterated the white ground colour; specially noted were O. c. coloratum and O. c. eminens, two grandly-coloured forms. O. Madouxianum was a finely-coloured bloom, and the varieties of O. ardentissimum superb, the superlative being reached by the noble O. ardentissimum Memoria Lambeauiæ at the end of the group, and which secured the medal for the finest hybrid Odontoglossum, the perfectly-formed flower being almost entirely of a deep reddish-claret with narrow white margin and tips. M. Lambeau has also secured the medal for the best seedling Odontoglossum. Miltonia Bleuana latimaculata and a fine white form of the same hybrid are grandly flowered; Angræcum citratum has many sprays of pretty white flowers, Miltonia vexillaria gigantea and other forms show that species at its best; various Odontiodas and other rare hybrids and species are represented, and white Cattleyas have with them the new C. Suzanne Hye de Crom.

On the side of the gallery, M. Maurice Verdonck, Ghentbrugge-lez-Gand, gave a most interesting exhibition in four classes, viz., Orchids of Guatemala and Colombia, Orchids of Brazil, Orchids of Central America, and Indian Orchids, securing the Gold Medal in each of the four classes with Orchids from these respective districts. Specially good in the Brazilian exhibit are the Oncidium sarcodes, O. Marshallianum, Lælia purpurata, and Cattleyas; in the Colombian group, the Miltonia vexillaria, Odontoglossums, and Masdevallias; in the Guatemalan class, the fine forms of Lycaste Skinneri, Odontoglossom Uro-Skinneri, &c.; and in the Indian, the well-grown Dendrobiums and Cypripediums and scarlet Renanthera Imschootiana. M. Verdonck has also secured the highest awards for the best 12 Dendrobiums, his collection containing the new D. Bronckartii, D. nobile virginale, D. Jamesianum, D. crepidatum, D. barbatulum, D. Devonianum, D. primulinum, and others all finely flowered; and for the best 25 Dendrobiums and the best single specimen Dendrobium.

In Class 26 (amateurs) for the best collection of 50 exotic Orchids, M. Ch. Dietrich has won the 1st prize, an Œuvre d'Art, for a very meritorious selection containing good Odontoglossums, Lælio-Cattleya Dominiana, L.-C. Capt. Percy Scott, Cattleya Louis Chaton, C. Mozart, Brasso-Cattleya Mrs. Leemann, Miltonia Bleuana nobilior, Zygopetalum Perrenoudii, Cymbidium Devonianum, &c.

In Class 27, 50 Orchids (nurserymen), M. Emile Praet, Mont St. Amand, Ghent, has secured the 1st prize with a very fine lot of varieties of Cattleya Schroderæ and C. S. alba; Odontoglossums, including good varieties of O. crispum, O. Lambeauianum, O. Rolfeæ, Cattleya Lawrenceana, Phalænopsis Schilleriana, Cypripediums, &c.

Class 28, for the best collection of 30 Orchids, M. Théodore Pauwels, Meirelbeke Gand, has been awarded the 1st prize for a good group, in the centre of which is an enormous specimen of a light-coloured Cattleya Mendelii covered with flowers; good C. Trianæ, C. Lawrenceana, C. Skinneri, and other Cattleyas and Lælias, Angræcum sesquipedale, Dendrobiums, Masdevallias, &c.

Cypripediums are not well represented. In the class for 25 (amateurs), M. Maes-Braeckman, Ghent, has secured the 1st prize; in the similar class for nurserymen, Messrs. Janssens & Putzys, Merxem, the 1st prize with a selection containing a very interesting series of varieties of C. aureum; the 2nd prize going to M. Pynaert van Geert, Ghent, for a very varied selection of well-flowered plants; the same firm taking the 1st prize for a collection of Anæctochilus and allied plants.

M. De Vincke Dujardin, Bruges, has secured an Œuvre d'Art for a very fine exhibit, including a remarkable selection of Cattleya Mossiæ in great variety of tint, one form having a distinct slate-blue veining on the lip, and others of the C. M. Reineckiana and C. M. Arnoldiana being very pretty. The whole are characterised by good, broad labellums and broad petals. C. intermedia alba and other Cattleyas, Brasso-Cattleya Digbyano-Schroderæ, B.-C. Madame Maron and other Brasso-Cattleyas, a very fine variety of Lælio-Cattleya Schilleriana and some other Lælio-Cattleyas, Lælia anceps alba, and other showy varieties are included.

For the best collection of 50 Odontoglossum crispum, M. A. Muesser, of Brussels, has secured the 1st prize for a nice selection of plants arranged beneath the dome.

In Class 67, for the best group of 12 Odontoglossums raised from seeds, M. Graire, of Amiens, has secured the Gold Medal with a very handsome lot, which included O. ardentissimum Empress of India, a magnificent form with a clear mauve-purple blotching on the inner parts of the broad segments, the margins and tips being white; O. ardentissimum Cavour, a finely-marked flower; several superb forms of O. crispum raised from seeds, and all fine, well-marked flowers. Two plants of the deep blood-red Odontioda Devossiana are also in the case, and which, by an oversight, were not placed before the jury.

A very remarkable exhibit is the enormous specimen of Cattleya Lawrenceana var. Royale de Laeken (gr. M. J. de Bievre), from the gardens of His Majesty King Leopold. The plant was bought as a very small specimen from the first importation, and as now shown it bears 85 finely-coloured flowers.

Messrs. Charlesworth & Co., Heaton, Bradford, has staged a good selection, including a very fine form of the red-tinted Odontioda Vuylstekeæ, O. Bradshawiæ of a clear orange-scarlet tint, O. Keighleyensis, a grand form of Odontoglossum ardentissimum, O. sceptrum aureum, O. crispum Prince George of Wales (a grandly-blotched variety), Vanda lamellata, Miltonia Bleuana virginale, &c.

M. A. A. Peeters, Brussels, has been awarded an Œuvre d'Art for an excellent group of new and rare Odontoglossums, which include O. ardentissimum Cooksonianum and O. a. Evansianum, two superbly-coloured forms of fine shape; O. Fascinator Souvenir du Centenaire (a large and densely-spotted flower), and O. crispum Bijou d'Ucele, a distinct white flower heavily blotched with red-brown.

M. Th. Paewels has secured a Gold Medal for a magnificent lot of 50 plants of Cattleya Lawrenceana.

M. Emile Praet shows 25 forms of Cattleya Schröderæ.

M. Theodore Paewels shows the best Vanda in his fine albino V. suavis pallida.

Messrs. Hugh Low & Co., Enfield, exhibit a small selection of varieties of Cattleya Mendelii, one very large form having a broad and finely-coloured lip.

M. Van de Putte has staged a very fine group of good Lycaste Skinneri.

Masdevallias are shown by M. de Hemptinne, who won the 1st prize for the best with an enormous plant of M. Pourbaixii, and various other exhibitors contributed other interesting Orchids.

Stove Plants.

The ornamental-leaved stove plants are arranged in imposing groups in the great hall of the Casino, as on previous occasions. The best group of 25 plants, with marbled, striped, or coloured foliage, is shown by the Société Anonyme Horticole Gantoise, Ghent, and contains handsome specimens of the following varieties amongst others:—Helicomia illustris, Pandanus Veitchii, P. Sanderiana, Spathiphyllum picturatum, Philodendron Mamei, Codiæums (Crotons) M. Charon and Countess, Caladiums Mistress Laing and Raymond Lemonnier, Aglaonema Roebelinn, Alpinia vittata, A. Sanderiana, Alocasia Martin Cahuzac, Dieffenbachia Fournieri, D. nobilis, Phyllotænium Lindenii magnificum, and Pavetta borbonica. An excellent collection is also shown by the Société Anonyme Louis van Houtte, père, Ghentbrugge, containing a very fine specimen of Leea amabilis superba. This has been awarded the 2nd prize, and the 3rd prize was gained by M. Hippolyte Millet-Richard, Ledeberg.

The 1st prize in a smaller class for a collection of 22 plants has been won by M. Alexis Dallière, Ledeburg, and this exhibit also contains very beautiful specimens, indicating first-rate cultivation; 2nd, M. H. Millet-Richard, Ledeberg.

For a collection of 15 Sonerillas and Bertolonias, the 1st prize has been awarded to the Société Anonyme Louis van Houtte, père, whose excellent collection of these beautifully-marked plants is accommodated in a glass frame. All the plants are of very high cultivation, but especially the varieties Madame Bleu, Marmorata, Madame Leon Say, and Souvenir de Gand.

Marantas and Calatheas.—The exhibits of these former favourites are not quite so extensive as on former occasions. Nevertheless, there are some magnificent single specimens dotted here and there over the show, M. Draps-Dom, of Laeken, and M. Jacob-Makoy, of Liege, sharing the chief honours in the way of prizes, M. Draps-Dom being awarded a Gold Medal for the best group of 20 plants; and M. Jacob-Makoy a Gilt Medal for the best group of 10 plants.

Codiæums (Crotons).—There are some remarkably fine Crotons in the show, and the brilliant colouring and marking of the foliage adds a brightness to the exhibition, notwithstanding the changing lights and shades by passing clouds and showers. There were classes for 50, 25, and 12 plants, the winners of the 1st prizes in these classes being: M. Delaruye-Cardon (Œuvre d'Art); Société Gantoise (Gold Medal); and M. Alex. Dallière (Gold Medal).

Bromeliads.—Most of the plants have their flowers still unopened. Tillandsias (Vriesias) are the principal kinds shown, the only competitors being M. J. Moens, Lede, who has won a Silver Medal for the finest plant not in flower, and M. Poelman, St. Amand, for the best plant in flower. (Silver Medal).

Anthuriums.—Ghent nurserymen have always been famous for these brilliant aroids, and on this occasion they probably surpass all previous efforts, judging by the size and number of the specimens shown. It is impossible to describe in detail the merits of particular varieties, but they varied from the purest creamy enamel to the deepest shiny crimson; while many of the Scherzerianum seedlings are remarkable for their curly spadices and their brilliant, self-coloured or speckled spathes, hanging down like miniature flags. For the best collection of 25 Anthuriums in flower M. A. de Smet has secured the 1st prize, the 2nd prize (Gold Medal) going to the Ecole Royale de Pomologie et d'Horticulture; the 3rd (a Gold Medal of less value) to M. de Smet-Duvivier. The varieties shown are chiefly of A. Scherzerianum, A. Andreanum, and A. crystallinum.

Other prize-winners in this section include M. Maes-Braeckman, who has won a Gold Medal for Scherzerianums; while M. A. de Smet has secured the Gold Medal for speckled varieties in two classes, and medals in several others.

Palms.—Without Palms the Ghent show would look bare indeed. There were specimens of all sizes, not always in their classes, because often they were required to produce an effect as background in the buildings. The Kentias, Cocos, Phœnix, and Arecas naturally predominate, but these are well backed up with Rhapis, Livistonas, &c. For the best collection of eight Cocos, M. Jules de Cock has secured the Gold Medal; while M. van Laethem and MM. de Reusse Frères has been awarded Gilt Medals for single specimens. For the best group of eight Kentias the 1st prize has been awarded to the Société Anonyme Horticole "Flandria," Bruges, and the 2nd prize to M. G. Wibier, the plants in both cases being fine specimens; while those winning the 3rd prize of a Gilt Medal are smaller plants, from M. F. Tollenaere.

Cycads and Pandani.

Ten classes were allotted to this section, and all are filled but two. For the best lot of 12 Cycads, M. de Ghellinck de Walle, Wondelghem, has secured the 1st prize. He has some splendid specimens in his group, including Zamia horrida, Z. Vroomii, Lepidozamia Denisonii, and L. Macleayi.

For the six best Cycads, MM. de Smet, Frères, Ledeberg, have secured the Gold Medal valued at 100 francs.

There is a strong competition with Cycas revoluta. The 1st prize has been won by M. Ed. de Beule, Sinay, and the 2nd by MM. Eckhaute et Fils, St. Denis Westrem.

MM. de Smet, Freres, have easily secured the Silver-Gilt Medal as the 1st prize for a remarkable Zamia.

For a collection of 10 Pandani, the Gold Medal has been awarded to M. Pynaert van Geert, Ghent, his specimen of P. Sanderæ being particularly fine.

The Gilt Medal for the best Pandanus has been won by M. Delaruye-Cardon, Ghent, the second prize going to M. Pynaert van Geert for a fine specimen of the green and narrow-leaved P. caricosus.

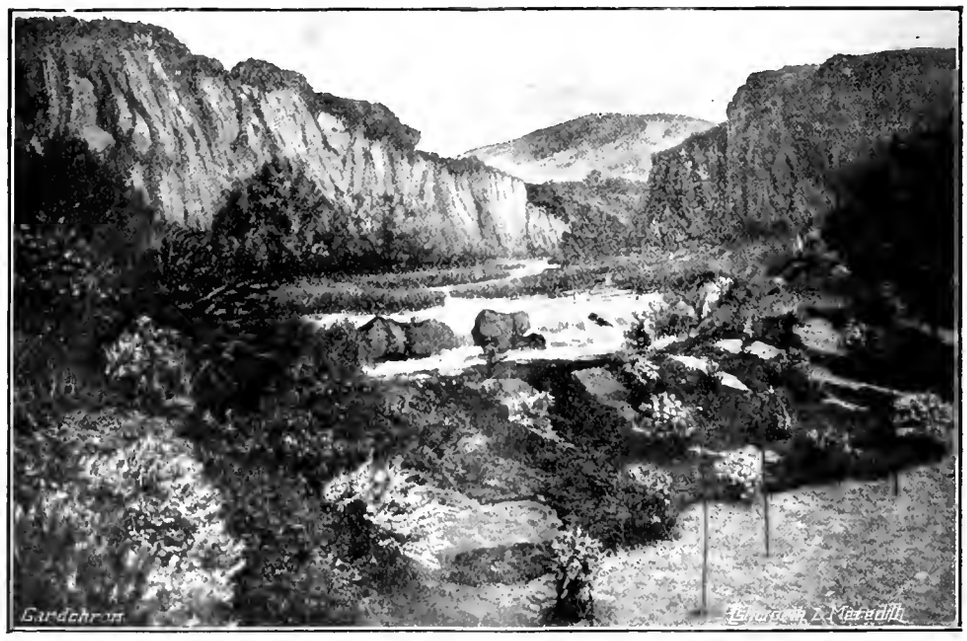

Fig. 128.—Exhibit of New Holland plants at the Ghent International Exhibition, with painted background representing natural scenery.

Ferns.

More than 30 classes were set apart for Ferns, and, on the whole, the plants brought together are good examples of cultivation and beauty. For the finest tree Fern, M. de Smet, Frères, have been awarded the Gilt Medal for a fine Dicksonia princeps, the second prize going to M. de Ghellinck de Walle.

In the same section, for amateurs, M. Maurice Duquesnoy, Ghent, has obtained the 1st prize, M. de Ghellinck de Walle, the 2nd prize, and the Ecole d'Horticulture de l'Etat, Ghent, the 3rd prize.

For 30 Ferns, M. Jules de Cock, Meirelbeke, has won the first prize, with the congratulations of the Jury, his Nephrolepis Forsteri being particularly good. M. Pynaert van Geert has secured the Gold Medal as 2nd prize, also with the felicitations of the judges.

M. de Ghellinck de Walle has been awarded the Gold Medal as the 1st prize for

a collection of 30 exotic Ferns, including good specimen Davallias, Polypodiums, Nephrolepis, &c. In the trade group, MM. Duriez, Frères, Wondelgem, has secured the 1st prize.

A very fine example of Todea superba from M. Louis van Houtte, Frères, secured the 1st prize of a First-Class Silver Medal, with the felicitations of the Jury.

Many other Ferns are exhibited, perhaps the most remarkable being a collection of 40 Selaginellas from M. Ghellinck de Walle, to whom the 1st prize of a Gold Medal was deservedly awarded.

Tree Ferns, including Cyatheas and Dicksonias figure in a few classes. M. Arthur de Smet and MM. Duriez, Frères, secured 1st prizes.

The Lomarias and Davallias were rather below the average in size and culture, and the same might be said of Adiantum Farleyense and the Platyceriums. A fine Nephrolepis, however, from the École d'Horticulture makes up for the absence of many smaller plants, and it easily secured the 1st prize.

Begonias

In a class for the most beautiful Begonia (tuberous-rooted or arborescent) a new species named B. Binoti was shown by MM. Chantrier, Frères, Mortefontaine, Plailly (Oise). This plant was discovered by M. Binot in Brazil. It has thick, fleshy leaves of very delicate texture, measuring about 1 foot across, wrinkled, with white veins, and covered over the whole surface with short, erect hairs. The leaves have a glossy appearance, are green in colour, and may be said to resemble an Anthurium more than a Begonia.

Greenhouse Plants.

Some remarkably fine plants are displayed in the classes composing this group. Probably the very finest in the show is the class in which prizes for 40 miscellaneous plants are competed for, and in which the prizes were offered to Belgian exhibitors by the English Committee, which had been appointed in honour of the memory of M. Louis Van Houtte, Père. In this class the 1st prize has been awarded to the Société Anonyme Horticole Gantoise with the "felicitations de Jury." Plants such as Davidsonia pruriens, Pritchardia grandis, Anthurium Veitchi, Heliconia illustris, and others being first-class examples of their kind. The 2nd prize of a Gold Medal, valued at 200 francs, has been awarded to the Société Anonyme Louis van Houtte, père, in whose collection there are also some very fine specimens. The same firms are in competition for a group of 20 similar plants, the struggle resulting in the same order.

For 20 ornamental foliaged plants, the Société Anonyme Horticole Gantoise has secured the 1st prize, the 2nd prize going to the firm of Louis van Houtte, père. Those are some magnificent Aroids, Palms, Crotons, Marantas, &c., in these two groups.

For 12 ornamental unflowered plants, MM. Duriez, Frères, has secured the 1st prize, the exhibit being largely composed of fine Arecas, Rhapis, Latanias, &c. An old friend in the form of a fine basket of plants of Saxifraga sarmentosa superba tricolor is exhibited by M. Morabe, Ghentbrugge, who won the 1st prize of a Silver Medal, the 2nd prize (a second-class Silver Medal) going to M. Schepens de Baets.

Flowering Stove and Greenhouse Plants.

There is not quite so many of these as one would have imagined, although every chance had been made in the schedule for a large representation.

One collection of 20 Clivias from M. V. de Bisschop, Tronchiennes, has secured the 1st prize of a Gold Medal, valued at 100 francs,

Fig. 129.—Odontoglossum wilckeanum imperiale, as shown at the Ghent International Exhibition in Major Holford's collection.

the 2nd prize, a Gold Medal worth 50 francs, going to M. Ch. Vermeire, of Ghentbrugge. A few other Clivias as single specimens and groups of 6 or 12 plants are shown, the 1st prize winners being MM. Bier et Ankersmit, Melle; M. A. Gallet, Ghent; and M. Vict. de Bisschop.

A Gilt Medal has been awarded to MM. Bonfiglioli et fils, of Bologne, for 20 Gardenias, which, however, are poorly flowered, although finely grown plants.

Acacias, Genistas, Cytisus, Brachysemas, and other plants from the Cape and Australia constitute a very important feature of the show, and there are some remarkably fine specimens, such as used to be seen in England 30 or 40 years ago. One of the most successful exhibitors of these plants is M. Firmin de Smet, of Vinderhaute, who exhibits some good specimens of culture; and M. Jules de Cock, M. Aug. Cornelis, and M. Em. Collumbien, all of Meirelbeke.

For 20 plants of Boronia elatior, finely-grown bushy plants, M. Theo. Piens, Melle, has secured the 1st prize; and M. Auguste has received a similar award for 20 plants grown as standards on stems at least 18 inches in height, although they are a long way from being in full blossom.

Greenhouse Flowering Plants.

In this section most of the plants are natives of the Cape or Australia, the principal genera represented being Acacias, Boronias, Chorizemas, Clianthus, Correas, Cytisus, Diosmas, Epacris, Ericas, Genetyllis, Grevilleas, Leptospermums, Polygalas, Sparmannias, and a few fine plants of Strelitzia Reginæ. In the various classes, M. Firmin de Smet almost swept the board, and, considering the size, culture, number and variety of his collections, he well deserved the awards for his enterprise.

Bulbous and Tuberous-rooted Plants (Greenhouse).

The most important class in this section was one for 75 Hippeastrums, and it contained two exhibits. Both were meritorious groups, but the better was one from Messrs. R. P. Ker & Sons, Aigburth Nurseries, Liverpool. This collection was remarkable for the distinct colour to be seen in the flowers, many of the tints being novel and pleasing. The 2nd prize was obtained by an exhibit from the Establishment "Labelliflos," Voorschoten.

The 1st prize in the class for 40 plants was also won by Messrs. R. P. Ker & Sons, and the 2nd prize by the Société Anonyme Horticole, L. van Houtte, père. A very large, crimson-flowered variety named Mephistopheles, shown by Messrs. Ker, was exceedingly fine.

Mr. R. W. Ker offered prizes in classes for 25 new varieties of Hippeastrums, in one case the competition being restricted to amateurs, and in the other open for nurserymen. There was no entry in the amateurs' class, but in the other class, the 1st prize was awarded to the Société Anonyme Horticole, L. van Houtte, père, for a very fine collection of choice varieties.

Messrs. R. P. Ker & Sons won the 1st prize for six new Hippeastrums, all of them having brilliantly coloured flowers of the best form; the 1st prize for six new varieties with white flowers, showing Silver King, Silver Queen, Snow Queen, White Lady, Purity and Albescens; and for the best single Hippeastrum of recent introduction.

Cyclamens.

Cyclamens were shown in several classes reserved specially for these greenhouse flowering plants. The best group of 100 plants of C. latifolium and varieties was shown by M. Ad. D. Houdt, Ghent, and the best group of 50 plants by M. D. Daarduse, Aalsmeer, who had also the best group of 25 plants, and the best group of Cyclamen of the "Papilio" type.

Forced Trees and Shrubs.

These probably form the poorest feature of the show. The plants are scarcely in blossom, and are more or less diminutive in size. Many amateurs entered in this section, and perhaps owing to the wretchedly cold weather that has prevailed, they have been unable to bring their plants to perfection for this show. Special mention, however, may be made of a well-flowered specimen of Deutzia Lemoinei compacta, shown by M. V. Vermeersch, of Evergem. The Wistarias, Prunus, Magnolias, &c., are in a backward state, but the Lilacs from M. P. de Vries, Aalsmeer, form a very attractive group.

Hardy Herbaceous Plants, &c.

These were scarcely noteworthy, and there is little doubt that some of the collections shown so regularly at Vincent Square would come as a complete revelation to our Belgian friends. A few varieties of Polyanthus, from MM. Vilmorin, of Paris, are almost all that were shown in this section. Attached to these are some very fair specimens of Primula obconica in various shades of rose, and a few forced Stocks.

Zonal Pelargoniums are also not particularly strong, the best collections coming from M. J. de Hemptinne, to whom a Gilt Medal was awarded in two distinct classes; and another medal for ten varieties to M. F. Wilryck Nagels, les Anvers.

Carnations.

These are contributed by Messrs. Hugh Low & Co., of Bush Hill Park, Enfield, in a non-competitive but very attractive group; while Mr. Engelmann, of Saffron Walden, secured the 1st prize in two distinct classes.

CINERARIAS.

A few groups of these are shown, the best being from MM. VILMORIN, of Paris, who displayed in two sections plants of the polyantha and hybrida form, and won the Gold Medal. M. FERARD, of Paris, won a Gilt Medal for a group of 40 plants; and M. WAROCQUE (of Orchid fame) has secured the 1st prize (Gilt Medal) for 20 double-flowered plants, the 2nd prize for these curious-looking things going to M. DE SAEGHER.

RHODODENDRONS AND AZALEAS.

The Ghent Shows invariably owe much of their attractiveness to the large displays of Rhododendrons that are always displayed in the temporary building. On the present occasion the varieties of Rhododendron indicum are massed together in great beds on the ground level and on slopes in the portion of the building nearest to the entrance. The plants are in pots, and the pots are placed on the surface of the ground, but the effect is that of beds planted as they would be in the flower garden or pleasure ground, and care is taken to ensure that the masses of flowers are kept well below the line of sight, in order that their effect shall be as good as possible.

All the varieties of R. indicum are termed Azaleas at this show, and we therefore retain the name for the sake of easy reference.

A very large class is that for the best exhibit of Azalea indica of any type or size, and arranged for decorative effect on a space not exceeding 50 metres. The exhibit which has gained the 1st prize was one from M. AUGUSTE HAERENS, Somerghem, and the Jury awarded the prize with acclamation, the collection being of very high quality. The 2nd prize has been won by M. RAPHAEL VERVAENE, Moerlebeke.

In the next class the exhibits consist of 40 plants, representing large specimens, and the 1st prize, valued at 500 francs, was offered by the General Secretary, M. Albert Ceuterick. This was awarded to M. D'HAENE, Nurseryman, Ghentbrugge, for a fine collection, consisting of plants about 3 to 4 feet high, and measuring from 4 to 6 feet across. Messrs. SANDER & SONS, who were awarded the 2nd prize, had also an exhibit of high merit.

In the class for 20 plants larger specimens are exhibited, and the 1st prize has been gained by the SOCIÉTÉ HORTICOLE D'HAENE, Ghentbrugge, the 2nd prize by MM. MAENHOUT, BROTHERS, Mont St. Amand, and the 3rd prize by M. AUG. VAN DAUMME, Loochristy.

It is obvious that the system of training Azaleas as pyramids is now only practised on rare occasions in the Ghent district. A class was provided for 25 plants trained in this manner, but the exhibits are not numerous, and the plants are small. The best collection of 25 plants is shown by Messrs. F. SANDER & SONS, and M. CHARLES VUYLSTEKE has obtained a 1st prize for 12 plants. In a class for 100 plants (pyramids) M. VICTOR VANDE WEGHE, Loochristy, has obtained the 1st prize. The best group of 12 single-flowered Azaleas came from the SOCIÉTÉ ANONYME HORTICOLE A. D'HAENE, and the best dozen double-flowered varieties from M. AUG. HAERENS, Somerghem. In this latter exhibit the best varieties were Ernest Eckhaute (red), Elborina plena, and Madame H. Seidée (white).

A very important class is that for 100 varieties of Azalea indica, the exhibits in which make a very glorious display. The specimens are generally dwarf, and have a diameter varying from 3 to 5 feet. The prizes have been gained in this order: 1st, The SOCIÉTÉ ANONYME HORTICOLE A. D'HAENE; 2nd, The SOCIÉTÉ ANONYME HORTICOLE DE MONT ST. AMAND; and 3rd, The SOCIÉTÉ ANONYME LOUIS VAN HOUTTE, PÈRE, The winners of the 1st prize in the class just described have also been awarded the 1st prize in a class for 50 plants.

The best collection of 100 varieties of Azalea indica which have never been previously presented at an exhibition of the Society, was shown by Messrs. F. SANDER & SONS. Most of these plants were in pots 3 or 4 inches in diameter, and, being very small specimens, the flowers in some cases appeared exceedingly large, whilst the colours were attractive and brilliant. Greatest prominence was given to a variety named Centenaire, with clear red, semi-double flowers of large size. Other attractive varieties included Sylvia (deep red), Leda (white), Thalia (white), and Juno (pink). The 2nd prize was gained by Messrs. AUGUSTE HAERENS.

The SOCIÉTÉ ANONYME HORTICOLE A D'HAENE has obtained the 1st prize for 100 plants in five varieties, and to be shown in pots not exceeding 0m 60 in diameter.

A somewhat novel effect is produced by the exhibits in a class for 50 plants of Azalea indica cultivated in the form of espaliers. The plants shown by M. AUGUSTE HAERENS are about 2 feet or so high, and present two nearly flat surfaces, the effect being as good when seen from one side or the other. Such a plant might be suitably placed in the middle of a dwelling-room, but those exhibited by the SOCIÉTÉ ANONYME LOUIS VAN HOUTTE, PÈRE, had generally but one good side, and are therefore suitable for use as screens only.

The best exhibit of 50 plants of a double, red-flowered variety came from M. WILLE-TEMMERMAN, who showed the variety Ernest Eeckhaute in very dwarf plants abundantly flowered.

The variety Julius Roehrs was shown by Messrs. F. SANDER & SONS, this exhibit being the only one forthcoming in a class for 25 plants. The variety has double flowers of extra large size, which, in colour, are of a soft but rich shade of red.

An excellent exhibit was made by MM. DE REUSSE, BROTHERS, Saffelaere, in a class for 50 plants of single and double-flowered Azaleas (pink). A large selection of varieties was shown, and two of the most effective were Prof. Wolters and Paul Weber.

The best lot of 25 plants of Azalea indica "Hexe" was shown by M. PYNAERT VAN GEERT, and this brilliant red variety being placed in juxtaposition to the variety "Vervaeneana alba," the effect was most marked. For this latter variety, which has large, semi-double, white flowers, the best exhibitor was M. AUGUSTE HAERENS, Somerghem, and he was followed by M. JOSEPH VERVAENE, Ledenberg.

In a class for 12 new varieties of Azalea indica Messrs. HAERENS & WILLE, Somerghem, have obtained the 1st prize for an exhibit in which we noted the following sorts as the most valuable: American Beauty (red, double), Mlle. Marie Antoinette (reddish-pink, single), Bay Ridge (white, double), Snowflake (white, double), and Virginal (white, double). In the 2nd prize exhibit Messrs. F. SANDER & SONS have a very fine double red variety named Major Holford.

In a class for six varieties that are not yet in commerce there are several novel shades of colour to be seen; there are La Madone (puce-purple), Centenaire (orange-red), and M. Pierre de Bielde (dull purplish-red).

The exhibits of Camellias are very good in some instances, but they do not call for special remark.

In a few classes there are groups of Azalea mollis or Rhododendron sinense; but, taken together, they are not of special quality. Some of the most remarkable are to be seen in a class for 25 plants, the specimens exhibited being standards from M. CHARLES VUYLSTEKE.

The method of arranging the hardy Rhododendrons on slopes is most excellent. The visitor approaches them as he would a carefully-planted Rhododendron garden, and the effect is one of a bank of flowers, for it matters not what height the plants may be, they are so arranged that every plant contributes its proper share to the general display. The best collections of 40 plants and 20 plants are shown by M. PYNAERT VAN GEERT, and in each case he was followed by the SOCIÉTÉ ANONYME HORTICOLE LOUIS VAN HOUTTE, PÈRE.

M. VALENTIN VERMEERSCH, Evergem, had a very fine exhibit in a class for 25 plants, and M. SPAE-VANDERMEULEN, Ghent, has won the 1st prize for 10 plants.

In a class for 30 Rhododendrons of new or little-known varieties shown by M. JEAN BRACKE, Loochristy, who has gained the 1st prize, we remarked excellent varieties in President Callier (mauve with dark spotting), M. Dierman, and Fritz Dobbelaere.

M. PYNAERT VAN GEERT has won the 1st prize in a class for 75 Rhododendrons in three varieties; and M. CHAS. VUYLSTEKE the 1st prize for 12 plants of Rhododendron "Pink Pearl." This variety, so familiar in England, especially at the "Temple" Show, is exhibited in very praiseworthy condition.

DRACÆNAS.

In addition to the Cordylines shown numerously in the groups and as specimens indoors, there are some interesting exhibits of D. Doucettii, D. indivisa, and similar species out-of-doors, where the Conifers and large plants of Sweet Bay are the most conspicuous features. The variation to be seen in D. indivisa are remarkable, and those with very broad leaves, in which the midrib is coloured more or less red, are excellent garden plants.

CONIFERS.

Most of the Conifers exhibited were planted out in the form of shrubberies in the "French" garden dividing the Casino buildings from the annexe. The largest groups were shown in Class 660, the exhibits being of 50 plants. An excellent collection was shown by the SOCIÉTÉ ANONYME HORTICOLE DE CALMPTHOUT, which was awarded the 1st prize and was highly commended by the jury.

The best collection of 25 specimens was shown by M. C. KERKVOORDE, Wetteren, and the best collection of 20 dwarf-growing Conifers by the SOCIÉTÉ ANONYME HORTICOLE DE CALMPTHOUT. There was only one exhibit in a class for 15 new varieties of Conifer, this being from the SOCIÉTÉ ANONYME HORTICOLE L. VAN HOUTTE, PÈRE. Other 1st prizes for hardy Conifers were won by the SOCIÉTÉ ANONYME HORTICOLE DE CALMPTHOUT and M. AUGUSTE VAN HEDEN.

There were several classes exclusively for Araucarias, in one of them each exhibit consisting of 25 specimens of tender varieties. The 1st prize in this class was won by M. HARTMANN, Mond St. Amand, whose collection was much commended by the Jury, and the same exhibitor was awarded the 1st prize for 15 tender varieties of Araucaria.

M. AUG. VAN HEDEN won the 1st prize for six specimens, and there were several additional classes for single specimens.

CACTI.

In some of the glasshouses erected by horticultural builders out-of-doors some interesting exhibits of Cactaceous plants are made, particularly by M. FRANZ DE LAET, Contich Nurseries, near Antwerp, who was awarded several 1st prizes.

MAJOR HOLFORD'S HIPPEASTRUMS.

Apart from his great group of Orchids, probably the finest exhibit in the show, was the display of Hippeastrums (not for competition) of the Westonbirt strain staged by Major G. L. HOLFORD, C.I.E., C.V.O. (gr. Mr. Chapman). This was probably the most remarkable and beautiful collection of these flowers ever displayed, the great number of plants in the group being of the very highest order of merit in all points. Specially noteworthy were the bright-scarlet and deep-red varieties, although the white and light-coloured forms were equally beautiful.

The following varieties were of outstanding merit:—Harvest Home (a very large, well-formed flower, nearly white), King Arthur (crimson self), Rubens (rich orange red), Harlequin (white, with bright red stripes), Marmion (white, with rose stripes), and Apollo (glistening white, with scarlet markings). A Gold Medal was awarded.

EXHIBITS FROM HORTICULTURAL JOURNALS.

Amongst the numerous non-competitive exhibits, to which we are unable to refer in detail, are several collections of illustrations of plants, garden scenes, &c., contributed by the proprietors of horticultural journals. It may interest readers to learn that the highest award of a Silver-Gilt Medal was awarded to the *Gardeners' Chronicle*, and Silver Medals were awarded to *La Tribune Horticole* and the *Revue d'Horticulture Belge et Etrangers*.

THE FIRST EXHIBITION.

In the interior of the building built to represent the old inn "Frascati" (as described on p. 283) the following plants had been got together by Mons. VICTOR HEURSEL DE MEESTER, Curator for the Society, who has been awarded a prize consisting of an Œuvre d'Art:—Sparmannia africana, S. africana fl. pl., Acacia melanoxy-

lon, A. lophantha, A. lineata, A. (semis), A. Bertiana, A. (semis), A. linifolia, A. suaveolens, A. verticillata robusta, A. grandis, Eugenia myriophylla, Ligustrum japonicum aurea elegantissima, Rhododendron Sesterianum, Hedychium Gardnerianum, Rondeletia (Bogiera) cordata, Leptospermum Scoparium (bullatum), Homaranthus (Carumbium) populifolius, Roupala Pohlii (corcovadensis), Nerium oleander, Strelitzia Reginæ, Chorizema ilicifolia, Erica herbacea, Sollya heterophylla, Diosma ericoides alba, Semele (Ruscus) androgyna, Alpinia nutans, Cestrum (Habrothamnus) elegans, Melianthus major, Ceratonia siliqua, Abutilon Thomsonii Souvenir de Bonn, Coprosma Baueriana variegata, Asparagus Sprengeri, Feijoa Sellowiana, Polygala Dalmaisiana grandifolia, Grevillea robusta, Edwardsia macrocarpa, Zieria Smithii, Eriobotrya japonica, Hedera Helix arborescens, Schinus molle, Cestrum (Habrothamnus) Newellii, Eucalyptus globulus, Abutilon megapotamicum (vexillarium), Brachysema lanceolatum, Cacti, Doryanthes Palmeri, Eupatorium deltoideum, and Lopezia miniata. These plants are of those species that were shown at the first exhibition the Society held on February 7, 8, 9 & 10, 1889. In cases where the plants exhibited are not in flower, black and white or coloured drawings have been attached to them. It is a very interesting exhibit.

THE LUNCH.

A lunch was offered to the members of the Jury at 2 o'clock on Friday in the Great Hall of the "Halle aux Draps." There were 300 guests, and the tables were prettily decorated with flowers.

The President, M. A. Callier, thanked the members of the Jury who had accepted the invitation of the Society to visit Ghent on the present occasion. He thought all would say that it is impossible for the Society to do better than it has done, but that it had arrived at its highest point of usefulness. But the success of the present was the warrant of the future. Ten years ago Count de Kerchove thought also that nothing better could be done, but progress had since been made. One could estimate the distance traversed by the Society upon comparing the plants exhibited at the first exhibition in 1809 and the Orchids shown now by M. Vuylsteke. After the lapse of another five years the next exhibition will have a special character, and it will occupy more room and a better place, as it will be held in connection with the great International Exhibition of Ghent of 1913. The President concluded by proposing the toast of "The Jury," coupling this with the name of the Honorary President of the Jury, Lord Redesdale, and the President, M. Viger.

Lord Redesdale thanked M. Callier, and he said how he was delighted again to be in the hospitable town of Ghent, the queen of horticultural towns in the world. When he went back to England five years ago he said that the last word upon horticulture had been said. But the present exhibition was far better than the last one. The horticultural riches are a revelation of the beauty which can be obtained by human science. Lord Redesdale called special attention to the Orchids shown by M. Lambeau, and, as an Englishman, he was proud of the plants exhibited by his countryman, Major Holford.

M. Viger called attention to the activity and the energy spent by the committee of organisation. He thanked the exhibitors and the committee of organisation of the exhibition, MM. Ceuterick, General Secretary, Lucien de Cock, Assistant Secretary, Arthur de Smet, who had charge of the hall, E. Wartel, who had charge of the winter garden, and Romain de Smet, who had charge of the saloons. He drank to the prosperity of the Society and to his staff.

M. Ceuterick spoke of the Committees which have superintended the work of the Society since 1808, and referred to the late Count de Kerchove, M. Fierens, and M. de Meulenaere, who prepared the whole work of the centenary exhibition. He offered his thanks to the horticultural Press, which had greatly helped the Committees.

FIG. 130.—PHILODENDRON ILSEMANII, HORT. SANDER, AS SHOWN AT THE GHENT INTERNATIONAL EXHIBITION. (See p. 257.)

SOCIETIES.

ROYAL HORTICULTURAL.

APRIL 28.—The weather conditions at the meeting of the committees held on this date were most unfavourable. Very heavy rain was falling, but inside the Hall there was a bright display of flowering plants, including Orchids, forced flowering shrubs and trees, Roses, bulbous plants—amongst which were many choice groups of Narcissi and Tulips—Carnations, and a host of seasonable hardy flowers. The Orchid Committee granted several awards to novelties, including one to an Odontoglossum, shown by DE B. CRAWSHAY, Esq. The Floral Committee granted three Awards of Merit to new plants, but no novelty was forthcoming before either the Fruit and Vegetable or the Narcissus Committees. In conjunction with the ordinary

meeting of the society, the National Auricula Society held their annual exhibition, a full account of which is given in our report below.

At the afternoon meeting 37 new Fellows were elected and a lecture on the Profession of Landscape Gardening was given by Mr. E. White.

[Owing to pressure on our columns we have no space to publish a report of the Committees. This will be given in our next issue.]

Floral Committee.

AWARDS OF MERIT.

Hippeastrum Purity.—This is a white-flowered variety that has already been exhibited, and as its albino character appears fixed, for it is now three years since it was first shown, the Committee granted it this distinction. It was shown by Mr. C. R. FIELDER, the raiser of Snowdon, a variety that has since developed a slight rose tinting.

Aubrietia Lavender.—A variety of this floriferous spring garden subject of the shade of colour indicated by its name. The flowers are rather larger than those of Dr. Mules, and they completely cover the foliage beneath them. Shown by Mr. PRICHARD, Christchurch, Hants.

Auricula Phyllis.—An Alpine of mauve and purple shading, with a cream centre of perfect outline and correct breadth. The rich purple colouring shades to a pleasing mauve tint. Shown by Mr. J. DOUGLAS, Great Bookham.

Orchid Committee.

AWARDS.

FIRST-CLASS CERTIFICATE.

Odontoglossum crispum "Queen of the Earth," from DE BARRY CRAWSHAY, Esq., Rosefield, Sevenoaks. A very beautiful Odontoglossum, first illustrated and noted in the *Gardeners' Chronicle*, May 19, 1906, p. 309, when the fact that many experts doubted the accuracy of its description as a true O. crispum was recorded. Its flowers now produced vary very considerably from those borne by the plant when illustrated, the colour having become more red, and spread over the greater part of the sepals and petals. The heavy blot hing on the finely-formed flower is reddish-claret colour.

AWARD OF MERIT.

Odontoglossum platychcilum superbum, from Sir TREVOR LAWRENCE, Bart., K.C.V.O. (gr. Mr. W. H. White). A very interesting species from Guatemala, of which a single plant appeared and was illustrated in the *Gardeners' Chronicle*, May 7, 1892, that form having white flowers with rose spots on the labellum. The present plant bore seven spikes, generally two-flowered, and pink in colour, spotted on the lip with rose.

Cirrhopetalum Wendlandianum, from Sir TREVOR LAWRENCE, Bart. The plant bore a head of five flowers, each about 5 inches in length, yellow striped, and tinged with red, the dorsal sepals and petals being fringed. It resembles C. Collettii, but has narrower flowers and differs in colour.

Aerides Vandarum, from Mrs. BEVINGTON, Sevenoaks (gr. Mr. Huxley). The well-known terete-leated species, with blush-white flowers.

Odontoglossum nævium, from Messrs. ARMSTRONG & BROWN. An elegant little species from New Granada. Inflorescence about a foot high, branched, flowers white with reddish spots.

BOTANICAL CERTIFICATE.

Cirrhopetalum Roxburghii, from Sir TREVOR LAWRENCE, Bart. A pretty dwarf species with umbels of ovate flowers forming an almost globular head. Cream-white tinged with rose. The plant bore six spikes.

NATIONAL AURICULA & PRIMULA.

APRIL 28.—"The Auricula in May has had its day" is a saying of the Lancashire florists, and certainly in the early years of the society's exhibitions it was safe to fix a date about April 20. The Auriculas were being staged on April 19, when the news was brought in of the death of the great Earl of Beaconsfield, but in recent years it would not be difficult to make a good show of Auriculas in May, and this year near the middle of May. The season has been most trying to the plants. The continued east winds have prevented the flowers from opening freely. An Auricula pip ought to open out flat, but this season they are frequently cupped and uneven. Some growers have tried placing the most difficult varieties, such as the green-edged Mrs. Henwood, in heat; this softens the corolla, but it causes the flowers to be smaller and weakens the foliage. In the green-edged section Mrs. Henwood was well shown, also Abbe Liszt, a very correct variety; Shirley Hibberd is one of the best in this class. In the grey-edged class there were few to equal the veteran George Lightbody, which was the premier show Auricula in the exhibition. This beautiful flower was raised by Mr. HEADLEY, of Stapleford, quite 60 years ago. Marmion is a very beautiful silvery, grey-edged variety, and was shown better than usual. The old Lancashire Hero was also to the fore, but it has fallen somewhat behind of late years. Olympus, a good grey, was also finely shown, and Richard Headley was also equal to the best of the modern flowers. In white edges, Acme has been rather disappointing; the flowers opened badly. Conservative was also in fair form. The plant is weakly in growth, but it usually gives a good flower truss. Heather Bell is a large flower with a violet ground colour, but, as usual, the florets showed too much of this shade. There were several new selfs, but amongst those in commerce Mrs. Phillips and Mikado, with dark maroon margins were the best. The variety Favourite, a new violet "self," is the finest in this class. In the class for a collection of 24 show varieties of Auriculas, Mr. JAMES DOUGLAS, Great Bookham, won the 1st prize with superbly-grown examples. Abbe Liszt, Mrs. Henwood and Shirley Hibberd were the best green-edged, Acme and Encharis the best whites, and George Lightbody, Olympus and Heather Bell the best greys. 2nd, Rev. F. B. HORNER, Kirkby Lonsdale, who exhibited some very good seedlings, as he has done for some years past. Shirley Hibberd was the best green in this collection. Artemis and Eurydice were the best "selfs." Azure, violet "self," was also very fine. 3rd, Mr. W. M. SHIPMAN.

In the class for twelve sorts, dissimilar, Mr DOUGLAS again won the 1st prize. He showed a fine new self of merit named Harrison Weir; George Lightbody was also very choice.

In the class for six distinct varieties J. T. BENNETT-POE, Esq., Holmwood, Cheshunt, took the 1st prize, his Miss Prim, white-edged, being a choice example. The same exhibitor won in the class for four distinct varieties.

In the class for seedlings MARTIN R. SMITH, Esq., Hayes, Kent (gr. Mr. C. Blick), secured the first honours with The Sirdar, a green-edged show variety of excellent form. WILLIAM SMITH, Esq., Bishop's Stortford, gained the 1st prize for a white-edged seedling with Stately—a handsome well-proportioned flower.

In the class for 24 Alpine Auriculas Mr. DOUGLAS was again to the fore, having Rosy Morn, Teviotdale, Argus, Martin Smith, Mrs. Markham, and Ettrick. Orion and Mars are very fine gold-centred varieties; these two, with Majestic and others, were exhibited in this class by Messrs. PHILLIPS & TAYLOR, Bracknell. For twelve Alpines Mr. DOUGLAS was again in the premier position. His Teviotdale is a striking white-centred variety, but Mrs. Douglas is a new seedling, superior to the former, and a flower of great promise. This variety was declared the premier bloom in the Alpine section. Mr. J. J. KEEN, Southampton, took the 1st prize in the class for six Alpines.

For six Alpine Auriculas (seedlings) Mr. MARTIN R. SMITH, Hayes, Kent (gr. Mr. C. Blick), was 1st, having good plants of Miss Audrey Campbell, Emperor, Ophelia, &c.

For twelve fancy kinds Mr. DOUGLAS and Mr. MARTIN SMITH took the 1st and the 2nd prizes respectively.

For a collection of Primulas, twelve kinds, Mr. MARTIN R. SMITH was 1st. The same exhibitor was 1st for a group of Primulas or Auriculas.

In the class for a collection of Polyanthus Mr. MORTIMER, Farnham, Surrey, was 1st, with plants of a fine strain. 2nd, Mr. J. CROOK, Camberley, Surrey.

MIDLAND DAFFODIL.

APRIL 23, 24.—Never in the history of the Midland Daffodil Society has any of its annual exhibitions been opened under worse climatic conditions than those which prevailed at Birmingham on the opening day. Snow and sleet commenced to fall about 8 a.m. on the 23rd ult., and continued without intermission until 8 p.m. The weather on the second day was better, but snow fell at intervals, and the sun shone only for a short time. Owing to the very cold late spring, the display was not so extensive as the one held a year ago, but the quality of the exhibits generally was excellent, especially the flowers staged by Mr. E. M. CROSFIELD, Mr. P. D. WILLIAMS, Mr. W. A. WATTS, Mr. C. DAWSON, Messrs. CARTWRIGHT & GOODWIN, and Messrs. BARR & SONS. A feature of the show was the great increase in the number of new varieties of Daffodils raised and staged by the exhibitors themselves; it is doubtful if so many really good seedlings have ever been seen at one time upon the exhibition tables of any society. The schedule consisted of between 50 and 60 classes, including several new ones, of which one was provided for new varieties, and another for seedlings. Two Silver Challenge Cups were offered this year for the first time, one as a permanent memorial to the late Rev. S. E. Bourne, who was associated with the Midland Daffodil Society from its inception, the other being given by Mr. R. C. Cartwright, of King's Norton.

Immediately following the formal opening of the exhibition by Her Grace the Dowager Duchess of Sutherland, the Rev. G. H. Engleheart, on behalf of a number of ladies and gentlemen, presented Mr. Robert Sydenham with a handsome illuminated album, and a massive solid silver candelabra to Mrs. Sydenham. Mr. Herbert Smith, one of the hon. secretaries, was the recipient of a silver tea service and a purse of gold.

In the evening Mr. Robert Sydenham entertained the principal exhibitors, judges, and visitors to dinner at the Grand Hotel. After the usual loyal toasts had been honoured, the rest of the evening was spent on Daffodil chat, prominence being given to the classification of the Daffodil.

CUT FLOWERS (OPEN CLASSES).

The leading class was for a collection of 50 varieties of Daffodils, representing the magni-coronati, medio-coronati, and parvi-coronati types. Four exhibits were placed before the judges, who awarded the 1st prize to E. M. CROSFIELD, Esq., Cossington, Bridgwater (gr. Mr. Tomlinson), for a wonderfully fine collection of shapely flowers, beautifully arranged. Last year's winner, F. H. CHAPMAN, Esq., Rye, was awarded the 2nd prize, and Messrs. CARTWRIGHT & GOODWIN, Blakebrook, Kidderminster, the 3rd.

The last-named exhibitors and Messrs. POPE & SONS, King's Norton, were the only competitors in the following six classes, and in each instance the 1st and 2nd prizes were awarded in the order in which their names are given:—(1) Nine distinct varieties of yellow self trumpet Daffodils (magni-coronati); (2) nine distinct varieties of bicolor trumpet Daffodils; (3) nine distinct varieties of medio-coronati Daffodils (chalice crowned), with yellow or sulphur perianths; (4) nine distinct varieties of medio-coronati Daffodils (chalice crowned), with white perianths; (5) 12 distinct varieties of parvi-coronati Daffodils (saucer or flat crowned), including Engleheartii type (poeticus varieties excluded); and (6) six vases of Polyanthus or Poetaz Narcissus, not less than four varieties. The flowers staged by Messrs. CARTWRIGHT & GOODWIN were uniformly good throughout, and included several varieties of outstanding merit.

In a class for six distinct varieties of the true poeticus type, F. H. CHAPMAN, Esq., beat Messrs. CARTWRIGHT & GOODWIN. The flowers in the 1st prize stand were of excellent quality, and were much admired. The varieties were: Almira, Barcarolle, Virgil, Homer, Dante, and Horace.

Messrs. CARTWRIGHT & GOODWIN were the only exhibitors in a class provided for six varieties of double Daffodils, in not fewer than four varieties.

AMATEUR CLASSES.

A class was provided for a collection of Daffodils in 25 varieties, the bulbs not to cost more than 10s. each. Of the five contestants, the Rev.

T. BUNCOMBE, Black Torrington, N. Devon, was awarded the 1st prize. His flowers were beautifully fresh, a few of the best varieties being: Madame Plemp, Gloria Mundi, Madame de Graaff, J. B. M. Camm, Almira, Cassandra, Leonie, and Barrii conspicuus. H. B. YOUNG, Esq., Metheringham, Lincoln, who was awarded the 2nd prize, staged some choice flowers.

A well-contested class was that for six distinct varieties of Daffodils, none of which were to cost more than 3s. per dozen. The first prize was gained by H. B. YOUNG, Esq., who had splendid flowers of Maximus, Emperor, Leedsii, Minnie Hume, John Bain, Sir Watkin, and Poeticus grandiflora præcox; 2nd, W. A. WATTS, Esq., St. Asaph.

Mr. YOUNG also took the lead in a class for six distinct varieties of yellow self trumpet Daffodils (magni-coronati), and the Rev. T. BUNCOMBE beat ten other competitors in the next class provided for six distinct varieties of bicolor trumpet Daffodils.

In the class for six distinct varieties of medio-coronati Daffodils (chalice crowned), having yellow or sulphur perianths, the 1st prize was awarded to Mrs. JOHNSTON, High Lea, Bideford, for a beautiful set of flowers; 2nd, W. A. WATTS, Esq.

Another class, similar to the above, but for flowers having white perianths, brought eight exhibitors. H. B. YOUNG, Esq., was placed 1st with uncommonly good flowers of the varieties Seagull, Duchess of Westminster, Minnie Hume, Katherine Spurrell, White Queen, and White Lady; 2nd, Rev. T. BUNCOMBE.

The best six varieties of parvi-coronati Daffodils, including Englehearti type, came from the last-named exhibitor, the Rev. G. P. HAYDON being 2nd.

W. A. WATTS, Esq., won the 1st prizes in the classes provided for (1) six varieties of true poeticus, (2) three distinct varieties of double Daffodils, and (3) three distinct varieties of Polyanthus Narcissus.

THE BOURNE MEMORIAL CHALLENGE CUP.

This exquisitely-designed cup, subscribed for as a memorial to the late Rev. S. E. Bourne, was offered in a class for 12 varieties of Daffodils raised by the exhibitor. The trophy was won by P. D. WILLIAMS, Esq., St. Keverne, Cornwall, who showed pretty flowers of the following varieties:—Charles I., Agrappince, White Wax (with lovely pale trumpet), Sheba, Augusta, Hestia, Claudia, Snowbird, Lavender, Hornet (a beautiful flower, with a pale lemon-coloured perianth and a very rich orange-coloured crown), Beeswing, and Quilp. The 2nd prize went to E. M. CROSFIELD, Esq., Cossington, Bridgwater, whose collection also contained many choice blooms. The varieties were as follow:—Elnair, Red Macaw, Frost Bound, Pixie, Faction, Satisfaction, Crystal, Lolah, Shell, Circular, Divinity, and Casilda. Eight exhibitors contested in this class.

There were seven exhibits in a class provided for three distinct varieties of magni-coronati seedling Daffodils not yet in commerce, and six exhibits in the next class for the same number of flowers, all of which the schedule required to be raised by the exhibitor. Mr. E. M. CROSFIELD won the 1st prize in both classes, and Mr. P. D. WILLIAMS the 2nd prizes.

In another class for three new varieties of parvi-coronati seedlings raised by the exhibitor, the awards were reversed, Mr. P. D. WILLIAMS being 1st with shapely flowers of Mikado, Julia, and Sunrise.

THE CARTWRIGHT CHALLENGE CUP.

This was presented to the Society by Mr. R. C. Cartwright, and was offered for 12 varieties of Daffodils which have not been in commerce for a longer period than four years. Although only three exhibits were staged in this new class, the flowers were surprisingly good. The 1st prize was won by Mr. E. M. CROSFIELD, who showed Malaga, Lolah, Tiara, Penguin, Athelta, Stay Sail, Mrs. Ernest Crosfield, Radiant, Giraffe, Phantasy (with delicate sulphur trumpet), Makeshift, and Potent (pale yellow trumpet); 2nd, Rev. G. P. HAYDON.

Mr. P. D. WILLIAMS secured the premier position in a class for six varieties of any Daffodils that have not been in commerce more than four years; 2nd, Messrs. CARTWRIGHT & GOODWIN; 3rd, Messrs. POPE & SON.

AWARDS TO NOVELTIES.

Narcissus Buttercup.—A medium-sized, deep self flower of the magni-coronati type. (First-Class Certificate.) Shown by Mr. C. DAWSON, Penzance.

N. Chloe.—This also belongs to the magni-coronati type. A beautifully-shaped flower, with a broad, cream-coloured perianth, and a soft, canary or pale yellow cup. (Award of Merit.) Shown by Mr. T. BATESON, Beaworthy, N. Devon.

Saxifraga Pitton Seedling.—A dainty plant, with deep crimson flowers, borne on stiff, wiry stems, nearly 5 inches high. (Award of Merit.) Shown by Messrs. BARR & SONS, Covent Garden, London.

Viola gracilis.—This plant is dwarf, compact, and bears a profusion of small, violet-blue flowers. (Award of Merit.) Shown by Messrs. R. WALLACE & CO., Colchester.

CUPS AND MEDALS.

Messrs. Barr & Sons' Silver Daffodil Vase, offered to the most successful amateur in certain classes, was won by Mr. W. A. WATTS, St. Asaph.

The Medals offered by the Birmingham Botanical and Horticultural Society were awarded as follow:—

The large Silver Medal, as champion prize in the open classes, was won by Messrs. CARTWRIGHT & GOODWIN, and the large Bronze Medal was won by Messrs. POPE & SONS.

The large Silver Medal offered to the most successful exhibitor in the amateur classes, was won by Mr. W. A. WATTS, and the Bronze Medal in the same classes to the Rev. T. BUNCOMBE.

The large Silver Medal offered in another section was awarded to Mr. A. CRYER, and the Bronze Medal to Mr. W. H. PARTON.

HONORARY EXHIBITS.

Daffodils were well shown, especially by Messrs. BARR & SONS, Covent Garden, who secured the only Gold Medal awarded; Miss CURRY, Lismore, Ireland (Silver-Gilt Medal); Mr. C. DAWSON, Penzance (Large Silver Medal); Mr. A. M. WILSON, Keal Manor, Spilsby (Small Silver Medal); Messrs. R. H. BATH, Wisbech (Small Silver Medal); Mrs. BACKHOUSE, Hereford (Small Silver Medal); Sir JOSSLYN GORE-BOOTH, Sligo, Ireland (Large Silver Medal); Rev. G. H. ENGLEHEART, Dinton (Vote of Thanks); Messrs. HOGG & ROBERTSON, Dublin (Large Silver Medal); and Messrs. R. WALLACE & CO., Colchester (Small Silver Medal).

Exhibits of other plants were contributed by Messrs. HEWITT & CO., Solihull (Large Silver Medal); Messrs. BAKERS, Codsall and Wolverhampton (Large Silver Medal); Mr. VINCENT SLADE, Taunton (Large Silver Medal); Messrs. GUNN & SONS, Olton (Silver-Gilt Medal); Messrs. SUTTON & SONS, Reading (Large Silver Medal); Mr. ROBERT SYDENHAM, Tenby Street, Birmingham (Small Silver Medal); Mr. S. MORTIMER, Farnham, Surrey (Large Silver Medal); the Misses HOPKINS, Mere Gardens, Shepperton (Small Silver Medal); and Mr. C. H. HERBERT, Acock's Green.

DEVON DAFFODIL AND SPRING FLOWER.

APRIL 21.—The exhibition of the above society, held in the Guildhall, Plymouth, on this date, was, notwithstanding the lateness of the season, the best held under its auspices. The entries, especially in the classes limited to residents in the county of Devon, were numerous, and the competition generally was exceedingly keen. Among the best of the exhibits were six pots of greenhouse Cyclamen exhibited by Mr. T. MARTIN, and half a dozen pots of Zonal Pelargoniums shown by Mrs. BAINBRIDGE. A 1st prize was awarded to both these exhibits. Another noteworthy exhibit was a collection of unnamed Daffodil seedlings shown by Mr. J. C. WILLIAMS in the non-competitive classes.

In the class for 30 varieties of Daffodils, the 1st prize was won by Mr. G. SOLTAU-SYMONS, Chaddlewood, Plympton, and the best collection of 12 varieties of Daffodils was shown by Mrs. W. TYACKE. The best nine varieties of Narcissi of the magni-coronati type were displayed by Miss C. VIVIAN, while in the corresponding class for nine varieties of flowers belonging to the medio-coronati section the 1st prize was won by Mrs. W. TYACKE. Miss VIVIAN showed the best three varieties of parvi-coronati Daffodils, and she was also the exhibitor of the best three varieties of blooms of the incomparabilis type, the best six Daffodils having orange-coloured crowns, the best single bloom of a parvi-coronati Daffodil, and the best six bunches of Anemones. Mrs. W. TYACKE was the winner of the silver cup offered by Messrs. Barr & Sons, King Street, Covent Garden, London, for the best group of Daffodils in the exhibition, and the same lady, in addition to those already stated, excelled in the class for three varieties of N. poeticus. Other prize winners in the classes for Daffodils were Mr. H. G. HAWKER and Miss M. WILLIAMS. Mr. HAWKER also showed the winning flowers in a class for six bunches of Anemone fulgens. The 1st prize for 12 varieties of hardy spring flowers was won by Mr. H. W. GRIGG, and he was adjudged the 1st prize winner in the class for six varieties of species of Tulips. Mr. J. C. WILLIAMS showed the finest Rhododendrons and Camellias, winning the 1st prize for a group of Rhododendrons, a truss of Rhododendron bloom, six plants of Camellias, and cut flowers of Camellia.

In the class for 15 varieties of hard-wooded flowering shrubs, the 1st prize was won by the Earl of MOUNT EDGCUMBE, who had a splendid exhibit, including amongst other subjects the rare Heterotoma lobelioides, Embothrium coccineum, Cestrum Newellii, Brachysema acuminata, Clianthus puniceus, Correa bicolor, and Acacia dealbata.

There were 40 classes provided for the residents of the County of Devon only, and most of the exhibits in these were of a high order of merit. A group of Daffodil seedlings shown in this section by Mr. T. BATSON contained many interesting flowers.

Among the non-competitive exhibits, Messrs. BARR & SONS, King Street, Covent Garden, London, displayed a collection of Daffodils of all types; the DEVON ROSARY, Torquay, exhibited pot Roses; and Mr. HAYWARD MATHIAS, Medstead, exhibited Carnations.

HUNTINGDONSHIRE DAFFODIL AND SPRING FLOWER.

APRIL 21.—The third annual exhibition of this society was held at Huntingdon on this date, and the show was again a success. Many fine non-competitive exhibits were staged by nursery firms who make a speciality of the Narcissus. The quality of the flowers in the amateur classes was, considering the unfavourable weather of the past season, very good. Lady LILFORD was the winner of the cup offered by Messrs. Barr & Son, King Street, Covent Garden, London, this making the second time she has won the trophy. Other prize-winners included H. R. DARLINGTON, Esq., Mrs. HOWELL USTICKE, Miss L. L. LINTON, and Lady DE RAMSEY.

THE WEATHER.

THE WEATHER IN WEST HERTS.

Week ending April 29.

Remarkably heavy falls of snow for April.—The last 10 days have been very cold both during the daytime and at night, but to-day it has been much warmer. During the 10 days referred to the temperature on the coldest day did not at any time rise above 40°, which is 16° colder than is seasonable, and on the coldest night the exposed thermometer showed 10° of frost. On one day during the past week the ground was 6° colder at 2 feet deep, and as much as 9° colder at 1 foot deep, than is seasonable. Rain, snow, or hail has fallen on all but one of the last 10 days, and to the aggregate depth of over 2½ inches, which is ¾ inch in excess of the average quantity for the whole month. At seven o'clock on the morning of the 24th the average depth of the snow on the ground was 6 inches. I can only say that during the previous 22 years I have never recorded in April a deeper covering than 1 inch, and that was quite early in the month. Had none of the snow melted on reaching the ground I calculate the ground would have been covered with 9 inches of snow on the following morning, instead of 6 inches. On the 25th snow lay for a time to the average depth of 1¾ inch, and on the 26th to the average depth of 2½ inches—both quite distinct falls from that measuring 6 inches on the 24th. That the ground is now thoroughly saturated is shown by the fact that virtually the whole of the melted snow and rain of the past week has already come through the 2½ feet of soil in the bare soil percolation gauge. The sun shone on an average for only 3½ hours a day, or for two hours a day short of its usual duration at this period of the year. Three days proved altogether sunless. Light airs again, as a rule, prevailed, the direction being very variable. The mean amount of moisture in the air at 3 o'clock in the afternoon exceeded a seasonable quantity for that hour by as much as 17 per cent. A swallow was first seen on the watercress beds at Berkhamsted on the 24th, or 16 days later than its average date in the previous 17 years, and later than in either of those years. *E. M., Berkhamsted, April 29, 1908.*

MARKETS.

COVENT GARDEN, April 29.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—ED.]

(*Continued on p. xii*).

ANSWERS TO CORRESPONDENTS.

CUCUMBERS FAILING: *T. D.* The unsatisfactory condition has been caused by too great an amount of moisture both at the roots and in the atmosphere, thus causing the leaves and the fruits to become charged with an excess of water. Apply water sparingly for a short time and afford as much ventilation to the house as is practicable.

HIPPEASTRUM INFLORESCENCE INJURED: *H. W.* The wound was caused in the first place by some mechanical injury, and when the epidermis or skin was broken a fungus disease gained an entrance.

NAMES OF PLANTS: *C. B.* 1, Saxifraga (Megasea) crassifolia; 2, Episcia fulgida, a plant requiring stove treatment.—*G. L. P.* Ercilla volubilis, a pretty evergreen, suitable for a wall.—*C. W.* Primula verticillata.—*E. W. S.* Dendrobium fimbriatum.—*J. M.* 1, Pteris tremula; 2, Euonymus latifolius variegatus; 3, Asphodelus luteus (Yellow Asphodel).—*Cantreyn.* 1, Dendrobium chrysotoxum; 2, Oxalis Bowiei; 3, Cerastium species.—*J. E.* 1, Begonia argyrostigma; 2, Begonia incarnata; 3, Begonia metallica; 4, Begonia fuchsioides; 5, Hibiscus Rosa sinensis; 6, Dracæna Godseffiana.—*E. C.* Cœlogyne cristata alba and Cypripedium politum.—*V. R. T.* 1, Masdevallia triaristella; 2, Pleurothallis Scapha; 3, Oncidium Iridum; 4, Epidendrum elongatum.—*O. H.* Dendrobium Dalhousianum. The plant you describe is a very fine example.

ODONTOGLOSSUM CRISPUM: *W. B.* The flower you send is one of Odontoglossum crispum, but your form would not be retained in a collection of the best varieties. For the best type of markings you should refer to the *Gardeners' Chronicle* for April 11, fig. 104, p. 239. The colours of the best-known varieties are chestnut brown, red-purple, crimson, rich chocolate, yellow, and various shades of rose.

PEACH SHOOT DISEASE: *A. E. E.* The disease affecting your Peach shoot is "Silver Leaf," for which no satisfactory remedy is known. Some authorities have recently stated that an application of lime to the soil has proved beneficial to trees affected with this complaint.

PRIVET HEDGE: *R. R.* Before your hardy annuals have had time to cover the bare stems of your Privet hedge the latter will have broken into leaf; we, therefore, do not advise your planting even temporarily any climber to hide the bare stems of the Privet.

SOIL IN VINE BORDER: *T. L.* The yellowish growth in the soil is "Flowers of Tan," a fungus that sometimes is said to cause injury to roots of plants. Dust the surface of the soil with a small amount of nitrate of potash, and afterwards give the borders a watering.

TWIN-SPATHED ARUM: *J. T. L.* Examples of double-spathed Richardias are frequently received from correspondents, and in some cases the second spathe is entirely devoid of green colouring. We do not regard the abnormality as any great advance on the ordinary plant, but it may be interesting to fix the same as a curiosity.

VINE SHOOTS AFFECTED: *J. S. L.* The branch has been injured from some cause, with the result that gumming has ensued. As the rod will not recover sufficiently to give further satisfactory results, it should be entirely removed and a new cane be trained in its place.

WARTS ON VINE LEAVES: *Nemo.* The pustules on the under-surfaces of your vine leaves are caused by intumescences, or undue development of the tissue, which may result from charging the atmosphere of the vinery with too much vapour and neglecting to maintain sufficient ventilation. If you correct these wrong cultural conditions the new foliage will soon assume the normal. There is no disease present in the leaves.

THE STATE AND HORTICULTURE.

ENGLAND has for many years possessed high ideals as regards the methods employed in garden culture, and the attainment of these ideals has been mainly the result of private enterprise. The time has arrived, however, when something more than individual effort should be brought to bear upon the development of one of the most important industries in this country. Whilst some few British horticulturists were recently enjoying the great floral feast at the Ghent exhibition, we at home learned that the Belgian Government had just instituted a Department in horticulture. Occasionally an opportunity presents itself of comparing the support afforded by our Government in such matters as horticulture with that provided by Continental nations, and so far we have no reason to be grateful for any support given us at home. A strenuous appeal would doubtless be needed to reach Parliament, but it ought to be made, for no one can say with truth that State recognition is not merited. The State can collect and distribute evidence of the utmost value to the gardener, and the gardener still has much to learn. Rough cultural methods are seldom afterwards practised when a person has discovered that he is more than compensated by the extra care devoted to the plants under his charge. Opinions emanating from a department having Government support, with the right men to furnish the information necessary to those requiring it, would be of the greatest help to thousands. Englishmen are sufficiently responsive, and if their attention is directed to any improvement or advance in cultivation that will be remunerative, they are certain to adopt it, for there is a strong imitative tendency among cultivators in acquiring new ideas that promise remunerative results.

A good deal has recently been said and written about the French system of early vegetable culture and the large profits to be made from it. The dung frame is a very old institution in this country, and has for years served a very useful purpose, and is still doing so, in places in which more up-to-date methods in the way of hot-water pipes have not been adopted. We cannot convert the whole of our gardens into solid masses of humus, nor is it necessary to do so; but every cultivator is aware of the value of hotbed manure, for when properly prepared and thoroughly decomposed, a few inches of such material near the surface soil is of the greatest value to quick-growing, succulent-leaved plants, and even the highly-selected forms of Carrots revel in it without attempting to make strong side roots.

The dwarf Erfurt-type of Cauliflower is another example of a vegetable that requires the richest cultivation possible to yield marketable heads early. In fact, all the small types of this vegetable are useless unless a quick growth is encouraged in rich soil. Personally, I know that there is money to be made out of early vegetable culture by those who understand this business. At the present time the land in England is greedy and poor, and a few thousand pounds sterling may soon be lost in the endeavour to improve a few acres of ground, if the principles underlying the working of it are not understood. This is one reason why I am convinced that it is a mistake to cry "back to the land" too loudly. If the small holdings, of which so much is heard, are to be a real success, they must be tenanted mostly by gardeners, and gardeners of the best type, who, by years of keen observation and applied methods, know how to reach their goal in the quickest possible time. There are now plenty of such men to be found, and the opportunity for gaining knowledge on horticultural subjects of a scientific nature is every year becoming more easy to obtain. We have often been told that there are scores of gardeners working on a scientific basis without knowing it. Has not the time arrived when such sayings should be robbed of a good deal of the meaning now applied to them? It may safely be stated that there are no classes of gardeners who would not greatly benefit by a careful perusal of the principles on which all work should be carried out. Some of us are asking for better conditions for the gardener, and we are hopeful that the time is not far distant when it will be recognised that the gardeners of England are worthy of a higher social status. The results achieved in our gardens, often under the direction of one man with thousands of subjects to deal with, are not ordinary but extraordinary. Young gardeners of the present day have excellent opportunities for making progress in their calling, but they must apply themselves studiously to all that pertains to the profession. They need to follow up their school life with more matured thought, and to teach themselves what to reject and what to imitate in others. Perhaps few gardeners believe statements that appear in the lay Press concerning the profits to be made from the cultivation of the land, but all the same we desire to see the establishment of a Government department of horticulture, whose officers would need not only to disseminate valuable information but also to refute statements that may indeed be based upon facts, but at the same time contain many details that are grossly misleading. *C. F.*

NOTES FROM THE "FRENCH" GARDEN.

The experienced manager of a "French" garden has to be largely guided in his work by the weather, for almost everything is based upon the climatic conditions to which the crops are subjected. During the past week the only work of importance has been the sheltering of the plants under lights.

The cutting winds, the dull weather during the day, and the frost at night time have had an ill-effect on all the crops. The tissues of the Melons have become hard, and the young shoots which should be green, thick, and healthy, are weak and thin; the female flowers which are now appearing will be useless, and we shall have to wait for others before choosing those for fruiting. Fortunately, we have kept the plants very dry at the roots, and if sunny weather sets in we shall look for more hopeful results.

We have prepared the ground for our first batch of Endive in the open, but, although the plants are ready, we await more favourable weather before shifting them into their final quarters.

Our first batch of Cos Lettuces is nearly all harvested. We have planted Cauliflowers in their place, on the two outside rows of each bed. We can already notice an improvement in the growth of the second batch. The satisfactory forcing of Cos Lettuces depends upon the plants being all at the same stage of growth, because the Lettuces must all be removed at one time, or it would be impossible to place the cloches on the second batch.

The paths are kept at the same level as the beds by filling them with well-decayed dung. This practice facilitates the removal of the cloches, and prevents them lapping over the paths on one side of the bed.

Throughout the recent heavy snowstorms and frosty weather we have ventilated both day and night the frames in which the Carrots and Cauliflowers are growing. These plants must be well hardened, for when the weather becomes more genial we shall remove the frames and lights entirely, and use them for the Melon crop.

We are growing a few plants of "Parisian Green" Cucumber this year.

We sow the seeds in the same manner as the Melons, and they receive the same care and attention as the latter during the first part of their growth. When grown on a large scale the seeds are sown from March 20 to April 20, and they are planted in their final quarters not later than May 25. *Paul Aquatias, Mayland, Essex.*

LOPEZIA LINEATA ZUCC.

THE genus Lopezia, belonging to the natural order Onagraceæ, includes rather more than a score of species. Some of these are well worthy of wider popularity than they seem at present to enjoy, for their highly-coloured pink or red flowers and stems form a pleasing addition to the conservatory in the early spring.

FIG. 131.—LOPEZIA LINEATA: FLOWERS PINK.

Two flowers, and the pollen (in the centre) are shown on a larger scale. From specimens supplied by Messrs. James Veitch & Sons, Chelsea.

The flowers are interesting, owing to their irregular or zygomorphic character, and they exhibit remarkable structural features which are adapted to secure cross-pollination. Three of the four sepals are turned towards the posterior part of the flower, whilst the fourth lies medianly forward. The corolla consists of four petals, all of which tend to lie somewhat posteriorly in the flower. Two of the petals (antero-lateral ones) are brightly coloured and are obovate with a long claw. Those of the postero-lateral pair have undergone a remarkable modification, each being abruptly bent backwards at about 1-16th inch from the base, and one or two thickened cushions or pustules of tissue, more or less green in colour, are situated just at the place of bending at X X. (fig. 131). These pustules resemble nectaries, but as a matter of fact the real nectaries are at the base of the petals, and the pustules are in no way glandular, nor do they secrete a sugary liquid. They are perhaps comparable in this respect with the false nectaries of Parnassia.

The stamens are two in number, but only the posterior one is fertile, the other (St[e] in the figure), which lies immediately over the anterior sepal, being converted into a petal-like staminode. In some of the species the anther of the fertile stamen is gripped in the folded terminal part of the staminode, and is liberated with a jerk when an insect touches the filament. The two organs then spring apart, the staminode lying prone over the sepal, whilst the anther is moved over to the posterior side of the flower. This curious mechanism is found in L. coronata, but not in all the other species, although the stamen and staminode are constantly present.

Self-pollination is prevented in these flowers because the stigma does not become mature, nor, indeed, does the style elongate fully, till long after the dehiscence of the anther.

The usually globose, inferior ovary is four-chambered, as in so many of the Onagraceæ, and the carpels are opposite the petals.

The best-known species in cultivation is probably L. lineata (1). This plant was described by Zuccarini (2) from a specimen grown in the Botanic Garden at Munich, but the Royal Horticultural Society appears to have introduced it into this country through seeds which were sent by Mr. Hartweg from Mexico.

Lopezia lineata seems to be often confounded with another species described by De Candolle (3) in 1813 under the name of L. mineata. The latter plant, however, differs in at least one important character from L. lineata, as is shown in a series of elaborate drawings by Jacquin (4). The postero-lateral petals bear two glands in place of the single one of L. lineata, and there is also a downward prolongation of the limb of each of the two petals on either side of the pair of pustules. It has been possible to confirm this by reference to an authentic specimen of L. mineata in the Herbarium of the Natural History Museum. A further point of difference between the two species has been based on the hairy character of typical L. lineata, as contrasted with the (alleged) glabrous L. mineata, This character, however, breaks down in practice, for the latter species is not really glabrous, but shows lines of hairs running downwards from the bases of the leaves exactly like those of almost glabrous specimens of L. lineata. Probably cultivation may be responsible for the reduction of the hairs of the latter species, for wild specimens show a considerable range of variation, from nearly glabrous to pilose or almost shaggy stems.

The comparison of a number of specimens preserved in the Herbaria of Kew and the Natural History Museum leads to the conclusion that L. lineata, mineata, mexicana, and some others constitute a group of related forms, which somewhat closely resemble each other in general appearance. But the single pustule, and the absence of the downwardly-projecting spurs or horns from the right and left of the postero-lateral petals, close to the false nectaries, seem sufficient to distinguish L. lineata from L. mineata, with which it is so often confused. *J. B. F.*

SOME ANNUAL COMPOSITES.

USEFULNESS is the hall-mark which characterises the natural order Compositæ. The flowers, on the whole, do not partake of the ephemeral nature of the Papaveraceæ, nor do they ever attain to the fragrance which gives to some of the prominent representatives of the Leguminosæ their popularity.

The natural order Compositæ is well represented in gardens by species of annual duration, and these are of inestimable value for beautifying beds and borders during the summer months.

It is in supplying flowers for the adornment of the home that the annual Composites

are justly esteemed; they last well, and most of the species provide colours acceptable either in daytime or by artificial light.

Zinnias some years ago enjoyed a measure of popularity greater than they do at the present time. They are a splendid type, yielding rich, deep shades of colour, the flowers being compressed within a form which approximates to the florist's ideal. Zinnias, when well grown, are admirable subjects for furnishing flower beds and they are not infrequently employed in the more formal part of the garden. Unquestionably, the double Zinnia is superior to the single form. A beautiful Californian Composite is Cosmos bipinnata, which is a replica in miniature of a Dahlia flower, though the plant itself attains to a greater height. The flowers are produced in autumn, and are borne freely by plants growing in rather poor soil in a sunny position. It is here that reference may fittingly be made to those bright bedding Composites which are comprehensively grouped under the name of China Asters, and are varieties of Callistephus sinensis. These are alike useful for large or small gardens; they produce effective masses of colour, and are valuable for certain classes of decorative work. Although the double China Asters are the most popular, the type itself produces single flowers, and is becoming in greater request each year, as the flowering season extends well into the autumn.

The best forms of annual Helianthus are varieties of H. cucumerifolius, which produces small flowers, and H. annua, which produces very large flowers. The predominant colour throughout the genus is yellow, there being a lemon-coloured form in both sections, which contrasts well with the dark central disc. Species of Helianthus are best grown in rather poor soil, and under such conditions the flowers are produced in the utmost freedom. The Marigold section includes Calendula and Tagetes, and among these are found many plants with bright flowers, the plants being useful alike for the shrubbery margin, bed or border, and never averse to rich soil, though the flowers, as a rule, come freest in one of a medium richness.

Annual Chrysanthemums have received two notable additions recently, named respectively "Morning" and "Evening Star." They are forms of Chrysanthemum tricolor, of which it may be said that all are good garden plants, though to ensure the maximum beauty allowance must be made when planting for free lateral development. When so treated, there is almost no end to the flowers they can supply; the colours are rich, and have a large range of shades, and the blooms last well in water. To the same good purpose Calliopsis Drummondii and C. nigra speciosa adapt themselves; the flowers of the latter are of a shade of maroon which appears almost luminous under artificial light. C. Drummondii is particularly impatient of overcrowding, and when cramped the rich yellow flowers suffer in size with a corresponding weakness in the stem.

There is one fine group of these annuals which deserves special mention. I refer to the beautiful new Centaureas distributed by Messrs. Jarman & Sons, of Chard. The plants grow freely under liberal treatment, and the flowers are produced on long stems. The range of colours is restricted, though the shades are very pure, qualities that are essential in all arrangements calling for lightness and delicacy of colouring.

There is a beautiful little annual called the Swan River Daisy (Brachycome iberidifolia), which simply covers itself during summer and autumn with small flowers resembling Cinerarias. I consider the blue-flowered form to be the best. It is a tender annual, and is best raised in a cold frame and planted out in tufts. I have found it to succeed beyond expectation when employed to carpet the bare ground among shrubs.

Throughout these notes I have spoken of true annuals which require sowing during April or May. A brief reference may be made to Humea elegans, a biennial which is justly appreciated for its elegant drooping inflorescence flowered in the open garden, or, as is frequently the case, in pots. Seed must be sown about mid-summer and the plants grown in pots in a warm house through the winter to ensure suitable specimens for the garden the following year. *Thomas Smith, Walmsgate Gardens, Louth, Lincs.*

PLANT NOTES.

IRIS TINGITANA.

A NOTE by Herr Novik in *Moller's Deutsche Gartner-Zeitung* draws attention to the beauty of the flowers of this species of Iris, and the uses of the plant when grown under glass. In the open ground, the plant, though hardy enough to withstand a northern climate, is injured in its flowers by the dry, harsh winds of early spring. In the warmer parts of this country, if planted in sheltered positions, the flowers might not suffer in this respect. Herr Novik states in his interesting note that on the Riviera the plant flowers in the month of January, that is, two months in advance of Iris hispanica. The flower-shafts reach a height of 2½ to 3 feet. The flowers resemble those of the blue Iris hispanica, but they are twice their size. The great length of time the unopened flower-buds last in good condition, if cut before they expand, renders this species excellent for cut flowers for the market; as likewise the fact that the second bloom following that which has expanded and passed, develops perfectly, like those of I. hispanica. Cut flowers placed in water remain for two to three weeks in good condition.

The late Professor Michael Foster was the first to introduce I. tingitana to the Riviera, he having sent some rhizomes to a friend residing probably at Hyeres. The plant is readily propagated, and it will doubtless soon become cheap. It is a native of northern Morocco, and takes its name from a little town near Tangiers. *E. M.*

FLOWER BEDS AT BROUGHTON CASTLE.

IN our issue for March 7 a description was published, with several illustrations, of the gardens attached to this old residence. Fig. 132 shows an artistic design in flower beds on the lawn to the west of the castle, and bounded by the moat. This flower garden is enclosed by dwarf hedges of Yew, with wide openings at intervals. There are also a number of isolated plants of this tree clipped in a formal manner and terminating in figures of birds. The central bed is planted with Golden Yews, which are clipped in a globular form, and these are kept very dwarf over a groundwork of the common Mahonia (Berberis). The four round beds were planted last summer with Pelargonium Paul Crampel, and they were edged with Cerastium tomentosum having as a central object a clump of Galtonia (Hyacinthus) candicans. There are eight outer beds, and these are planted with hardy herbaceous plants and sown with annuals. Each of these beds is furnished alike to present a uniform colour effect. They are gay with flowers from the last week in May until the end of October.

FIG. 132.—FLOWER BEDS ON THE LAWN AT BROUGHTON CASTLE, OXON, AS PHOTOGRAPHED FROM THE ROOF OF THE CASTLE.

NOTICES OF BOOKS.

* "HEREDITY."

PROFESSOR J. A. THOMSON has already acquired a well-deserved reputation as an exponent of biological theory, and his new work on heredity will be cordially appreciated by all students of scientific natural history. From the nature of the case, it can hardly be termed a popular book, for the subject is one which can neither be understood nor profitably discussed

* By J. Arthur Thomson, M.A., Regius Professor of Natural History in the University of Aberdeen. London: John Murray, 1908. 9s. net.

except by those who have had some biological training. To all serious students of botany and zoology, however, and especially to those who interest themselves scientifically in problems of plant and animal breeding, the work should prove of great value.

The subject is treated in a strictly impartial manner. The principal theories of heredity which have been put forward at various times are briefly discussed, and special attention is devoted to the views of Lamarck, Darwin, Galton, Herbert Spencer, Weismann, Mendel, and De Vries. The inevitable question as to the inheritance or non-inheritance of acquired characters is fairly discussed, and we observe that, though the author's own views seem to incline towards the negative answer, as given by Weismann, he does not omit to refer to the Neo-Lamarckian opinion that altered conditions of life, *if continued long enough*, may possibly have a cumulative effect, which is capable of stamping itself permanently upon the organism and becoming transmissible by inheritance. This also appears to be a general opinion amongst practical breeders, though the author considers that the evidence given by breeders in support of the theory of "modification-inheritance" is, in most cases, too full of vagueness and misunderstanding to be of significance. As to the mechanism by which the transmission of "acquired characters" may be supposed to be effected, we have Darwin's theory of "Pangenesis," and Herbert Spencer's hypothesis of "Physiological Units," but we note with special satisfaction the following quotation from Sir Ray Lankester: "In fact, in place of the theory of emission from the constituent cells of an organism of material gemmules which circulate through the system and affect every living cell, and accumulate in sperm-cells and germ-cells, we may substitute the theory of transmission of force, the two theories standing to one another in the same relation as the emission and undulatory theories of light." Professor Thomson considers that in biology we are not yet in a position to utilise ideas of "modified force-centres," or "transmission of force," but we have long felt that this is a direction in which we may hope for real progress.

Perhaps the most important advance which has been made in recent years in the study of heredity lies in the increase of our knowledge regarding what is known as Mendelian inheritance. This subject is one of intense interest to horticulturists, for it is one which any intelligent gardener can follow up for himself. The importance of the experiments lies in the fact that they afford some hope of an ultimate analysis of each organism into a number of "unit-characters," which may be independently transmitted to the offspring; but it still remains to be seen how far this idea of unit-characters is applicable. Mendel experimented with the common edible Pea, by crossing varieties which exhibit constant differentiating characters, such as round and wrinkled seeds. He found that in the first (hybrid) generation one of the two contrasted characters was "dominant" and the other "recessive." All the offspring of the cross *apparently* belonged to the dominant type; but when these offspring were allowed to fertilise themselves, he found in the next generation that the contrasted characters separated out again in the proportion of three dominants to one recessive. This shows that the hybrid dominants of the first generation are "impure." Further experiment shows that the "extracted" recessives of the second generation are pure, and will never again yield dominants, while two-thirds of the dominants of this generation are again impure and one-third pure. The impure dominants, when again allowed to fertilise themselves, behave like the impure dominants of the first generation, and yield the same definite proportions of dominant and recessive offspring, viz., 1D + 2D(R) (= impure dominant) + 1R. From this it is concluded that the germ-cells of the organism, the egg-cells and sperm-cells, each contain only one of the pair of contrasted characters, while the offspring produced by the union of germ-cell and sperm-cell may contain either or both, according to the apparently quite fortuitous combination of the germ-cells. The proportions in which the offsprings are produced should therefore follow the law of chance, and this is exactly what takes place in the case under discussion. Many cases of such simple Mendelian inheritance are now known, but it is by no means certain that the law is of universal application, and it usually appears to be complicated by so many obscure factors as to be unrecognisable in the present state of our knowledge.

The experimental results of Mendel and his followers may at first sight appear not to harmonise with the statistical results obtained by Galton, according to which "the two parents between them contribute *on the average* one-half of each inherited faculty, each of them contributing one-quarter of it. The four grandparents contribute between them one-quarter, or each of them one-sixteenth; and so on" to infinity; but, as Professor Thomson says, "It is simply muddle-headedness which can find any opposition between a statistical formula applicable to averages of successive generations breeding freely, and a physiological formula applicable to particular sets of cases where parents with contrasted dominant and recessive characters are crossed and their hybrid offspring are inbred."

FIG. 133.—FLOWERING SHOOTS OF PRUNUS TOMENTOSA FROM GLASNEVIN.

The author also deals—though all too briefly, we fear—with the very important results obtained during recent years in the study of the microscopic structure of cells, and the changes in the nucleus which accompany ordinary cell-division, and the maturation and union of the germ-cells. Important evidence as to the actual existence in the germ-cells of material particles, which may be looked upon as the bearers of the transmissible characters, is afforded by such study. Other matters dealt with are the experimental study of the processes of fertilisation and development, which have lately yielded truly marvellous results, and the mutation theory of De Vries; while a final chapter deals in an extremely interesting manner with the social aspects of the problem of heredity.

The author has endeavoured to cover an immense field, and, in spite of the somewhat unwieldly size of the book, the treatment of the subject is necessarily much condensed—we regret the more a considerable amount of repetition, which, with more careful arrangement, could have been avoided. Not the least valuable feature of the work is a selected bibliography, which should save the student much trouble in his further studies. As a matter of mere human curiosity, we should like to know the reason for the introduction of the solitary "tail"-piece at the end of Chapter VI. It is certainly a good tail-piece, but why should this chapter alone be thus favoured? *A. D.*

* Les Pois de Senteur.

English authors who write in the French language on horticultural subjects are few and far between, but Mr. G. D. Clark, nurseryman, at Dover, is an exception to the rule. He has recently published a pamphlet on the Sweet Pea bearing the above title. The work consists of 32 pages, in which is given the history and culture of this popular flower for the benefit of growers on the other side of the Channel. There are nine short chapters covering such subjects as the improvement of the Sweet Pea, culture in the open, in tubs, in the greenhouse, dwarf Sweet Peas, and a list of varieties. Several illustrations are given. Mr. Clark is a member of the National Horticultural Society of France, and has exhibited Sweet Peas at several French exhibitions.

† How to Raise Daffodils from Seed.

This work is a useful little manual of about 60 pages that deals with the flower's early history, the first garden seedling, Miller on seed raising, Daffodils in the 17th century, Dean Herbert, Edward Leeds, Horsefield, Wm. Backhouse, Rev. G. H. Engleheart and their work, and then proceeds with an account of seedling raising in the various sections. It is a useful and interesting brochure for the Daffodil amateur.

‡ "Mother Earth: A Proposal for the Permanent Reconstruction of our Country Life."

Mr. Fordham has written a readable and, in many respects, a suggestive book. He has endeavoured to deal with the causes of depletion of the rural population, and to suggest remedies for a condition of things that every true friend of the highest national interests must constantly deplore. But, whilst it is not very difficult to describe the proximate cause of, and the evils that result from, the exodus from rural England of the best of the men and women who form the backbone of the nation, it seems to surpass the wit of man to find a really satisfactory

* By G. D. Clark.

cure. Mr. Fordham suggests a series of remedies, which many will regard as Utopian, and others will dismiss as little short of pure Socialism. He is fully conscious that the root of the evil lies in economic conditions, but it is very doubtful if his ideas as to a Government Department, entrusted with the management of a big co-operative business, could possibly prove a success. For such a Department, in order to be effective, would have to become a monopolist, and this would unquestionably arouse intense hostility in a body of people much too large to be safely ignored. The suggestions as to fixing land values, of giving the right of access to national capital, and many other similar proposals, may possibly constitute a "comprehensive scheme," but whether any such scheme is likely to prove workable in practice will probably appear very doubtful to the majority. Perhaps the first point to settle is whether the people at large are prepared to pay a special price to assure the cultivator of the soil a favourable market, no matter what the conditions of external competition may be.

Anyone who reads Mr. Fordham's book, with its somewhat ambitious title, will find the issues fairly plainly put, and for this reason alone it is worth a perusal. Whether it will carry conviction or not will probably depend largely on the particular bias of the individual reader.

Fig. 134.—Fruiting spray of Prunus tomentosa from Glasnevin.

"CLUB-FOOT" DISEASE.

Many gardeners confound the work of the Cabbage maggot with diseases which affect the root, and have no connection whatever with insect injury. This is noticeably true of a form of disease which frequently affects the roots of Cabbages, Turnips, Broccoli, Cauliflowers, Mustard, Rape, and, among flowers, of Stocks, Candytuft, and allied plants, causing wilting and death of the plants.

On pulling up young Cabbage plants for transplanting, the roots are frequently found to be deformed by the development of nodular excrescences of all shapes and sizes, from those of a Pea to those of a fairly large, irregular, warty Turnip. Such plants are useless, for they develop no "hearts" or "heads" for market, for all the food that would normally have gone to make new leaves and flowers is diverted into the deformed roots, making them hard and stringy, when the gardener wishes them to be soft and succulent, as in the case of Turnips. After a time these malformed roots pass into a condition of decay and the plants wither and die.

In the vast majority of cases it is found that all this disaster results from the ravages of a very remarkable organism, allied to the fungi, and called "Club-foot," or Plasmodiophora Brassicæ, a name which refers to the slime-like character of the pest.

The growing plants are attacked at all ages, but it is especially young seedlings which suffer. The first indication of the plants being affected will be their wilting during warm days and their failure to recover at night.

The vitality of the disease spores is such that manure from cows or pigs fed upon clubbed roots will be found to affect allied plants grown on land where the manure is used. Such spores, it is proved, will live for two or three years in the soil. Manure, therefore, is one of the means of infection. Soil, it is claimed, transferred from one infected piece of ground to another will carry the spores, and thus infect other soils. Seed beds are frequently a great source of "club-foot."

Rotation of Cabbage and allied crops with some other, not of the cruciferous family; care in choice of manure; the keeping down of wild Mustard and other weeds of the same kind; sowing seed of Cabbages, Broccoli, &c., in new, uncontaminated soil; discarding seedling plants whose roots show the least indication of clubbing; and avoiding the infection of new ground by the transference of soil or refuse from infested areas, are all suggested as preventive or remedial measures.

Soils subject to this disease will always be found to be more or less acid, and a broadcasting of air-slacked lime, about 75 bushels to the acre, or 14 lbs. per square pole of ground has given satisfaction. During the winter season one ton of gaslime per acre may be trenched in. I have had evidence of excellent results from this practice.

On soils subject to the "Club-foot" disease it is advisable not to use low-grade superphosphates, as these always contain a certain amount of free acid, which favours the development of the spores.

Basic slag and bone meal may be recommended in quantities varying from 4 to 6 cwts. per acre, or 2¾ to 4 lbs. per pole.

On discovery of the "Club-foot," the whole of the diseased plants should be pulled up and immediately burned, and the ground treated with lime or basic slag. *J. J. Willis, Harpenden.*

PRUNUS TOMENTOSA.

Of the earlier flowering species of Prunus, one of the rarest and least known in gardens is P. tomentosa. It is a spreading, comparatively low shrub belonging to the Apricot (or armeniaca section of the genus, and is a native of North China, and possibly of Japan. There is a fine specimen at Kew, 10 feet through and 6 feet high, just now laden with many thousands of flowers—a most beautiful object. The flowers are white, tinged with rose, each one ¾ inch or so across. The leaves (which do not appear until after the flowers are over) are oblong with a cuspidate apex, 2 inches long, and densely covered with a close, fine down. I saw a fine bush in the collection at Les Barrés a few years ago, and M. Maurice de Vilmorin gives a very characteristic portrait of it in his *Fruticetum*. In this collection there is also an interesting Prunus nearly allied to P. tomentosa but distinct, and probably a hybrid with the better-known P. triloba. The only defect of P. tomentosa as a shrub for the garden is that its flowers are somewhat fragile, and are liable to be damaged by the beating showers so common to the latter part of March and early April. But there is much to be said in favour of so beautiful a shrub which comes into bloom before the Almond. Its fruits are red, and about the size of small Cherries; they are so sparsely produced, however, that they do not count among the attractions of the species in this country. *W. J. B.* [At figs. 133 and 134 we illustrate the flowers and fruits of this species from specimens kindly sent us by Mr. F. W. Moore, Royal Botanic Gardens, Glasnevin, and sketched by Mr. Worthington Smith.—Ed.]

THE ALPINE GARDEN.

ERITRICHIUM NANUM.

The Alpine and Arctic floras admittedly contain no choicer gem than Eritrichium nanum, whose little tufts of small leaves form a pleasing setting to the exquisite azure-blue flowers, which are so beautiful that all who see them desire to possess the plant.

Notwithstanding the best of culture, the Eritrichium will not survive our seasons for long; its life in our climate is but a short one, and in most cases the first winter brings it to an untimely end. Even those persons who have tried to grow it in gardens in its native countries confess that it is one of the most difficult Alpines to preserve in cultivation, so it is scarcely surprising that in this country it should prove a troublesome subject. It is not a plant to be put in a good position on the rockery and left alone. Even where special care is taken it is not to be relied upon, and should be raised annually from seeds—the only method by which it can be propagated. I have seen it in several gardens, but all the plants were young, and some had been wintered under glass, while my own experience, and that of many whom I have consulted, is that, beautiful as it is, it is hardly worth considering as a garden Alpine. The great difficulty in this country is to keep it as dry at the roots in winter as it requires, and any cultural methods which do not take this into account are sure to end in disappointment. Even during its growing season, the foliage must not be damped, and from the beginning of September until early in February the plant must be kept at rest if possible, although it usually

begins to show growth at the end of January. The position afforded it must be such that the rain which falls is led to the roots of the plant without wetting the leaves. The best means of attaining this is as follows:—Place a stone or a sheet of glass over the plant in such a position as to shield it from rain but not from the sun, whilst allowing the moisture to reach the roots. From the end of August a stone or piece of glass must be so fixed overhead that the rain is turned from the roots also. The changes of our climate are so rapid and so extreme that even this care often fails in effecting the preservation of the plant, and the consequent disappointment is very great.

One is led to write these notes, as there are some persons who are tempted to purchase this truly exquisite plant, but who have not the least idea of how difficult it is to grow. They may well pause, and consider whether they will not be wiser to secure some Alpine plant more easily cultivated. The experience of generations of Alpine growers with Eritrichium is practically the same, and the little gem may therefore be looked upon as an Alpine flower for the few, and not for the many. *S. Arnott, Sunnymead, Dumfries.*

The Week's Work.

FRUITS UNDER GLASS.

By T. COOMBER, Gardener to LORD LLANGATTOCK, The Hendre, Monmouthshire.

The orchard house.—Pot trees, whose fruits are now swelling, should be top-dressed with well-decomposed stable manure and loam in equal parts. The pots being filled with roots close attention must be given to watering, for if the soil is allowed to become dry, especially in the case of trees bearing stone fruits, the latter will be liable to drop. Liquid manure should be occasionally given as a stimulant; it is best made by placing soot together with deer or sheep's manure in bags, and submerging them in a tank of water. This liquid manure must be freely diluted with water before it is applied to the plants. A moderately moist atmosphere should be maintained in the orchard house at this stage, and this can be provided by damping the floor and other bare surfaces in the house. In addition, the trees should be syringed daily, except during wet weather. The ventilation of the house should be in accordance with the external conditions, but it must be remembered that Apples, Pears, Plums, Apricots, and Cherries are all benefited by plenty of ventilation, including a certain amount during the night-time. The thinning of the fruits must not be hastened, though where there are very heavy crops a few may be removed early, in order that the tree may not be unduly exhausted. Attention must be given to the stopping and thinning of the shoots, and vaporising must be practised in order to keep down attacks of aphis.

Strawberries.—These plants will now require constant attention in order that the fruits may develop perfectly, but this will be greatly lessened if suitable houses for their culture are available. In these gardens a hip-roofed house, having an eastern aspect, is used for Strawberry forcing, the pots being placed on turves upon shelves suspended from the roof. The plants are not exposed to the full rays of the sun, which considerably lessens the work of watering, and red spider is not very troublesome. In addition, the fruits swell and ripen gradually, and they develop colour better than when the plants are fully exposed to the direct sunshine. On no account allow the plants to suffer from lack of water at their roots; also do not neglect to provide a stimulant in the form of liquid manure. Select a few of the most perfect berries for ripening, and remove the remainder, also any runners as they form. Ventilate the house freely whenever the weather permits, and on fine days syringe the plants freely in order to keep down attacks of red spider. The wetting of the foliage by the syringe and the application of liquid manure must be discontinued when the fruit commences to show colour. Should any of these forced plants be required for planting out, select those that were forced last, as these will give better results than those that were subjected to heat earlier in the season.

Bananas.—As soon as the young plants are sufficiently rooted, they should be planted in their permanent quarters, whether in tubs or in borders. The rooting medium should consist of rough loam that is enriched with manure or leaf-soil. Established plants should be kept actively growing, affording them an atmospheric temperature of 70 degrees at night-time, with a corresponding warmth during the day. Close the structure early on fine days, and syringe the plants freely, also damp all available places about them, and furnish copious supplies of water at the roots, occasionally enriching the water with liquid manure. Rich top-dressings should also be applied, for the Banana is a gross feeder. As soon as the fruits are formed, expose the bunches to the light, by drawing aside any leaves that obstruct the sun's rays.

PLANTS UNDER GLASS.

By THOMAS LUNT, Gardener to A. STIRLING, Esq., Keir, Perthshire, N.B.

Cinerarias.—Seeds of the various types of this plant should now be sown, in order to obtain plants for flowering early next season. The seed pans should be well provided with crocks for drainage, and on this should be placed a layer of rough soil, filling the remainder with a mixture of loam, leaf-soil, and sand, that has been passed through a fine sieve. Make the surface soil of the seed pan smooth, and then dip the pan half-way into a tank of water, so that the moisture will travel up the soil and thoroughly wet the whole. This is a better plan than watering with a rose, for the surface of the soil is not disturbed, as the moisture runs up by capillarity. The seeds should be sown thinly and evenly, and be covered with a thin layer of fine soil, in which has been placed some leaf-mould. Place a piece of glass over the seed pan, and shade the surface from bright sunshine. Maintain a moist atmosphere and a warmth of about 50° to 55°.

Schizanthus.—Seeds of this floriferous subject should now be sown for producing a batch of plants to flower in the early autumn. The same methods of seed sowing should be adopted as is recommended for Cinerarias.

Caladiums and Gloxinias.—The earliest plants should now be examined with a view to shifting them into larger pots should they require increased root room. These subjects should never be allowed to become potbound during their season of active growth, for if they receive a check at this stage the effects will be apparent all the season. See that the plants are not crowded on the stage, otherwise they will become drawn and develop an undesirable form.

Ferns that were not re-potted this spring and that are now growing freely should be given doses of weak liquid manure about twice a week. As the young fronds develop, the older ones should be placed towards the outside of the plants. Great care must be exercised when doing this, otherwise the young tender leaves will be damaged. Strict attention must be given to the matters of ventilating and shading, for these are essential points in the culture of Ferns as specimen plants. Place an abundance of moisture about all parts of the house, but prevent water falling on the hot water pipes, if the latter are very hot.

Stove plants that were not re-potted should be assisted by either artificial or liquid manures. In the case of coloured foliage and flowering plants, I prefer to use artificial manure, and for those with green leaves, liquid manure. When feeding plants, always err on the side of an under-dose rather than one that is too strong. Artificial manure may be distributed more easily and safely if it be first mixed with its own quantity of sand. It should be ascertained before applying these concentrated plant foods that the pot is well filled with roots, and that they can make use of the extra nourishment.

Freesias.—When these have finished flowering they should be allowed to complete their growth, and to perfect their bulbs, and, for purposes of ripening, they should be placed in a house having a sunny aspect and a cool temperature. When the leaves begin to die down, water should be withheld and the pots be placed on their sides until autumn, when the plants should be shaken out of the old soil and re-potted, selecting the largest bulbs for the purpose.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree, Hertfordshire.

Cauliflowers.—Plants which are growing in large pots in cool houses or pits, for providing an early supply will now be forming their curds, and should receive manurial assistance in the form of liquid manure given at alternate waterings. The leaves should be tied up to exclude the light immediately the heads are visible. For the purpose of prolonging the supply of this vegetable, some of the plants may be plunged at the foot of a south wall or fence, but they must be given some protection during severe weather. Should these Cauliflowers develop faster than they are required, some of them may be cut and be placed in a cool store, where they will last in a good condition for at least a fortnight. Successional batches of this vegetable growing in cold frames should be mulched with rich, half-decayed farmyard manure, and the roots be well supplied with an abundance of moisture. Afford plenty of fresh air to the plants, both by night and by day, and as soon as it is safe to do so remove the lights entirely. Spring-sown plants of such varieties as Magnum Bonum, Early Giant, Mammoth, and Autumn Giant which have been transplanted, and properly hardened, should be planted in their permanent quarters, the ground having previously been well prepared. Make them very firm in the soil and allow them ample room both between the plants and between the rows; in the case of strong-growing varieties, 30 inches between the plants in the rows, and the latter 3 feet apart will be found suitable. Make one more small sowing of Early Giant and Autumn Giant, as these varieties will, provided they are lifted during November and placed in cold frames, furnish a supply of small heads of good quality up till mid-winter.

Vegetable Marrow.—Early plants of this vegetable, whether planted on mild hot beds or in pots in an intermediate house for training up the roof, should now be in bearing. The growths should be thinned and regulated, much in the same manner as those of Cucumbers, and in order to ensure a good crop the flowers should be pollinated by hand. Diluted manure water should be given when the fruits are swelling. A final sowing of this vegetable should be made, placing the seeds singly in small pots; these will furnish plants for cultivation in the open. Seeds of Gourds and Pumpkins, including both edible and ornamental varieties, should be sown in a similar manner Many of the larger Pumpkins are excellent for the table when they are well cultivated and properly ripened.

Ridge Cucumbers.—Seeds of these should be sown now and germinated in heat The seedlings when properly hardened will be ready for planting in the open in a sunny and sheltered position by the end of the month. Ridge Cucumbers when properly grown are of equal and sometimes superior flavour to those cultivated under glass. The chief requirements of Ridge Cucumbers are plenty of moisture at the roots and conditions that promote a clean and free growth.

Capsicums and Chillies should now be given their final potting using either 5-inch or 6-inch pots, for preference the former size, as these are more useful for placing in jardinières and other fancy receptacles used for the purpose in dwelling-rooms. Place the plants near to the glass and maintain an average atmospheric temperature of 60°.

Beetroot.—The main and final sowing of this crop should now be made. When roots of special quality are required, it is often necessary to first bore holes with a crowbar or some other implement, and to fill these with a rich finely-sifted compost. The common sparrow frequently does much damage to the young seedlings of Beetroot as soon as they appear above the surface of the ground.

THE FLOWER GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

Bamboos.—The present is a suitable time for planting these ornamental subjects. A thorough preparation of the soil is of the utmost importance before the work is undertaken, and the ground should be stirred to a depth of not less than 2 feet 6 inches to 3 feet, and be enriched with farmyard manure. Single specimens should be afforded an abundance of root room. Before planting the more tender species they should be gradually hardened, and their final quarters should be chosen in a warm sheltered part, such as is provided on the borders of a woodland. Bamboos are moisture-loving subjects, especially during the summer months, and they succeed by the margins of a lake or a stream. Some of the more tender species are very graceful as pot plants, and a few should be reserved for this purpose. The propagation of the hardy varieties and species including B. Metake, B. aurea, B. Fortunei, B. nigra, and B. Simonsii, is easily effected by division of the old plants. A portion of the plant should be detached just as the new growths are appearing, and this should be planted in well-prepared ground, after which a copious watering should be afforded to settle the soil about the roots. Bamboos are often objected to on account of their dying after flowering, but I have not experienced much trouble in this respect, B. Simonsii being the only one I have lost from this cause, and this plant had been established for more than 30 years before it flowered. It is interesting to record that all the stock propagated from this same plant by division flowered at the same time as the parent, and all died together. Another interesting feature was that plants of the B. Simonsii flowered generally throughout the country concurrently with mine.

Flower bedding.—Spring-flowering subjects such as Wallflowers, Forget-me-Nots (Myosotis), Polyanthuses, &c., are very free-rooting subjects, and they soon exhaust the soil in which they are growing. Therefore, it will be necessary, before the summer occupants are placed into the beds, to provide some fresh food materials in the shape of leaf-soil and horse-droppings in the proportion of three-parts of the former to one of the latter. The whole should be well-mixed and freely dusted with soot. This dressing should be well incorporated with the soil, in order to ensure an even growth of the plants. When digging flower-beds and borders it is well, if manure is added, to turn the soil twice in order that the former may be evenly distributed.

THE HARDY FRUIT GARDEN.

By F. JORDAN, Gardener to The DOWAGER LADY NUNBURNHOLME, Warter Priory, Yorkshire.

Strawberries.—In the earliest districts these plants will soon be showing their flower trusses; no time, therefore, should be lost in applying the annual mulching of strawy litter from the stables. Thoroughly cover the soil with this material, and allow some of the longest to lie loosely around the plants to afford protection from frost. There are two advantages to be obtained from applying the mulch early, namely, the stained litter gets thoroughly washed before the fruit ripens, and should a long period of drought occur there will be less evaporation of moisture from the soil. If extra fine fruits are required for any special purpose, thin out the weakest flower trusses before the blooms open, and afterwards thin out the fruits when they are properly set. Plants that were forced having been carefully cleaned and hardened off for planting as recommended in the Calendar for April 11 should be planted out as soon as possible so that they may become thoroughly established before dry weather sets in.

Figs.—If the growths upon Fig trees appear numerous and weak they should be freely thinned out. The cold summer of last year was not favourable to the cultivation of Figs out-of-doors, and it may be found that there are unmatured unfruitful shoots that may be removed to make room for younger shoots nearer the centre of the tree. Do not treat fruitless trees with any liquid manure or mulchings, a drier root-run being more conducive to the growth of short-jointed wood that will ripen properly. The chief point in Fig culture out-of-doors is to keep the roots near the surface, and the growths thinly disposed, otherwise the wood will not ripen satisfactorily. The shoots on Fig trees against walls should never be pinched, as growths from the second breaks cannot ripen before bad weather sets in.

Loganberries and Blackberries.—In northern districts where room can be spared in cold houses, the Loganberry is well worth a place, the fruits being valuable for use in the kitchen at a time when other fruits are scarce. The plants are now developing numerous suckers from the base, and only the strongest of these should be laid in for fruiting next season, all the weak ones being removed. The same remarks apply to the plants growing outside, and to the Blackberries and Wineberries. No more shoots should be allowed to remain than are required for fruiting next season.

General work.—See that all grafts are made secure as recommended in a previous Calendar, and that the ground is kept free from suckers and weeds. Continue to train on and disbud young trees as it becomes necessary, and again attend to the watering of recently-planted trees against south walls.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Major G. L. HOLFORD, C.V.O., C.I.E., Westonbirt, Gloucestershire.

Lycastes.—Plants of L. Skinneri and its varieties, L. macrophylla, and the hybrid L. × Balliæ, have commenced their season's growth, and will need more water at their roots than hitherto. When the new shoots have advanced about 3 inches, the condition of the roots should be ascertained, and any plants requiring it should be re-potted. These plants should be grown in well-drained pots, because they require a plentiful supply of water during the summer months both at their roots and overhead. As a rooting medium, use equal parts of good, brown, fibrous peat, turfy loam, and chopped sphagnum moss, mixing the whole with a good sprinkling of coarse silver sand and broken crocks. Pot firmly, and place the base of the plants a little below the rim of the pot. The species L. aromatica, L. cruenta, and L. Deppei produce their flower-buds and new growths simultaneously at this season; therefore, the re-potting of these plants should be deferred until after their flowers have faded. L. Harrisoniæ is an old but very desirable Orchid when well cultivated, the plants producing their fragrant flowers at this season. After the blooms are past, and when new growths start from the base of the plants, fresh rooting material should, if necessary, be afforded. At Westonbirt this species succeeds in a basket suspended from the roof, and the plants are afforded more warmth than the other species named, these being accommodated in the cool intermediate house, where they are shaded from strong sunshine.

Anguloas.—A. Clowesii and A. Ruckeri are beautiful species known by the popular name of the cradle Orchid. These plants produce their flowers during late spring and early summer, the buds and new growths appearing together. After flowering, these plants should be examined, and if any are in need of re-potting, employ a similar compost to that advised above for Lycastes, but afford them rather more rooting space as they are strong in growth. The plants should be afforded a light position in the intermediate house, and be watered sparingly at first, but afterwards a plentiful supply of moisture may be given until the growth of the pseudo-bulbs is complete. These plants and Lycastes are subject to attacks of red spider, which infests the lower sides of the leaves. If the syringe is freely used on bright days, and an occasional spraying with some weak insecticide given, there will be little trouble with these pests.

PUBLIC PARKS AND GARDENS.

By JAMES WHITTON, Superintendent of the Parks and Open Spaces in the City of Glasgow.

Management of the ground used for games (continued from p. 270).—The proper maintenance of parts of the grounds which are devoted to games is an important part of park work. Daily attention to them is, in all cases, necessary during the playing season, rolling and mowing being a part of the daily routine. Parts of the park that have been altered and re-turfed during the autumn and winter months should have no games played thereon until the turf is in a satisfactory condition and the grass is growing vigorously. To give way to a clamour for the opening of any playground before the turf is in thorough order is a weakness too frequently exhibited by Committees of Open Spaces; but the Superintendent should resist as strongly as possible, and point out that a couple of months' delay in opening the ground may ensure two months' longer use before it becomes torn and worn, apart from the extra cost which will be entailed in putting it again in order. Any little pleasure afforded by the early opening is more than counterbalanced by the unsatisfactory condition of the turf in a short time. When once the turf is damaged the cause is often forgotten, and the Superintendent may be subjected to criticism and be blamed for bad management. It is assumed that all playgrounds were examined and treated according to their requirements at the end of last season's play. Should it be found, however, that parts are not so satisfactory as desired, a timely top-dressing of some light manure will materially assist matters. Lawns which have been treated regularly with some special manure—as most golf and bowling greens are—often appear sickly, due, in all probability, to an absence of lime. A slight dressing of freshly-slaked lime, which has been screened through a sieve having a ¼-inch mesh, and mixed with twice its bulk of sand to facilitate the spreading, will, as a rule, act as a corrective, especially if it is applied when new growth is starting. If a stimulant is required, there is nothing better at this season than a slight dressing of sulphate of ammonia. A safe quantity to use is about half an ounce per square yard, and it is better to apply a slight dose on two occasions than one heavy one. The sulphate may be mixed with sand in the same proportion as that for lime, to facilitate even distribution. It must not, however, be mixed and allowed to lie in bulk, as the salt readily diliquesces. It should be mixed and applied as soon as purchased. Bowling greens which were prepared last autumn will require extra attention until the roots of the grasses have spread through the adjoining turves. When mowing, dispense with the collecting box, and allow the cut grass to act as a mulch, which will tend to obviate cracking if the turves have been taken from a clayey soil. Use the roller judiciously. It is a mistaken idea that a bowling green cannot be too much rolled. The nature of the turf and the condition of the weather should regulate not only the use, but also the weight of the roller.

THE APIARY.

By CHLORIS.

Feeding.—To ensure success this year it will be necessary to maintain a supply of food for the increasing brood, and also to prevent the bees from leaving the hives during inclement weather. Should snow again fall, place a board in front of the flight hole to prevent the reflected light from the snow causing the bees to imagine that because there is a bright glare therefore the air conditions warrant their taking a flight.

Swarming.—Though few hives will be strong enough to swarm for some time, yet it is well to be prepared. Should it be desired to increase the number of hives, fit up the frames with wax foundation and have all things in readiness, so that when the bees swarm all will be in readiness. Bees are prepared for comb building when they swarm, and thus it is not necessary to fit up frames with full sheets of foundation; further, they generally build worker comb only during the first year after swarming, therefore all that is needed will be a "starter" strip of comb about an inch deep. If sections are placed above the queen—excluding zinc, the bees, having no storing space in the brood chamber, will be compelled to store in this most desirable portion of the hive, and thus, beside saving wax foundation by this method, a great quantity of excellent honey is obtainable in a very short period.

Bees deserting their hive.—Frequently bees desert a hive, as soon as they have apparently settled in their new home. There are several causes for this. The hives may be draughty, and if so the cure is apparent; the position may be too exposed; or the hive may be unclean. But for no apparent reason, as far as the most careful and thoughtful apiarist can determine, they will sometimes forsake their new home. It is well known that bees will not desert brood, therefore a comb of hatching brood placed in the centre of the new hive, will, provided the conditions otherwise are favourable, prevent them leaving.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, MAY 11—
United Hort. Ben. and Prov. Soc. Com. meet.

TUESDAY, MAY 12—
Roy. Hort. Soc. Coms. meet. Roy. Gardeners' Orphan Fund Coming-of-Age Festival at the Hotel Cecil, Strand. Nat. Rose Soc. Com. meet. Brit. Gard. Assoc. Ex. Council meet.

SATURDAY, MAY 16—German Gard. Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—52.3°.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, May 6* (6 P.M.) Max. 60°; Min. 52°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, May 7* (10 A.M.): Bar. 29·8; Temp. 58°; Weather—Fair, with sunshine.
PROVINCES.—*Wednesday, May 6* (6 P.M.): Max. 57° Colchester; Min. 50° Ireland N.

SALES FOR THE ENSUING WEEK.

WEDNESDAY—
Lilies, Herbaceous Plants, Hardy Bulbs, &c., at 12; Palms, Bay Conifers, Ferns, &c., at 3, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

WEDNESDAY, THURSDAY AND FRIDAY—
Unreserved Clearance Sale of the "Elmwood" collection of Orchids, at Elmwood Park, Hill Road, Croydon, by order of J. Wilson Potter, Esq., by Protheroe & Morris, at 12.

Wax Palms and Gramophones.

The importance of the great natural order Palmaceæ from an economic point of view is sufficient in itself, without any consideration of the habits or natural beauty of the plants, to justify the term often applied to them of "Princes of the Vegetable Kingdom."

Though the uses, to which some part or other of nearly every one of the numerous species is put, are so varied, it may safely, we think, be said, that the most valuable, from a commercial aspect, are the Cocoanut (Cocos nucifera) and the Palmyra (Borassus flabellifer). Perhaps, however, amongst the most interesting, and at the same time the least known, are those species which have the habit of excreting wax, either on their leaves or stems, such, for instance, as the Carnauba Palm of Brazil (Copernicia cerifera) and the so-called Wax Palm of New Grenada (Ceroxylon andicola). The first of these is one of the finest Palms of the Brazilian forests. The cylindrical stem rises to a height of 40 feet, and measures about 1 foot in diameter at the base. The leaf-stalks are about 6 feet long, and as the leaves die and wither they fall away, leaving the woody bases, still attached to the trunk, arranged spirally for some distance down. It is on the underside of the leaves that the wax is deposited, and it is collected either by gathering the leaves and exposing them in a dry place to wither, when the wax cracks or peels off in flakes, which is further assisted by shaking, or by scraping the wax from the leaves. In either case the wax is melted by heat and poured into moulds. Another mode of collecting it is by cutting the leaves into pieces and boiling them in cauldrons of water; the liquefied wax rises to the surface, and is skimmed off. As the leaves are exhausted of the excretion they are removed and other leaves are added. The wax so obtained is still in an impure state, but it is afterwards re-melted, and after the impurities have been removed, the wax is run into moulds where it hardens, and indeed becomes quite brittle.

When first introduced to this country, about 60 years ago, it was used for mixing with bees'-wax, for which purpose it is well adapted, both on account of its yellow colour and its hardness, the bees'-wax itself being of a very soft nature. It was also used in the making of candles, for which purpose, however, it did not meet with much favour, owing to the difficulties experienced at that time in bleaching it. The annual imports did not then exceed five or six hundredweights. Of late years there has been an increasing demand for this wax, and in a recent report on the subject it is said that in the States of Pernambuco, Ceara, and Bahia, its collection has become an important industry, and according to the trade returns the quantity exported varies considerably from year to year, but in round numbers amounts to 2,000 tons, of the value of £200,000. The increase in the exports and value of this wax, we are informed, is largely due to its use in making phonograph and gramaphone records, and though it is also used in making boot-polishes, the demand is chiefly in connection with the gramophone trade.

Ceroxylon andicola, the Wax Palm of New Grenada, differs from that just described, inasmuch as the wax is deposited on the trunk and not on the leaves. The tree grows to a good height, and the trunk is usually swollen about half-way up, contracting again towards the top. The scars of the petioles of the long pinnate leaves are very distinctly marked all over the trunk, and between each scar is a deposit of wax, often so thick that it can be removed in flakes. This wax forms an article of trade in New Grenada, and is used by the people for making candles. The average yield of one tree is said to be about 25 lbs. The Kew museums contain some excellent specimens both of the trunks and leaves of these Palms as well as of the different kinds of wax.

OUR SUPPLEMENTARY ILLUSTRATION affords a view of the garden front at Compton Place, Eastbourne, showing the flower beds and borders in their full beauty in summer time. On the occasion of the death of the late Duke of DEVONSHIRE, we were enabled to publish a full-page illustration (see issue for March 28, p. 203, of another part of these gardens, and we then stated that Compton House was a favourite residence of his Grace, and that this residence was the scene of much entertaining on the part of the late Duke and the Duchess. Most of the towns on the south coast of England are particularly favoured in their situation, and as they enjoy in winter a very mild climate they are visited by many invalids during convalescence. None is, perhaps, more favoured in this respect than Eastbourne, and in summer time a holiday there is even more enjoyable, for then such beautiful homes as Compton Place are surrounded by flowers that not only adorn the beds and borders, but ramble up the sides of the residence and hang in festoons from window boxes and vases.

ROYAL HORTICULTURAL SOCIETY.—The next meeting will be held in the Society's Hall, Vincent Square, Westminster, on Tuesday, May 12, at 3 o'clock. A lecture on "Gardening in the West Highlands" will be delivered by Mr. O. H. MACKENZIE.

ROYAL GARDENERS' ORPHAN FUND.—We desire again to remind our readers that the coming-of-age festival dinner of the Royal Gardeners' Orphan Fund will take place on Tuesday next, at the Hotel Cecil, at half-past six for seven o'clock p.m. The president of the fund, the Duke of BEDFORD, K.G., will preside. Our readers are asked to assist in making this event as successful as possible.

HORTICULTURAL CLUB.—We are informed that owing to the annual dinner of the Royal Gardeners' Orphan Fund being held on Tuesday, the 12th inst., and to the first day of the Temple Show being on Tuesday, the 26th inst., no house dinner will take place during May. Dinner will be served at the club, at 6.30 p.m., on Tuesday, May 26, for those members who may wish to dine together after the show.

THE "GEO. MONRO CONCERT COMMITTEE."—We are given the following details of the proceeds at the last annual concert, which was held in the Queen's Hall on February 23. Donations have been given to the following institutions:—Gardeners' Royal Benevolent Institution, £15 15s.; Wholesale Fruit and Potato Trades' Society, £10 10s.; Charing Cross Hospital (Covent Garden Committee), £5 5s.; Surgical Aid Society, £6 6s.; Royal Westminster Ophthalmic Hospital, £3 3s.; Covent Garden Lifeboat Fund, £3 3s.; The Geo. Monro, Ltd., Pension Fund £4 4s. (and outing fund), £3 3s. A balance of about £10 will be added to the reserve fund.

NATIONAL TULIP SOCIETY.—The fifteenth annual exhibition of the southern section of this society will be held on Tuesday, May 26, in the Royal Horticultural Hall, Vincent Square, Westminster. The secretary is Mr. W. PEETERS, Farcet House, Cambridge.

FRANCO-BRITISH EXHIBITION AT SHEPHERD'S BUSH.—The management of this exhibition have arranged for a show of plants and flowers to be held on May 19 and 20 next. The schedule provides for 21 classes, several of which are open to both French and English exhibitors; there are others for amateurs only, and several are open to all comers. The prizes include gold, silver-gilt and silver medals, and in almost every case a money prize will accompany the medal. Gold and silver medals for miscellaneous exhibits not specified in the schedule will be awarded at the discretion of the judges. Diplomas or certificates will be awarded to meritorious novelties, such awards to be open to exhibitors of both nations. All particulars may be obtained from Mr. J. A. ALEXANDER, the superintendent of horticultural shows, Franco-British Exhibition, Shepherd's Bush. Intending exhibitors must give eight days' clear notice to the superintendent of their intention to exhibit.

Flowers in Season.—Blooms of a very fine double Daffodil known as Primrose Phœnix have been sent us by the raiser, Mr. John Walker, Thame, Oxon. The colour is a soft primrose yellow. Not the least valuable quality of the flower is its form, which is of the rosette type, but extremely regular, with the petals well developed.

Kew Guild Annual Dinner.—The annual dinner of the Kew Guild will take place on Monday, May 25, at the Holborn Restaurant. Mr. William Pettigrew, Superintendent of Parks, Cardiff, will preside. A number of Colonial and Indian members will be present, including Messrs. G. Cave (Darjeeling), E. W. Davy (Nyassaland), R. Derry (Singapore), A. E. Evans (Gold Coast), and G. T. Lane (Calcutta).

The Perpetual Flowering Carnation.—Messrs. Hugh Low & Co. inform us that, as last year, they will be pleased to present a free copy of a work on Carnations to all horticultural and gardening societies who apply for same.

Hippeastrum "Purity."—This plant was awarded a First-Class Certificate at the meeting of the Royal Horticultural Society on the 28th ult., not an Award of Merit, as stated in our report.

The Royal Academy.—The 140th exhibition of the Royal Academy opened on Monday, May 3. The chief honours will probably go to Mr. F. Brangwyn, A.R.A., and Mr. J. S. Sargent, R.A. The former shows a very fine decorative picture entitled "The Return," gorgeous in colouring and masterly in execution; the latter several notable portraits, the finest, perhaps, being "H.R.H. The Duchess of Connaught," although the splendid full-length portrait of "The Right Hon. A. J. Balfour, M.P.," will no doubt run it very close in public favour. Mr. H. H. La Thangue, A.R.A., sends several delightful pictures, No. 282, "Ligurian Flowers," being particularly happy in its strong sunlight effect. Mr. Alfred Parsons, A.R.A., has a large landscape, a valley, with old Hawthorn bushes, Gorse, and Bluebells, all in full flower. The watercolour room contains several very pretty drawings of gardens, Mr. A. Parsons' "The Rose Garden, Poulton Briary," Miss M. Nixon's "The Herbaceous Borders, Drakelowe," "The Wild Rose Tangle," by Woodbine Hinchliff, "Summer," by Miss A. Bauerle, will all make us long for summer to be here. One of the pictures that will attract most attention is a very large canvas by Sir Hubert von Herkomer, R.A., "The Council of the Royal Academy, 1907," a cleverly-arranged group, rather coarsely painted, but full of life. Mr. Tuke's "Midsummer Morning," No. 197, should on no account be missed; and Mr. J. J. Shannon's "The Infant Bacchus," and his portrait of "H.R.H. Princess Patricia of Connaught," are very worthy specimens of this painter's delightful work.

The Nursery and Seed Trade Association, Limited.—The annual general meeting of this association was held at the offices, 32, Gresham Street, London, E.C., on April 27. Mr. G. Bunyard (Messrs. Bunyard & Co., Ltd., Maidstone) presided, and there were also present the following members: Mr. Arthur W. Paul (Messrs. William Paul & Son), Mr. William Bull (Messrs. Bull & Sons), Mr. G. H. Barr (Messrs. Barr & Sons), Mr. H. W. Nutting (Messrs. Nutting & Sons), Mr. A. E. Protheroe (Messrs. Protheroe & Morris), Mr. B. B. Maller (Messrs. B. Maller & Son), Mr. A. E. Silberrad (Messrs. R. Silberrad & Son), and Mr. C. W. Nieuwerf (the Harrow Nursery Co.). The report of the committee submitted to the meeting showed that the financial position of the association was improving yearly; the amount standing to the credit of the association on December 31 last was £169 7s. 4d., consisting of £121 5s. 10d. at the bank and outstanding subscriptions, commission, and status enquiry fees amounting to £48 1s. 6d., part of which has since been paid. The members present at the meeting stated that the association had been of great service to the trade, as it had during last year answered 870 status enquiries and had collected accounts amounting to £5,515 11s., principally in small sums, after the members had done all in their power to obtain payment by letters. The association had expended £19 3s. 8d. in making special enquiries relative to persons seeking credit. Mr. N. N. Sherwood (of Messrs. Hurst & Son) was re-elected president of the association; Mr. W. J. Nutting was re-elected treasurer, and Mr. G. H. Barr and Mr. H. Simpson (Messrs. Cooper, Taber & Co., Ltd.) were re-elected trustees.

A New Privet.—Prof. E. Heinricher some years ago discovered a plant of Ligustrum vulgare growing near Innsbruck that bore deep, creamy-yellow flowers. He found that cuttings, when they flowered, retained the peculiarity, as was, indeed, to be expected. He has succeeded in raising young plants from seed, and finds that they come true as regards the floral characters. Prof. Heinricher considers the plant of horticultural value, and designates it as Ligustrum vulgare mutatio flore lutescente. This rather cumbrous name might perhaps be conveniently replaced by L. vulgare var. lutescens.

Publications Received.—*The Vegetable Growers' Guide*, by John Wright, V.M.H., and Horace J. Wright, with 30 coloured plates and upwards of 200 diagrammatic drawings illustrative of practical points. Vol. 1 (London: Virtue & Co., 7, City Row, City Road).—*The Royal Gardens, Kew* (illustrated), by E. J. Wallis and H. M. Spooner. Price 1s.—*Dahlias and their Cultivation*, by J. B. Wroe. Published at the *Amateur Gardening* Office, 148 and 149, Aldersgate Street, E.C.—*Studies in Fossil Botany*, by D. H. Scott, F.R.S., Vol. 1 (second edition). Published by Adam and Charles Black. Price 6s.

CONTINENTAL NOVELTIES.

ACACIA BAILEYANA.

A beautiful species of "Mimosa" Acacia is mentioned in *Möller's Deutsche Gartner-Zeitung* for March 21, which is equally good for producing cut bloom in the open on the Riviera as for pot culture in more northern climates. This fine species was obtained some years ago from California, and it succeeds in light soils on its own roots on the Riviera, whilst in the heavier loamy soils of the San Remo district it must be grafted on A. floribunda. The foliage is very pleasing, it being twice feathered, and of a silvery-blue tint that harmonises splendidly with the pendant golden-yellow risps of flowers. At San Remo, Paul Brauer, the writer of the note accompanying the figure of the plant, states that the plant begins to flower in the middle of the month of November, and continues in bloom till the beginning of February, at which time A. dealbata is in full bloom. The flowering shoots of A. Baileyana bear carriage well and fetch good prices, varying from 3 to 5 francs per kilo. As a market plant for the Christmas season, at which period the flowers are at their best, it is sure to find favour with the public.

TRIDAX BICOLOR ROSEA.

As a suitable annual for affording cut blooms, Tridax bicolor rosea may be warmly recommended. The plant, unfortunately, is but little known in gardens, although it possesses handsome flowers, which surmount tall stalks and are of a clear, distinct pink colour not found in many other species of plants. In regard to soil the plant is not particular. It should be raised in the same manner as Asters, Phloxes, Salpiglossis, and the like. The flowers are suitable for furnishing vases, &c. The plant is not injured by 2° to 3° of frost.

BEGONIA HYBRIDA ELSMERI.

In this fine winter-flowering plant we have a highly decorative subject for the warm greenhouse and winter garden, and one that commences to produce its flowers in October and continues to do so till March. The growth is vigorous and candelabra-like in form, and produces numerous flower stalks carrying fresh-coloured stellate blooms of a large size. The only fault that can be urged against it is the readiness with which the heavy blooms fall off the succulent stalks when carelessly handled. As a market plant, except when quite young, and before it flowers, it is for this reason not to be recommended. An admirable illustration of a specimen plant in full bloom is given at p. 244 of *Die Gartenwelt* for February 22. *F.*

THE FERNERY.

PLATYCERIUMS (STAG'S-HORN FERNS).

The genus Platycerium is represented in gardens by relatively few species, although many that are not generally cultivated possess good features that render them useful decorative objects in the Fern-house. The best-known species is P. alcicorne, from which, by sporting, P. a. var. Hillii was derived. Both are excellent Ferns for use in dwelling-rooms. In former times it was generally believed that Platyceriums were difficult of culture and that their growth was slow and unsatisfactory, but these opinions, as a better knowledge of the requirements of the plants have shown, are groundless. If the plants can be accommodated in a glass-house by themselves, the cultural conditions can be better adapted to their needs than when they are included in a mixed collection of stove plants.

The propagation of Platyceriums in general is difficult and slow when it has to be carried out by means of offsets, a method of reproduction which cannot be adopted in the case of all species of Platyceriums. P. grande, for example, develops no offsets, and it was one reason why this species was formerly so little grown in gardens. But as soon as the possibility of the propagation of Ferns by means of spores became known, it was easy to raise this particular species in thousands. When Ferns are raised from spores, they may differ in several desirable points from their parents; moreover, the young plants are actually new plants, with individual characteristics, and do not represent, as in the case of divisions, merely vegetative succession. Herr Fieb, of the Botanic Garden, Groningen, published his method of increasing Platyceriums in a communication in the *Revue Horticole*, p. 209, for 1899. This method succeeding, the experiment has since been repeated by him with other genera and with good results.

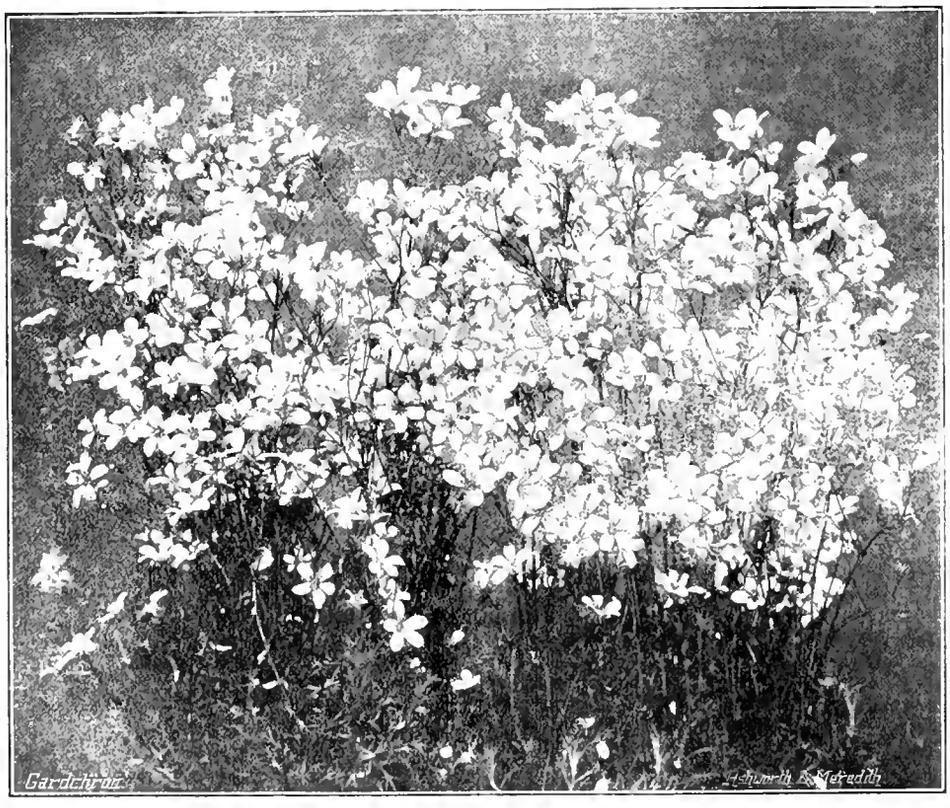
Platyceriums are epiphytal on trees in the tropics, and they are near allies of the genus Acrostichum, of which they form a sub-family. They possess two forms of fronds, the normal and the so-called Nischen or nest, the barren fronds. The latter bear no spores, but in the space between the barren frond and the stem of the tree there accumulates a collection of dead leaves and a variety of other vegetable substances, and this débris furnishes the plant with nutriment. The barren frond is thickened at the base, and furnished with strong veins or ribs, whilst the lamina is thin above, sometimes branching and expanding, so as to

catch the refuse and hold it fast. At the base of the barren fronds are found the roots of the plant. The fronds are less intended to serve the purpose of assimilation than the collecting of this humus and moisture, functions that they exercise, even when they are dead. Not every normal frond is fertile, the spore-bearing leaves appearing only when the plant has reached a certain age, and provided the conditions of life are favourable. Both forms of fronds are similar in appearance when young, and in a young plant the fertile fronds may be missing entirely. The normal fronds often possess a rachis, and they are finally shed by the plant, which is not the case with the barren fronds. On both forms of leaves there is a felt-like covering of stellate hairs, which indicate that the plants in their natural habitat enjoy a moist atmosphere, but they must not be subjected to heavy syringings, for these would spoil the felty covering of the plant.

The spores are formed in masses on the first or second branchings, or at the tips of the fronds, and on their under surface.

need the highest degree of warmth, and even in the resting period the warmth must not be much below the normal.

Tree stems have been mentioned as the objects to which these Ferns are attached in their habitat, but they readily cling to cork slabs, soft sandstone, and porous brick and tiles; P. Hillii makes a capital room plant when grown in a flower pot. The best kind of soil for the culture of Platyceriums is a mixture of the fibrous parts of loam, charcoal, cow dung collected from the pastures when dry, and sphagnum-moss; light kinds of turf should be soaked in cow-dung water. In the spring, when growth begins, a quantity of this soil should be inserted behind the old barren frond or shield, under which the roots by upheaval can be seen. Behind the very young barren fronds no roots will be found, and no soil must be introduced behind them or they will be decayed and the plant injured. Many gardeners imagine that epiphytal plants need no sort of solid food, but if this is withheld, the growth is checked and the plant presents a generally miserable appearance.



[Photograph by Chas. Jones.

Fig. 135.—Saxifraga hypnoides: flowers white with faint pink dots.

Some botanists have described 13 species of Platycerium, but most of these are regarded by other authorities as garden forms or varieties. Experience has shown that very frequently one and the same mass of spores will afford varied forms of plants; for example, spores of P. Willinckii, obtained from the Marburg Botanic Garden by the authorities of the Botanic Garden at Groningen in January, 1899, produced a batch of plants in which were two individuals which differed from the rest, in the form, branching, and habit of the fronds.

Warmth and moist air are the chief cultural requirements of these Ferns, and, as stated above, not much syringing must be given, as this ruins the felted covering of the fronds. Water must be afforded sparingly at the roots in the winter, this being the resting period of the plants. It may here be remarked that P. alcicorne is content with less warmth than any other species. P. angolense and P. æthiopicum need the highest degree of warmth, and even in the resting period the warmth must not be much below the normal.

When applying water to Platyceriums, it should be poured behind the barren fronds, where the roots are to be found. *M.*

SAXIFRAGA HYPNOIDES.

The accompanying illustration (fig. 135) shows one of the mossy Saxifragas, S. hypnoides, a section well known to the gardener by reason of the free-growing nature of the plants, the dense carpet of foliage produced, and the myriads of blossoms that almost hide the foliage during the early summer months. For the surfacing of beds as "carpet" plants for edgings, for cool or moist positions in the rock garden, and for many another position in the garden where a free-growing plant of the easiest culture is desired, a selection of these mossy Saxifragas invariably gives satisfaction. For the most part the species and varieties included under the head of "mossy" are of an evergreen character, the exceptions being such usually deciduous kinds as S. Maweana, S. gibraltarica, &c. Not infrequently this deciduous character is not recognised, and the tufts are as a result discarded. This is unfortunate, as the first-named is one of the finest white-flowered species in the group, and it is also interesting as being one of the parents of the handsome and popular S. × Camposii, which is also known as S. Wallacei. The species forming the subject of our illustration has, in common with its variety elegans, white star-like flowers that are very faintly dotted with pale pink spots near the base of the petals. The inflorescences rise to nearly a foot in height, and when they are fully grown they make a most effective display. Other good species with white flowers are in commerce, including S. Sternbergii, S. Stansfieldii, S. Whitlavii and its variety compacta, S. aquatica, one of the largest-leaved kinds, S. cæspitosa, &c. Apart from the white-flowered varieties mentioned, a new and increased interest has been added to the group under notice by the introduction a few years ago of that richly coloured variety known as "Guildford Seedling," presumably a chance seedling from S. Rhei, and which originated in the garden of the late Mr. Selfe Leonard at Guildford. Since the introduction of this excellent plant many varieties possessing coloured flowers have appeared, but none of these equal the "Guildford Seedling." S. Rhei and S. R. superba have pale pink and rose-pink flowers respectively. A distinct plant is S. muscoides purpurea. It is one of the most profuse in its flowering, and much the dwarfest in habit of those mentioned. All the kinds delight in moisture, some, indeed, as the British species now illustrated, being frequently found in bogs and swamps, but such wet conditions are not absolutely essential for plants under cultivation. *E. H. Jenkins.*

FLORISTS' FLOWERS.

GOLD-LACED POLYANTHUSES.

During the earlier years of the National Auricula Society's existence, good, named varieties of gold-laced Polyanthuses were fairly common. Now they are not seen at the southern shows of the society. Presumably these gold-laced Polyanthuses are dying out with the old florists, and whilst one cannot too greatly deplore the disappearance of that race of men who were enthusiastic florists, yet the decadency of the gold-laced forms of Polyanthus is to be little regretted, because even at their very best they were not striking flowers. To secure their special points in perfect form, they need the cool atmosphere of the north; in the south it is found difficult to produce them to perfection because of their sensibility to summer heat and insect attacks. As garden plants they have been displaced by the large-flowered and far more beautiful type represented by the fancy or border section. These, indeed, are amongst our most pleasing early spring flowers, and can be relied upon to reproduce from seed all the features of the finest strains. Unfortunately for the gold-laced forms, the best of the named varieties appear to have attained to a degree of perfection in marking beyond which no seedling could advance, and from which the majority are vastly inferior. The thrum or cluster of anthers set in a round golden cup, the centre of a pure yellow or golden colour, into which the lacing, fine or broad, which most perfectly margined the red or maroon ground, cut into clearly, made a combination of markings, when found as in Exile or Cheshire Favourite, not easily excelled. One may see thousands of seedlings of so-called gold-laced Polyanthuses to-day, but not one will bear comparison with the flowers of the old varieties once so cherished of the florists. *A. D.*

EVIL EFFECTS OF TIGHT LIGATURES.

It may be readily observed that if the branch of a tree is "ringed" by the removal of an annular piece of the bark cut down to the living tissue lying at the periphery of the wood, that a swelling occurs at the upper edge of the ring. This swelling is produced by the excessive growth of the living cells close to the margin of the tissue that has been severed. A similar swelling may sometimes be seen at the lower edge of the ring, but usually it is only trifling in extent. The chief reason why the cells at the upper margin develop in this luxuriant fashion is to be sought in the accumulation, above the ring, of the complex nutritive substances that are unable to wander further down the stem owing to the severance of the conducting tissues of the bast. For the substances in question are largely produced by the activity of the leaves, and normally traverse the bast or "phloem" of the stem, distributed to all parts of the plant wherever tissue wastage, or cell formation, is going on.

Every practical man is aware that a wound caused by the removal of a branch heals over more quickly and effectively the more cleanly the living tissues are cut, and the more closely it is severed to the trunk, or to a leafy branch of the tree. The reason is to be sought in the fact that in this way the proliferating living cells are not interfered with by leaving them covered with the remains of lacerated dead tissues, and furthermore the cells in question are thus situated close to the tracks along which nutriment can be readily conveyed to them.

The subject of our illustration clearly shows how undesirable it is to bind a growing stem too tightly. For the ligature not only causes a malformation of the shoot above it, but, by compressing the conducting channels in the bast, it may result in the starvation of the parts situated below it, and even the roots will also be affected if the main stem is thus ill-treated. The insidious character of the evil becomes obvious when it is remembered that the ill results will not be manifested for some time, inasmuch as it is not the water channels, but those conveying the

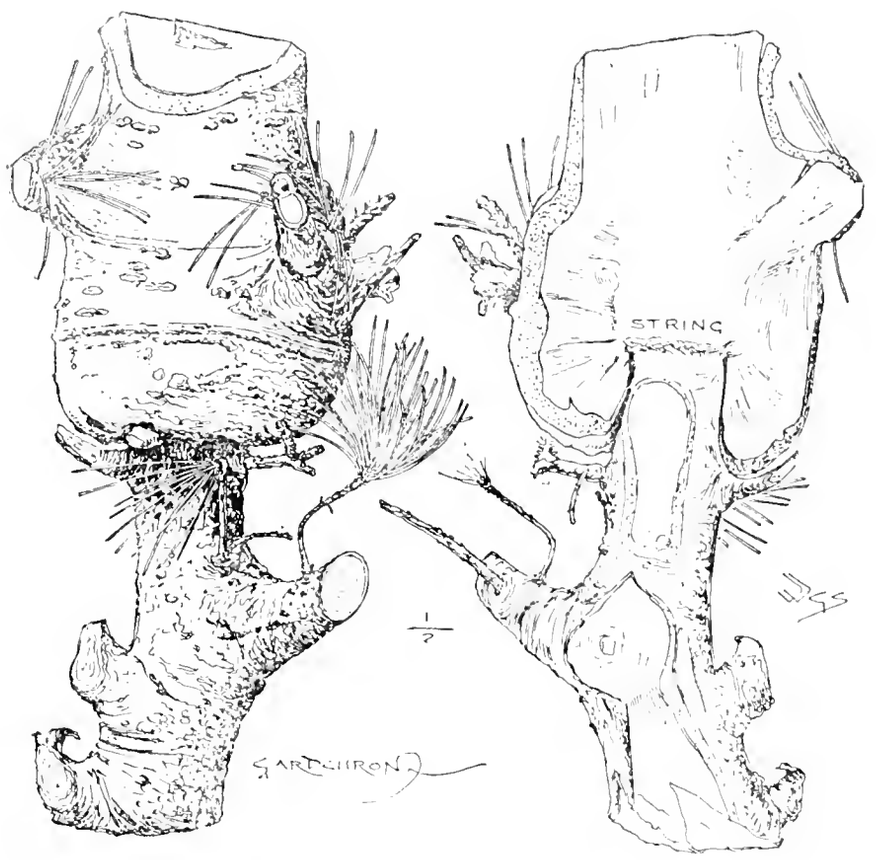


FIG. 136.—A CEDAR STRANGLED BY STRING.

This excessive cellular development normally occurs wherever the continuity of the rind is interrupted, provided that the necessary nutriment can reach the cells which are stimulated as the result of the injury, and so the healing of wounds in a tree is provided for by means of this reaction to the conditions introduced by the injury.

The illustration (fig. 136), shows an example, not very uncommon, where the conducting channels of the bast have been choked by a tightly-drawn string. The cells above the ligature have responded to the changed nutritive conditions by vigorous growth—by proliferation, as it is sometimes termed. Then, as the tissues began to differentiate in the cellular mass, a local increase of wood resulted, which gradually grew down along the twig, enveloping it in a sort of cylindrical pocket, exactly as the healing tissue may be observed to do when growing over a bit of exposed wood that may have been left as a snag when a branch has been broken off. manufactured food, which are thus choked. Hence the withering of the foliage, which at once directs attention to such damage as that caused by a check in the water supply does not occur, and so no timely warning of the mischief is given. *J. B. F.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

CYANIDING PLANT HOUSES.—Mr. Donoghue states (p. 269) "the strength of sodium cyanide compared with potassium cyanide is as 130 98." This statement is certainly misleading, because these figures are calculated on two totally distinct principles. The one is simply a commercial term; the other a true chemical expression. I fail to see any necessity for using the commercial term, apart from one thing, viz., to make the sodium cyanide appear to possess a much higher value over the potassium cyanide than it really has. If the percentage of sodium cyanide is expressed on the same basis that the potassium cyanide always is, and which is the correct one in chemistry, the 130 per cent. will be found to equal 98 per cent. purity. It is obvious that, if 100 parts of the salt is found to contain 100 parts of the compound, the salt must be absolutely pure, but when it comes to 101 per cent. there is no meaning in the statement. This high state of purity, viz., 100 per cent. cannot be expected in commercial salts, because it is a very expensive process to prepare the salt absolutely pure. If there is 95 to 98 per cent. it is as pure as can be expected, indeed, there is no need for further purity. Of the two compounds of equal purity, the sodium cyanide is one-third stronger than the potassium cyanide, but before the relative value of the two can be arrived at, the cost of each must be considered. The analytical data before me now of two samples, one of sodium, the other potassium cyanide, received from Mr. Luster, Nostell Priory, will serve as a good example for comparing the value. The sodium compound contained 92.49 per cent. actual sodium cyanide, and the cost is 4s. 6d. per lb.; the potassium salt contained 95.88 per cent. actual potassium cyanide, the cost being 3s. per lb.; 3 ozs. of sodium cyanide, at a strength of 92.49 per cent., yields 1.27 cubic feet of hydrocyanic acid: a similar quantity of potassium cyanide (95.88 per cent.) produces 0.99 cubic feet of the same gas. From these figures 2¾ ozs. of sodium cyanide (92.49 per cent.) would yield as much gas as 3 ozs. of potassium cyanide (95.88 per cent.). Then 2¾ ozs. of sodium cyanide at 4s. 6d. per lb. costs 7¾d.; 3 ozs. potassium cyanide at 3s. per lb. costs 6¼d.; 2¾ ozs. of sodium cyanide 98 per cent. would yield as much gas as the 3 ozs. potassium cyanide, and would cost 7½d. According to these figures, the potassium cyanide is the cheaper source of the gas. It is quite an easy matter to obtain from any chemist potassium cyanide at a strength of 95 per cent. I have been asked several times whether it is necessary to open the house three-quarters of an hour after closing. No, it is not. I leave the house closed all night with perfect safety. We have neither bug nor scale now, and it is a pleasure to look round and see the clear, healthy growth the plants are making. I have seen the same result in other gardens. I have letters from both gentlemen and gardeners on cyaniding from Wiltshire and Somerset to Glasgow. The results in nearly every case have been most gratifying. Little difficulties have been encountered by some, but they have been easily surmounted. Only two cases have come to my notice where any harm has been done—one in Northumberland where the gardener syringed his houses shortly before cyaniding, and there was no excuse for this, as the essential conditions have been stated again and again; the other case was in Yorkshire, where the gardener considered it unnecessary to weigh or measure his materials. *W. H. Dobson.*

WEATHER AT BERKSWELL IN RELATION TO THE FRUIT PROSPECTS.—Since writing my last note (see p. 268), we have experienced very wintry weather. Snow fell continuously on April 23, 24, and 25, forming the grandest sight of the kind I ever remember. The weather was so calm that every twig of bush and tree carried its complement of snow and represented fantastic appearances, but the weight broke the branches of many valuable trees. During the two days following the snowfall we had heavy rains, which quickly washed the snow away and at the same time caused our rivers, brooks, and streamlets to overflow their banks and flood all the low-lying meadows. On Saturday, May 2, we experienced a day of abnormal heat, and we were hopeful that a few days of such warm weather would prevail during the flowering and setting period of the respective hardy fruits, which are quite 10 days later than those of the Vale of Evesham. During the night, however, thunder, lightning, and torrential rain prevailed, and these conditions continued for the greater part of Sunday the 3rd inst. This again lowered our hopes for a good set of fruits, as the blossom is now at its most critical stage, and we have still to fear the early morning May frosts, should they unfortunately appear. Writing from memory, I think it is four years since we have had a general heavy crop of Apples in this county, and during that year many of these fruits were sold at £2 5s. 8d. per ton—i.e., at a

farthing per lb.; yet during that season American and Canadian (including Nova Scotian) Apples arrived in great quantities in this country, and found a ready sale, to the almost total exclusion of English-grown fruit, and they have held their hold on the British markets ever since. A few evenings ago I was at a public meeting when a speaker declared that in a few years this country would be entirely independent of supplies of Canadian or American Apples. I remember the late Mr. Barron telling me exactly the same thing nearly 30 years ago. Unless the climatic conditions of the British Isles change very much for the better, our position in the world as regards the cultivation and fruiting of the Apple is likely to remain very much the same as it always has been. Besides America and Canada there are other countries, including Tasmania, that in time will send an appreciable supply of Apples to our markets. Scientists are endeavouring to find some way of safeguarding the Apple crop through the frosts of April and May, and we have every reason to hope that they may succeed. *W. Miller, Berkswell.*

SOCIETIES.

ROYAL HORTICULTURAL.

APRIL 28.

(Concluded from page 290.)

Floral Committee.

Present: W. Marshall, Esq. (in the chair), and Messrs. Chas. E. Shea, C. R. Fielder, Jas. Douglas, W. J. Bilney, John Green, T. W. Turner, G. Reuthe, John Jennings, J. W. Barr, Walter Ware, Chas. Dixon, Arthur Turner, Chas. E. Pearson, Wm. Cuthbertson, J. T. Bennett-Poe, Herbert J. Cutbush, W. P. Thomson, E. H. Jenkins, W. J. James, Chas. T. Druery, R. C. R. Nevill, R. C. Notcutt, and Jas. Hudson.

Mr. L. R. RUSSELL, Richmond Nurseries, Surrey, displayed an extensive exhibit of Dracænas, Arahas, Bertolonias, Anthurium Scherzerianum, Ficus radicans, variegated variety, and other foliage plants of exotic species. As a separate exhibit, Mr. RUSSELL displayed a group of forced flowering shrubs and trees, all brightly and freely flowered. (Silver-Gilt Banksian Medal.)

Messrs. H. B. MAY & SONS, Upper Edmonton, showed miscellaneous flowering plants, including Roses, Herbaceous Calceolarias, Petunias, Cinerarias, Salvia splendens, "Pride of Zurich," and other species. (Silver Flora Medal.)

Messrs. HUGH LOW & Co., Enfield, Middlesex, made a bright exhibit with heavily flowered plants of Meterosideros floribunda, interspersed with which were plants of Genista elegans, while along the front hung long flowering shoots of Lotus peliorhynchus. Small Roses in pots were also included in this exhibit. (Silver Banksian Medal.)

Messrs. W. CUTBUSH & SONS, Highgate, London, N., showed many flowering shrubs, Roses, Carnations, Heaths, Spiræas, &c. In addition was a magnificent display of Carnations, staged with much taste (Silver-Gilt Banksian Medal.)

Mr. GEORGE MOUNT, Canterbury, made another charming display with cut Roses, every bloom of which was shown in first-class condition. (Silver-Gilt Banksian Medal.)

Messrs. R. & G. CUTHBERT, Southgate, showed a batch of forced flowering shrubs and other plants, which exhibited excellence of culture. The usual subjects were included in the display. (Silver Flora Medal.)

Messrs. WILLIAM PAUL & SON, Waltham Cross, Herts, showed plants of Roses, amongst which were many new introductions. One labelled Lyon Rose (H.T.) is of a beautiful shade of salmon-red; another named Albatross somewhat resembles the celebrated variety Frau Karl Druschki. (Silver-Gilt Banksian Medal.)

A display of pot Roses, all of which were climbing varieties, were shown by Messrs. FRANK CANT & Co., Colchester. (Silver Banksian Medal.)

Messrs. JAMES VEITCH & SONS, King's Road, Chelsea, showed flowering plants in variety, including Schizanthus, Cinerarias, Azaleas, Hydrangeas, the red-flowered Primula Cocklournia, &c. (Silver Flora Medal.)

Messrs. H. CANNELL & SONS, Swanley, Kent, made one of their characteristic displays of brilliantly-flowered Zonal Pelargoniums. (Silver Banksian Medal.)

Messrs. W. BULL & SONS, King's Road, Chelsea, showed ornamental-leaved plants of stove and greenhouse species.

Mr. C. F. WATERS, Balcombe, Surrey, displayed a pretty exhibit of Carnations, in a setting of Asparagus Sprengeri and Adiantum Ferns. (Silver Banksian Medal.)

Another exhibit of these popular flowers was put up by Mr. W. H. PAGE, Tangley Nurseries, Hampton. The pink variety Mrs. T. W. Lawson was exceptionally fine. The same exhibitor showed varieties of trumpet Lilies. (Silver Flora Medal.)

A large semi-circular group of Cinerarias was displayed by Messrs. JAMES CARTER & Co., High Holborn, London. (Silver Flora Medal.)

Messrs. J. CHEAL & SONS, Lowfield Nurseries, Crawley, showed varieties of Lilacs and branches of flowering shrubs.

A small but pretty exhibit was made by F. GODMAN, Esq., Horsham (gr. Mr. Moody). It was composed of the pretty Posoqueria longiflora, with Cantua dependens on either side, and trusses of greenhouse Rhododendrons.

Messrs. PAUL & SONS, Old Nurseries, Cheshunt, showed pot plants of Rhododendron Handsworthii "Early White," also Roses, Philadelphus in variety, &c.

Messrs. CARTER, PAGE & Co., 52, 53, London Wall, London, exhibited Violas in variety (Silver Banksian Medal), and another collection of these bedding flowers was shown by Messrs. DOBBIE & Co., Rothesay, N.B., who had also Pansies and a collection of named varieties of Polyanthuses. (Silver Banksian Medal.)

Mr. ROBERT SYDENHAM, Tenby Street, Birmingham, showed bulbous plants grown in moss fibre.

Clivias of improved varieties from the ordinary type were shown by W. SHUTER, Esq., Hampstead (gr. Mr. T. Armstrong). One labelled Hampstead Glory was carrying an exceptionally large truss of bloom, but the colour was not so deep as in the variety labelled Fire King. Inflorescences of several interesting plants were shown by H. J. ELWES, Esq., Colesbourne Park (gr. Mr. Walters); they included trusses of Cantua dependens, Alpinia nutans, Bomarea Caldasiana, &c.

Mr. JAMES DOUGLAS, Great Bookham, Surrey, showed three large plants of Myosotidium nobile, known by the popular name of the Chatham Island Forget-me-not.

A plant of Echium callithyrsum, about 6 feet tall, with woody stems, was shown by Mrs. BRIDGET TALBOT, Berkhamsted (gr. Mr. E. Pinnock). The flowers are of a brilliant Borage blue.

Collections of hardy flowers were shown by Messrs. T. S. WARE, LTD., Feltham; Messrs. R. WALLACE & Co., Kilnfield Nurseries, Colchester; Messrs. GEORGE BUNYARD & Co., Maidstone (Silver Banksian Medal); Messrs. JOHN PEED & SON, West Norwood, S.E., who also showed Gloxinias (Silver Banksian Medal); Mr. M. PRICHARD, Christchurch, Hants (Silver Banksian Medal); GUILDFORD HARDY PLANT NURSERY COMPANY, Guildford; Mr. G. REUTHE, Keston, Kent (Silver Banksian Medal); Messrs. J. R. BOX, West Wickham; Misses HOPKINS, Shepperton-on-Thames (Silver Banksian Medal); Messrs. G. & A. CLARK, Dover; Messrs. GEORGE JACKMAN & SON, Woking; and the Misses E. & M. KIPPING, Hutton, Essex.

Narcissus Committee.

Present: H. B. May, Esq. (chairman), and Messrs. W. Poupart, Chas. T. Digby, John Pope, J. Jacob, E. A. Bowles, H. A. Denison, E. Willmott, A. R. Goodwin, W. T. Ware, F. W. Currey, R. W. Wallace, Alex. W. Wilson, P. R. Barr, P. D. Williams, Chas. Dawson, W. A. Milner, Jan de Graaff, G. W. Leak, W. F. M. Copeland, J. T. Bennett-Poe, J. D. Pearson, H. B. Young, and C. H. Curtis (hon. secretary).

There were many fine groups of new Narcissi staged at this meeting, and novelties, beautiful, chaste and striking, were on all sides. No new variety, however, received an Award of Merit on this occasion.

A collection was staged by Messrs. BARR & SONS, Covent Garden, London, the group being rich in new varieties. (Silver-Gilt Flora Medal.)

Messrs. R. H. BATH, LTD., Wisbech, staged an interesting collection of good commercial kinds. (Silver-Gilt Banksian Medal.)

Messrs. CARTWRIGHT & GOODWIN, Kidderminster, had many delightful flowers in a nicely-arranged group. Chloe is a nearly pure-white, straight-crowned flower of the Queen of Spain type. Rising Sun has fine colour and substance. (Silver-Gilt Banksian Medal.)

Messrs. POPE & SON, Birmingham, showed many unnamed seedlings of merit. White Elephant (poeticus) is a very remarkable flower of great size and fine proportions. (Silver Flora Medal.)

Messrs. R. W. WALLACE & Co., Colchester, arranged a capital display of Tulips and Narcissus in many distinct kinds. (Silver Banksian Medal.)

Messrs. R. & G. CUTHBERT, Southgate, staged many vases of self-coloured Tulips in excellent condition. (Silver Banksian Medal.)

Orchid Committee.

Present: J. Gurney Fowler, Esq. (in the chair), and Messrs. Jas. O'Brien (hon. sec.), Harry J. Veitch, H. Little, W. Boxall, G. F. Moore, R. G. Thwaites, J. Cypher, J. Forster Alcock, W. Cobb, W. P. Bound, A. Dye, W. H. White, H. A. Tracy, Gurney Wilson, and J. Wilson Potter.

A remarkable display of specimens of Oncidium Marshallianum was made by J. GURNEY FOWLER, Esq., Glebelands, South Woodford, and for which a Silver Flora Medal was awarded; a Cultural Commendation was awarded to the gardener, Mr. J. DAVIS, for the same exhibit. The enormous plants were on rafts, and one specimen bore four branched spikes with innumerable large, bright yellow flowers. The finest in colour was the variety Davisii, which also had dark, red-brown blotches on the petals. A plant of Cypripedium (callosum Sanderæ × bellatulum album) was also shown, the yellowish colour was slightly marked with rose, the albino characters of the parents not being perpetuated.

HENRY LITTLE, Esq., Baronshalt, Twickenham (gr. Mr. Howard), was awarded a Silver Flora Medal for an effective group, in which were some good Lælio-Cattleya Hyeana, a plant of the variety splendens having nine flowers, &c.

Messrs. JAS. CYPHER & SONS, Cheltenham, received a Silver Banksian Medal for a group, in the centre of which was a large and intensely dark Lælio-Cattleya Dominiana.

Messrs. ARMSTRONG & BROWN, Tunbridge Wells, were voted a Silver Banksian Medal for an artistically-arranged group, in which were noted the rare Lycaste plana, Temple's variety.

Messrs. HEATH & SONS, Cheltenham, staged a group, which included a selection of Cypripediums, &c. (Silver Banksian Medal.)

Messrs. HUGH LOW & Co., Enfield, showed an effective group of Cattleyas, &c. Two of the best were C. Mendelii Virginius, a large, pure white variety with faint blush tint on the lip; and C. Percivaliana "Little Gem," white, with orange base to the lip. (Silver Banksian Medal.)

R. G. THWAITES, Esq., Chessington, Streatham (gr. Mr. Black), showed two plants of his large, pure white Cattleya Dusseldorfii Undine, Chessington variety; Lælio-Cattleya Wellsiana, Chessington variety, with white sepals and petals and violet front to the lip; and a small hybrid Odontoglossum.

F. MENTEITH OGILVIE, Esq., The Shrubbery, Oxford, sent Cypripedium Lawrenceanum Marjorie, a fine green and white variety resembling Hyeanum, but with a tinge of colour on the lip and sides of the dorsal sepal.

Mr. C. RAVENS, Odense, Denmark, sent Cattleya Schroderæ Mathii and C. S. var. L.-C. Ravens.

Sir TREVOR LAWRENCE, Bart., K.C.V.O. (gr. Mr. W. H. White), showed a pretty small West African Megaclinium with four spikes of very singularly formed flowers.

Fruit and Vegetable Committee.

Messrs. JAS. VEITCH & SONS, LTD., King's Road, Chelsea, showed a collection of 58 varieties of Apples and two dishes of Pears. (Silver Knightian Medal.) The same firm was granted a Silver Banksian Medal for an exhibit of Lettuces and Radishes.

The Rt. Hon. Lord HILLINGDON, Uxbridge (gr. Mr. A. R. Allan), showed three boxes of fruits

of Royal Sovereign Strawberry and a fruiting plant of the same. (Silver Knightian Medal.)

A Cultural Commendation was awarded to Mr. W. A. Cook (gr. to Sir EDMUND LODER, Bart., Leonardslee, Horsham) for an exhibit of Seakale.

Scientific Committee.

APRIL 28.—*Present*: Mr. E. A. Bowles, M.A., F.L.S., F.E.S. (in the chair), Dr. A. B. Rendle, Messrs. W. Cuthbertson, J. T. Bennett-Poe, J. W. Odell, H. J. Elwes, A. Worsley, W. Hales, and F. J. Chittenden (secretary).

Daffodil seedlings.—Rev. G. ENGLEHEART, V.M.H., sent the following communication concerning the white seedling Daffodils shown by him at the last meeting:—"During the past 20 years I have several times, in successive years, cross-fertilised Narcissus M. J. Berkeley ♀ on a considerable scale in order to obtain a race of early coloured N. incomparabilis, and in this I have been successful. But in each set, when it reached the flowering stage, there have appeared some of these white trumpets, virtually M. J. Berkeley itself, except in colour. There has always been also a sprinkling of yellow trumpets, i.e., M. J. Berkeley itself, reproduced from seed of a few flowers which escaped being totally disanthered, and the whites, I am convinced, originated in the same way. They were not produced by pollen of any white trumpet being conveyed to the stigma of M. J. Berkeley, and my reasons for this statement are: (1) no white trumpets were grown near, and few, if any, were in bloom so early as M. J. Berkeley; (2) early white trumpets, such as N. cernuus, invariably, in my large experience, modify the form of the ♀ parent; and (3) the appearance of flowers of this same character in every batch of seedlings points to a uniform internal cause in M. J. Berkeley itself. Not only the form of the flower, but the foliage, stature, general habit, and precise period of bloom are M. J. Berkeley in counterpart.

"The variety M. J. Berkeley was raised by Messrs. Backhouse about 1840, and is pretty obviously a self-fertilised seedling from N. maximus, which in its turn is a wild species indigenous on the French side of the lowland Pyrenees. I have had bulbs direct from the wild habitat, and have been in correspondence with a good botanist who has seen the plants in bloom there, but I have never heard of any white wild variety of N. maximus. I have myself raised from self-fertilised seed of N. maximus, a flower somewhat similar to M. J. Berkeley, and that form has no appearance in any single feature of being the result of a cross with one of the white trumpet section. Personally, I have no doubt whatever that this is a sudden 'spontaneous' break to white from yellow.

"The nearest analogy I can adduce is the occasional appearance of a pure white form in wild beds of the yellow Pyrenean N. muticus, quite reproductions, in every feature but colour, of muticus itself. No white trumpet Daffodil exists in the same zone as N. muticus, the little wild white N. moschatus being thousands of feet higher in a remote valley.

"I have no reason whatever to suppose that there is any white hybrid blood in the ancestors of M. J. Berkeley, i.e., that these white seedlings exhibit a reversion to ancestral character. It seems more likely to be an instance of a sudden 'mutation' from yellow to white in colour progress. It is interesting to note that precisely the same thing has been noticed in New Zealand in seedlings of M. J. Berkeley."

Seedlings of Gnetum.—Mr. W. HALES showed seedlings of Gnetum Gnemon grown at the Chelsea Physic Garden, exhibiting the foot which absorbs the food stored in the seed for the nourishment of the growing seedling; this foot is developed only to a very slight degree in some other Gymnosperms such as Ephedra.

Delayed flowering of Amaryllis.—Mr. ODELL showed some flower buds of Amaryllis Belladonna which were now appearing. The flowering had been delayed in many cases in the autumn, apparently through the short suitable season. Mr. Baker states that the normal period of flowering was in April in the native habitat, but this statement was called in question.

Floral malformations.—Mr. Bowles showed on behalf of Messrs. HOGG AND ROBERTSON, of Dublin, a malformed flower of Narcissus J. T. Bennett-Poe. The parts of the perianth and the stamens were each nine, and springing from the base of the style was a narrow tubular growth embracing what appeared to be a secondary style. This flower, and a double spathed Caladium, L. A. Van Houtte, somewhat similar in structure to the double spathed Richardia shown at the last meeting, exhibited by Messrs. J. VEITCH, of Chelsea, were referred to Mr. W. C. Worsdell for further examination.

Pyronia John Saden.—Messrs. J. VEITCH showed fruits of one of the hybrids previously exhibited before the committee in the autumn. The fruits of this hybrid were Quince-like in appearance, and had a remarkably pleasant aroma, but were still quite hard.

Snowdrop bulbs.—BRODIE of Brodie, Brodie Castle, Forres, sent two Snowdrops with the newly-formed bulbs produced at a distance of 2 inches above the original bulbs, with which they were connected by means of a tube formed by sheathing membranous leaves.

NATIONAL AURICULA & PRIMULA.

(MIDLAND SECTION.)

APRIL 29.—The ninth annual exhibition promoted by this Society was held at the Botanical Gardens, Birmingham, on this date. The weather was beautifully fine, and the attendance of members and visitors constituted a record.

The show was the largest and best ever held under the auspices of the Society, which is very gratifying to the committee, who are doing their utmost to increase the popularity of the Auricula in the Midlands.

Some choice flowers of both new and old varieties were shown; especially good were those sent by Mr. JAMES DOUGLAS, Edenside, Great Bookham, who won the Silver Medal offered by the Birmingham Botanical and Horticultural Society to the most successful exhibitor in the show. The Bronze Medal offered by the same Society to the exhibitor who had the second best results was awarded to Mr. C. WINN, Selly Park, Birmingham (gr. Mr. T. Sheppard). Two Silver Medals, viz., "The Willmott" and "The Brookes," were offered to local growers. The first of these was offered to the exhibitor gaining the greatest number of points in the show classes, and the other to the most successful exhibitor in the Alpine classes. Both medals were won by Mr. C. WINN. Of maiden growers in the section devoted to show varieties, Mr. G. D. FORD, of Acock's Green, was the most successful; and Mr. S. E. WILLIAMS, of Brierley Hill, took the lead in the Alpine classes. Honorary exhibits were contributed by Messrs. W. H. SIMPSON & SONS, Edgbaston, who showed Daffodils, and Mr. C. WINN, who staged an exhibit of Schizanthus.

SHOW VARIETIES.

The leading class was one for eight varieties, dissimilar, and this was contested by six exhibitors. The 1st prize was well won by Mr. JAMES DOUGLAS, who staged vigorous plants bearing large trusses of shapely flowers. The varieties were as follows:—Eucharis, Charm, Mikado, Abbé Liszt, Amy Robsart, Favourite, Mrs. Henwood, and George Lightbody. 2nd, Rev. F. D. HORNER, Kirkby Lonsdale, whose best varieties were Minnie Horner, Magpie, and Favourite.

In a class for six varieties, dissimilar, Mr. DOUGLAS again won the 1st prize with choice examples of Abbé Liszt, Greybag, Mrs. Phillips, George Lightbody, Shirley Hibberd, and Richard Headley. 2nd, Mr. C. WINN, Selly Park.

A class for four varieties, dissimilar, brought five contestants. Mr. W. H. PARTON, Hollywood, Birmingham, and Mr. T. M. EGLINGTON, Birchfields, Birmingham, being awarded 1st and 2nd prizes respectively.

In the similar but smaller class for two varieties, dissimilar, Mr. G. D. FORD, Acock's Green, was awarded the 1st prize for splendid plants of George Rudd and Gerald. 2nd, Mr. W. C. G. LUDFORD, Four Oaks.

SINGLE PLANTS.

Competition was keen in the classes provided for single plants, as many as 23 exhibits being staged in one class.—

Green-edged—1st, Mr. W. H. PARTON, with Mrs. Henwood. 2nd, Mr. W. M. SHIPMAN, Altrincham, with Shirley Hibberd.

Grey-edged.—Mr. W. M. SHIPMAN won the 1st prize with a grand plant of Richard Headley.

White-edged.—The 1st and 2nd prizes were won by Mr. DOUGLAS with Conservative and Acme respectively.

Selfs.—Mr. DOUGLAS again won the 1st and 2nd prizes in this class with Vanguard and Victor respectively.

In a class for a plant of either a Self, yellow Primrose, or orange buff colour, Mr. DOUGLAS was again placed 1st, with the variety Orient.

ALPINE AURICULAS.—These were well shown. Mr. J. DOUGLAS won the 1st prizes in classes provided for eight Alpines, and for six Alpines, whilst Mr. W. H. PARTON took the lead in the classes for four Alpines, and for two Alpines. Mr. PARTON also showed the best single specimen possessing a light centre. Mr. RICHARD HOLDING, Bournville, exhibited the best plant having a gold centre. Mr. HOLDING'S variety was named "Unexpected."

SEEDLING SHOW AURICULAS.—The Rev. F. D. HORNER showed the best pair of Show Auriculas, his examples being Flora and Orient. 2nd, Mr. W. SMITH, Bishop's Stortford, with Sunrise and Geraldine.

The Rev. F. D. HORNER'S Orient was adjudged the best green-edged variety, and Mr. W. SMITH'S Stately beat the last-named exhibitor's Graything in a class arranged for grey-edged varieties. The best Self was shown by Mr. DOUGLAS, who had Harrison Weir in superb condition.

FANCY AURICULAS, POLYANTHUSES, AND PRIMULAS.—Mr. W. C. G. LUDFORD, Four Oaks, gained the 1st prizes for (1) six fancy Auriculas, (2) six fancy Polyanthuses, (3) six hardy Primulas. Mr. J. STOKES, Harborne, was awarded the 1st prize in a class for single plants of gold-laced Polyanthus with the variety George IV.

AWARDS.

First-Class Certificates were awarded to each of the under-mentioned Auriculas:—

Vanguard (dark Self), *Harrison Weir* (red Self), *Orient* (yellow Self), *Mrs. James Douglas* (light centred Alpine), *Phyllis* (light centred Alpine). All the above varieties were shown by Mr. JAMES DOUGLAS.

Mrs. Sheppard (green-edged), shown by Mr. C. WINN, Selly Park, and *Jack Parton* and *Mrs. Parton* (both gold-centred Alpines), shown by Mr. W. H. PARTON, Hollywood.

PREMIER BLOOMS.—The premier Auricula was the example of George Lightbody, shown by Mr. J. DOUGLAS; the premier Alpine, Mrs. Danks, shown by Mr. C. WINN; the premier seedling Auricula, Harrison Weir, shown by Mr. J. DOUGLAS; and the premier seedling Alpine, Jack Parton, shown by Mr. W. H. PARTON.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

APRIL 16.—*Committee present:* Messrs. E. Ashworth, R. Ashworth, Ashton, Cowan, Cypher, Keeling, Parker, Shill, Warburton, Leemann, and P. Weathers (hon. sec.).

R. ASHWORTH, Esq., Ashlands, Newchurch (gr. Mr. Fletcher), staged a collection of Odontoglossums. Odontoglossum crispum var. "Our Queen of the Snows," a choice white form, was given an Award of Merit. O. × Lambeauianum var. Brittanica, and O. × L. var. vivians received similar awards. Cypripedium × Brittania (C. × Gowerii × C. nitens) was also granted an Award of Merit. (Silver Medal.)

H. J. BROMILOW, Esq., Rainhill, Liverpool (gr. Mr. Morgan), again staged a good collection of Cypripediums, prominent plants being C. × Baron Schroder, C. × bingleyense var. magnificum, C. × triumphans, Bank House var., C. × Wootonii and C. × majesticum, a new hybrid, the parentage of which is not recorded. The first-named plant was granted an Award of Merit, and C. × majesticum was awarded a First-Class Certificate. (Silver Medal.)

J. MCCARTNEY, Esq., Hey House, Bolton (gr. Mr. Holmes), was awarded a Bronze Medal for an exhibit of Cattleyas and Lælias and a Silver Medal for a miscellaneous collection of Orchids, in which were several good Cattleyas. A choice form of Cattleya Harrisoniæ was given an Award of Merit.

Mr. JOHN ROBSON, Altrincham, exhibited Dendrobium Wardianum var. Ochroleucum and Dendrobium nobile, Hardy's var.

J. J. HOLDEN, Esq., Southport (gr. Mr. Johnson), is a new exhibitor at these meetings. He received an Award of Merit for Brasso-Cattleya × Dorothy, the white form of Cattleya Warneri being the second parent.

G. SHORLAND BALL, Esq., Burton, Westmoreland (gr. Mr. Herdman), exhibited Brasso-Cattleya × Queen Alexandra, a plant that has been previously certificated.

A. WARBURTON, Esq., Hashmgden (gr. Mr. Dalgleish), exhibited Cypripediums in variety (Bronze Medal) and a group of Cattleyas and Lælias (Bronze Medal). Cattleya Schroderæ "His Majesty" and Cypripedium villosum "The Premier," the latter a flower of fine shape and size, were given Awards of Merit.

H. ARTHUR, Esq., Blackburn, exhibited two well-cultivated plants of Cymbidium eburneo-Lowii, and the reverse cross, the previous awards being confirmed.

J. H. CRAVEN, Esq., Kershley (gr. Mr. Corney), staged a collection of Miltonia Bleuana, all the plants being well flowered.

Mr. E. G. MITCHELL, Sale, staged a small exhibit of Dendrobiums.

E. ROGERSON, Esq., West Didsbury (gr. Mr. Price), exhibited Dendrobium × Dalhon-nobile, which the committee desire to see again. *P. W.*

SOCIÉTÉ D'AGRICULTURE ET DE BOTANIQUE DE GAND.

THE GHENT EXHIBITION.

(Concluded from page 289.)

We reproduce at fig. 137 a further illustration of the International Exhibition at Ghent, showing King Leopold and his suite, accompanied by the President of the Society (M. Callier), and others, traversing the garden which separated the Casino buildings from the temporary Annexe. His Majesty, who has visited these exhibitions for a period of 50 years, examined the exhibits with much care, his visit extending over two hours.

[Photograph by W. J. Lacey.

FIG. 137.—THE GHENT EXHIBITION. SHOWING KING LEOPOLD AND SUITE LEAVING THE ANNEXE. THE PRESIDENT, M. CALLIER, MAY BE SEEN DIRECTLY ON THE LEFT HAND OF THE KING.

THE BANQUET.

The banquet took place on Sunday, April 26, at five o'clock, in the great square hall of the Grand Theatre of Ghent, and this event closed the festivities organised for the entertainment of the members of the jury. More than 300 guests were present. Behind the chairman's table was placed a bust of the King, surrounded with Palms and other ornamental foliage plants. All the tables were decorated with flowers. The banquet was presided over by M. A. Callier, who was supported by M. Hellepute (Minister of Agriculture), M. Viger (Paris), Lord Redesdale, Van den Heuvel (late Minister of Justice), Lt.-General Delée, Chevalier Radaelli, M. Ruijs de Beerenbrouck, Dr. Kolb, MM. Braun (Mayor of Ghent), Cooreman (President of the House of Representatives), Begerem (late Minister), &c.

It was a great honour to Belgian horticulture that three Ministers of the Crown were present at this banquet!

M. Callier, on rising to propose the toast of "The King and Royal Family," alluded to the King having described himself as "an old gardener." He also spoke in very appreciative terms of the splendid collection of plants cultivated in the Royal Gardens at Laeken. It is for us, said he, the greatest patronage our Sovereign can give to horticulture. For many centuries our country was, unhappily, the battlefield of Europe. The nations of Central Europe very often came here to settle their disputes. Since 1830, however, Belgium had lived free and happily. The Ghent Horticultural Society was born whilst Belgium was under French rule. After Waterloo the Society still prospered under the Dutch Government. In its youth the Society had a powerful protector in King William, who visited the Ghent exhibition, and it should be remembered that the last act of the Society before 1830 was to vote a Gold Medal to King William as a mark of gratefulness. The Society's indebtedness to France and Holland was plain, and he (M. Callier) begged those pre-

sent to drink the health of the President of the French Republic and the Queen of Holland.

The band then played the French and Dutch National Anthems.

M. Callier afterwards made an allusion to the new Horticultural Department lately instituted by the Minister of Agriculture. He said that for years horticulture had no official guide, but that she had now a generous Minister to care for her. He was proud to speak of M. Helleputte's good qualities, and had the honour to propose the toast of "The President of the House of Representatives, the Members of Parliament for the Province, and the Authorities of the Town of Ghent." He drank to the health of M. Helleputte, to M. Braun, and the district authorities.

M. Helleputte thanked the eminent president for his kind words, and specially for the mention he had made of the Government's action in regard to the horticultural question. He was happy to be in such a company and in the city of flowers. Horticulture was a great industry, and, as understood at Ghent, it provided work for a greater number of men than agriculture. Horticulture would solve a great economical problem by occupying on a small piece of land many more hands than agriculture, and consequently by bringing the people back to the land. It was to the rural populations that Belgium owed its national prosperity. The considerable development of horticulture that has taken place has afforded me the opportunity of arriving at the decision to give horticulture what she most required, namely, a proper organisation. There is a Flemish proverb which says, "A man that gives what he can is an honest man," and I declare that I will do all I can in favour of horticulture. M. Helleputte then proposed the toast of "The President of the Society, M. Callier," and of "The Foreign Visitors."

M. Ceuterick (secretary) proposed the health of Lord Redesdale and M. Viger.

Lord Redesdale thanked M. Ceuterick for his kind words respecting England, and, turning his thoughts backward, spoke highly of the work accomplished by the late Count de Kerchove (president) and M. Fierens (secretary). The president had said that horticulture had not said its last word, that might well be the case, but his lordship thought it impossible for the Society ever to treat its guests more cordially than on the present occasion.

M. Viger proposed the toast of "Ghent and Ghent Horticulture."

M. Ruijs de Beerenbrouck thanked the President for reviving the memory of King William and for his reference to the present Queen of Holland. He referred to the work done in Holland by eminent horticulturists such as MM. Rodigas, Millet, Burvenich, Van Hulle, &c., and concluded by proposing the toast, "Belgium, Happy and Free, and the Societe d'Agriculture et de Botanique de Gand."

M. Braun (Mayor of Ghent) thanked M. Viger for the promises he had made to encourage France to exhibit at the Ghent International Exhibition of 1913. He would not say "Adieu" to the guests, but "*Au revoir*."

ABERDEEN NATURAL HISTORY AND ANTIQUARIAN.

HISTORY OF SCOTTISH PEAT MOSSES.

THE history of the Scottish Peat Mosses and their relation to the glacial period was described recently in Aberdeen University by Mr. Francis J. Lewis, F.L.S., lecturer in geographical botany, University of Liverpool, to the members of the Aberdeen Natural History and Antiquarian Society. Professor Arthur Thomson, of Aberdeen University, presided. With the aid of beautiful slides and diagrams, Mr. Lewis proceeded to point out that the present distribution of peat deposits in the British Isles showed a general tendency to follow the maximum rainfall, the deposits being comparatively scanty on the eastern side of England and Scotland, and increasing in area and thickness as the western coasts were approached: the greater development occurring in the Hebrides, the western part of the Scottish mainland, and the west of Ireland. In the hill districts they reached their greatest development upon smooth, flat-topped hills like the Pennine chain in England, the elevated plateau of the Grampian Mountains, and in elevated districts surrounded by mountains. The Highland mosses began their history at a later stage than the peat examined in the southern uplands. In the north, none of the beds below the Arctic plant zone of the southern uplands are present. As the valley glaciers and local ice-sheets in the Highlands began to pass away, a tundra-like vegetation spread over the ground, represented at the base of the peat in Caithness-shire, East Ross-shire, and Inverness-shire by thick beds. Later, the climate appeared to have become more genial; this was indicated by a widespread growth of shrubby Betula alba, well developed on some of the watersheds in Inverness-shire. Just before the pine zone was reached, the sphagnum remains began to contain abundant traces of the stems of Calluna, and this continued in the Scots Pine layer. After a time the Pine forest in its turn passed away, and was replaced by moorland plants, which had continued in the several areas down to the present day.

In the course of the discussion which followed, Mr. John Michie, His Majesty's factor at Balmoral, said he had wandered over the peat mosses of various parts of Scotland, and more especially on Upper Deeside. He mentioned the interesting fact that quite recently he had occasion to trench a piece of peat bog, and in the bottom he came across an Oak, usually called a Black Oak. It had fallen into soft ground, the underneath part being perfectly entire, while the upper half was covered with masses of peaty growth. The lower portion was solid Black Oak.

Mr. Alexander Copland, Aberdeen, said the Oak grew very abundantly in Buchan (the name given to the north-east district of Aberdeenshire) centuries ago, and had been found in some peat mosses there. Strange to say, the Scots Pine did not occur in the mosses in Buchan to any considerable height above sea-level—for example, on the slope of the Hill of Mormond.

DARLINGTON HORTICULTURAL.

APRIL 29.—The spring show of this society, held on this date, was one of the best seen for many years. The Society's silver challenge bowl is the premier prize of the exhibition, and it is offered for a collection of eighteen varieties of Narcissi blooms (not to include Polyanthus Narcissi), fairly representing the three groups—Magni-coronati, Medio-coronati, and Parvi-coronati. The possession of this trophy has alternated between Mr. E. OWEN and Mr. CARSON, the former securing it last year. On this occasion the competitors were Mr. W. MOORE, of Cleasby, whose exhibit was considered the better, and Mr. EDWARD WILKIN, of Croft. In the open class for cut flowers, Mr. J. Lester (gr. to SIR JONATHAN BACKHOUSE) received the 1st prize for a decorated dinner-table. Mr. A. A. HARROW, son of the hon. secretary of the Society, won 14 prizes, of which 11 were firsts, and he also exhibited, not for competition, two boxes of choice Alpine Auriculas. Another successful exhibitor, who is also a young member, was Mr. J. P. BENNISON.

The inclusion of many handsome non-competitive exhibits contributed not a little to the success of the exhibition.

LINCOLNSHIRE DAFFODIL.

APRIL 30.—The annual exhibition of this Society was held at Spilsby on the above date. The exhibition was first arranged for an earlier date, but the weather proved so unpropitious for the development of Daffodils that it was necessary to postpone the event.

The popularity of the Society's exhibition was manifested by the entries, which numbered no fewer than 112 as against 93 last year, and 80 the year before.

The three premier awards went to Mr. SHARP, Rev. H. G. HALES, and Mr. STAFFURTH, respectively. Mr. SHARP was closely contested by Mr. C. MILLER. There were 21 classes, but no entries were recorded for seedlings and Tulips.

DEBATING SOCIETIES.

ADDLESTONE, CHERTSEY, & OTTERSHAW GARDENERS'.—A meeting of this association was held on Tuesday, April 7, when Mr. W. Carpenter, of West Hall, Byfleet, read a paper on "Successes and Failures in Gardening." The chair was occupied by the president, Mr. G. M. Edwards. During the evening the secretary read some interesting correspondence which he had conducted with Mr. F. J. Chittenden, of Wisley, concerning the cause of, and remedies for, spot disease in Violets. Mr. T. Stevenson offered a criticism of a recent show of the Royal Horticultural Society, at Westminster, and Mr. Grant read some useful excerpts from a paper dealing with the culture of Japanese dwarf plants, published in the last issue of the Royal Horticultural Society's *Journal*. Messrs. Barrett and Costin, under gardeners, were awarded the 1st and 2nd prizes respectively offered for an essay on "Summer Bedding."

BRISTOL AND DISTRICT GARDENERS'.—The tenth annual meeting of this association was held on Thursday, April 23; Mr. I. C. House presided. The hon. secretary and treasurer, Mr. J. Scott, of Downside, read a very encouraging report of the year's proceedings; this was followed by the financial statement which records a balance in hand for the first time in the Society's existence. It is largely owing to the energetic services rendered by Mr. Scott that the Society is now in such a flourishing condition. Lt.-Col. Carey-Batten, high sheriff of Bristol, was unanimously re-elected president, and Mr. Shelton (Redland Lodge Gardens), and Mr. Shaddick were respectively elected chairman and vice-chairman for the ensuing session, the other officers being also elected. Five new members were elected. *H. W.*

CROYDON & DISTRICT HORTICULTURAL.—At the meeting held on Tuesday, April 7, Mr. Seabrook, of the Chelmsford association, gave a lecture on "Growing Peaches and Nectarines." The lecturer advocated shallow planting, and said the subsoil must be well drained. Young trees do not require a rich soil, but good fibrous loam with the addition of a little bone-meal. It is very essential to plant firmly. The rods should be of medium length and trained 4 to 6 inches from each other, which will allow sufficient space for the light and air to pass around the fruit. Disbudding when growth is about an inch long is productive of good fruit. Just before the flowers open the trees should be sprayed with quassia and soft soap at intervals to destroy aphis and other insect pests. As soon as the leaf-buds commence to expand soak the roots well with water. Thinning the fruit should be done on two occasions, leaving a space at the final thinning of 1 foot square between each fruit. Manuring should be moderate till stoning is completed, then more liberal feeding may be gradually given. Trees growing under glass require syringing several times a day, whilst those on walls outside should be sprayed with clear water twice a day.

——— At the meeting of this association, held on March 21, Mr. H. Withers, South Croydon, delivered a lecture on "Insect Pests of the Garden." In a previous lecture he dealt with the external formation of these small animals, and on Tuesday he confined his opening remarks to the internal structure. Like some birds, insects may be found bearing a close resemblance to the bark of trees, whilst some caterpillars closely resemble the twigs of trees, and this forms a protection to them against birds who feed on them. There are also insects which, at first sight, one would take for moss, for they are fashioned in structure and appearance very like the mossy haunts they frequent. Oftentimes one hears a remark that cold easterly winds bring with them blight, but this is not so; the cause is simply very slow growth in vegetation, which renders it more susceptible to attacks from insect pests.

GUILDFORD AND DISTRICT GARDENERS'.—A meeting of this association, presided over by A. R. Upton, Esq. (president of the association), was held on Tuesday, April 21, when Mr. J. Clark, of Bagshot, gave a lecture on "Hardy Trees and Shrubs." The lecture was divided into five sections, embracing woodland or ornamental deciduous trees, evergreen trees, small flowering trees, deciduous flowering shrubs, and evergreen shrubs. A large number of new and choice varieties of trees and shrubs, in addition to many of the commoner kinds, were mentioned. *J. G.*

SALISBURY AND DISTRICT GARDENERS'.—This Society concluded the session, 1907-08, on April 29, with the annual dinner, when considerably more than 100 members and friends assembled. In the unavoidable absence of the president, Col. Sinclair presided. The Society may be congratulated upon the success of the past session both in respect of increased membership and the high quality of the lectures given. *W. Y.*

WARGRAVE AND DISTRICT GARDENERS'.—At the last meeting of the above association another of the successful competitions organised by the committee took place. A large number of members were present to witness the contests which were very keen. Ten entered in the Journeymen's class for arranging a large vase with Daffodils and foliage for effect. The 1st prizewinner was Mr. E. Collier. In the Head Gardeners' and Foremen's class six persons entered. The competition was for the arrangement of five vases for a table decoration. Mr. J. Goddard's (Parkwood Gardens) arrangement was declared the best. The flowers were afterwards forwarded to the Royal Berks Hospital.

CATALOGUES RECEIVED.

DICKSON & ROBINSON, Cathedral Street, Manchester—Dahlias, Chrysanthemums, herbaceous and bedding plants.

JOHN E. KNIGHT, Wolverhampton—Dahlias.

ABBOTT BROTHERS, Southall, near London—Bee Hives and appliances.

JOHN R. BOX, West Wickham, Kent—Begonias.

CHEERANS, Hale, Manchester—Dahlias.

LEWIS HILLIER & SONS, The Nurseries, Winchester—Nursery Stock.

THOMAS S. WARE, LTD., Feltham, Middlesex—Bedding Plants.

DICKSONS, LTD., The Nurseries, Chester—Bedding Plants, Dahlias, &c.

JOHN PEED & SON, West Norwood, London, S.E.—Begonias' Caladiums, Gloxinias.

THE WEATHER.

The Following Summary Record of the weather throughout the British Islands, for the week ending May 2, is furnished from the Meteorological Office:—

GENERAL OBSERVATIONS.

The *weather* varied greatly. During the major part of the period it was rainy and cold, but late in the week it became fine and unusually warm over England and Ireland. Quite at the end of the period, however, it again fell into an unsettled condition, and thunderstorms were experienced in several parts of north-western and central England, as well as at Guernsey. An aurora was observed at Shaftesbury on the 26th.

The *temperature* continued generally low in Scotland, but over England and Ireland a very sudden rise occurred on Friday. The mean for the week was below the average in Scotland and the northern districts of England, above it elsewhere. The highest of the maxima were recorded on May 1 or 2, except at a few stations in Scotland. In the English Channel and in England N.W (at Jersey and Bettws-y-Coed on the 2nd) the thermometer rose to 78°, while in the other districts the maxima ranged from 76° in England S.E. and the Midland Counties, and 75° in England E. and S.W. to 56° in Scotland N. During the early days of the week the readings were below 50° in many parts of England and Ireland. The lowest of the minima, which were registered on the 27th at a few stations, but generally on the 26th, ranged from 22° in Ireland N. (at Markree) and 24° in Scotland W. and Ireland S. to 31° in England N.E., and to 34° in the English Channel district. The lowest readings reported on the grass were 12° at Markree, 17° at Cambridge, 18° at Douglas, 19° at Llangammarch Wells, and 20° at Birmingham, Colmonell and Armagh.

The *mean temperature of the sea*.—The water was again colder than during the corresponding week of last year on almost all parts of the coast, the difference being at least 2° in many places and nearly 4° at Cromarty. The actual figures for the week varied from about 49° at Newquay and Ballyglass to 41·5° at Cromarty.

The *rainfall* exceeded the normal except in Scotland N., and in all districts except Scotland E. the excess was either considerable or very large. Falls of more than 0·5 inch were common in the western and north-western districts, the heaviest reported being 1·0 inch at Pembroke on Monday, 1·0 inch at Liverpool on Tuesday, 1·1 inch at Roche's Point, and 1·0 inch at Douglas and Valencia on Wednesday, and 1·2 inch at Birmingham (during a thunderstorm) on the night of Saturday.

The *bright sunshine* was less than the average, the deficit being rather large in most districts. The percentage of the possible duration ranged from 41 in the English Channel and 38 in England S.E., to 20 in England N.E. and to 13 in Scotland E.

THE WEATHER IN WEST HERTS.

Week ending May 6.

A leap from midwinter to midsummer.—During the recent cold period at the end of April the temperature in the thermometer screen on two successive days never rose higher than 41°, whereas on the 1st and 2nd of the present month the same thermometer registered respectively 76° and 77°—a difference of 36°. In explanation of the above heading I may state that a maximum temperature of 41° represents a cold day in the middle of January, and a maximum temperature of anything above 71° a warm day in the middle of July. Since the two warm days above referred to the day temperatures have rapidly declined. All the nights during the week, however, proved very warm for the time of year, the exposed thermometer never falling lower than 40°. The temperature of the ground is now about seasonable, both at 1 and 2 feet deep. Rain, snow, or hail has fallen on all but two of the last 17 days, and to the aggregate depth of 3¼ inches—equivalent to a fall of 16½ gallons on each square yard in this district. Of that amount 11 gallons has come through the percolation gauge on which short grass is growing, and 13½ gallons through the bare soil gauge. The sun shone on an average for 3¾ hours a day, or for 1¼ hour a day less than a seasonable duration for the beginning of May. The winds were again light—the mean velocity in the windiest hour being only 11 miles. The average amount of moisture in the air at 3 o'clock in the afternoon exceeded a seasonable quantity for that hour by as much as 14 per cent. A wild Cherry tree growing in my garden came first into blossom on the 1st, which is 14 days later than its average date for the previous 22 years, and later than in any year since 1891, or for 17 years.

April.

Exceptionally cold and wet. Snow six inches deep. This was the coldest April since 1891, or for 17 years. The days were, as a rule, more unseasonably cold than the nights. In fact, there were only five warm days during the month. On the warmest day the temperature in the thermometer screen rose to 62°, and on the coldest night the exposed thermometer registered 14° of frost. Both of these extreme readings are very low for April, and more particularly the highest day temperature. Rain, snow, or hail fell on as many as 20 days, and to the aggregate depth of 3⅔ inches, which is 1¼ inch in excess of the April average, and making this the wettest April since 1882, or for 26 years. During the last 12 days of the month, which proved exceptionally cold, wet, and sunless, the ground was covered with snow on four days to the average depth of 1 inch, 6 inches, 1½ inch, and 2½ inches respectively. Only on one previous occasion in the last 22 years has the ground been covered to any measurable depth in April, and then only to the depth of an inch. The record of sunshine, taking the month as a whole, was about average. This was rather a calm April. During the windiest hour the mean velocity reached 21 miles—direction west. For as many as 342 hours, or for 14 days, the direction was some point between north and east. The mean amount of moisture in the air at 3 p.m. exceeded a seasonable quantity for that hour by as much as 10 per cent. Indeed, I have no previous record of the atmosphere being as generally humid in April during the last 22 years. *E. M., Berkhamsted, May 6, 1908.*

Answers to Correspondents.

Aquilegia ecalcarata: *C. D.* This name is merely a synonym for the common Columbine, A. vulgaris. There is no authority for the name, which is one of garden usage only.

Begonia Tubers: *B. R. D.* The tubers are affected with the Tulip mould, Sclerotinia parasitica. The varieties you mention as having been attacked are probably more susceptible to the disease than are the others of your stock. Burn all those that are infected, and dust the apparently sound tubers with sulphur.

Employment in the London Parks: *M. T.* In the case of the Royal parks, application forms may be obtained from the respective superintendents. For employment in the parks and open spaces under the control of the London County Council, apply to Colonel Sexby, Parks Department, London County Council, 11, Regent Street, London. With regard to the prospects of advancement in public gardening, this, as in other branches of the profession, will largely depend upon a person's ability and aptitude in that direction. Most towns of any considerable size have one or more parks, and their number will no doubt be increased, for they are very popular with the public.

French Horticultural Journals: *M. L. L. Revue Horticole*, published at Rue Jacob, 26 Paris, is a high-class paper issued fortnightly; its illustrations of plants, many of which are coloured, have a high reputation. The yearly subscription is 22 francs, post free. *Le Jardin* is published weekly, and in style more generally resembles our weekly gardening papers than the former. It is published at 84 bis, Rue de Grenelle, Paris. The yearly subscription is 14 francs, post free.

Fruit Buds Injured: *C. D.* The blossom buds were very much withered when they arrived, and as no pest has been found it is difficult to account for the trouble. It may perhaps be due to frost. If you will send us examples of the insects we will endeavour to oblige you. Meanwhile, as you suspect it to be the work of insects, spray the trees with some insecticide such as Extract of Quassia or one of the poisonous arsenical compounds, such as Paris Green.

Fuel for a Range of Greenhouses: *H. S.* If you will furnish us with the length of each of your five houses—which, you say, are heated by 400 feet of 4-inch piping, giving the number of hot-water pipes in each house, and the type and size of the boiler—we shall be better enabled to give you a correct estimate of the quantity of fuel you will require.

Japanese Plums: *F. H.* Allow the plants to remain in the cool house in which you have placed them until they are well established. In the meantime prepare a site for them at the foot of a wall facing to the south or south-west, by excavating holes 2 feet deep and sufficiently wide to accommodate the roots without crowding. Place in the bottom of the hole, for drainage purposes, a layer 6 inches deep of brickbats or coarse gravel, covering this with thin turves, placed grass-side downwards, for the purpose of preventing the finer soil from choking the drainage. Fill the hole with a compost consisting of three-parts rich fibrous loam and one-part horse-droppings, with a quantity of old mortar rubble or wood ashes, the whole to be well mixed together. When the young trees are well established, plant them outside in their permanent quarters. The varieties you mention—Red June, Abundance, Satsuma, Burbank, and Ogon—are all to be recommended, their fruits ripening (with the exception of those of Satsuma) in June and July. The fruit of Abundance (syn. Botan) is oblong, the yellow colour being flushed with cherry-red; the flesh is orange-yellow and perfumed. Burbank is cherry-red in colour mottled with yellow; in shape usually globular. Satsuma, or Blood Plum, is the best of all the Japanese varieties for cultivation in this country, being hardiest and most vigorous; the fruit is large and delicious, and, unlike the majority of Plums, the flesh is red; the fruits ripen in September. These Plums, like our own, are of the genus Prunus, and have nothing whatever to do with Diospyros.

Names of Flowers, Fruits and Plants.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. *Correspondents not answered in one issue are requested to be so good as to consult the following numbers.*

Plants: *A. C.* Sphaeralcea Munroana (Malva Munroana)—*J. N., Dublin.* Both are forms of Dendrobium Pierardii.—*Hortus.* Dendrobium stuposum.—*T. T.* Skimmia japonica, male form.—*R. T. H.* Dendrobium Devonianum.—*A. B.* 1, Dendrobium transparens; 2, Dendrobium primulinum; 3, Eria convallarioides; 4, Aerides virens.—*T. T.* 1, Oncidium flexuosum; 2, Brassia verrucosa; 3, Oncidium triquetrum.—*R. J. F.* Dendrobium transparens—*R. W.* 1, Primula verticillata; 2, Begonia hydrocotylifolia; 3, Begonia incarnata.—*A. D. W.* Sagina procumbens [Creeping Pearl wort].

Paris Horticultural Exhibition: *M. L. L.* (1) The Spring Show of the National Horticultural Society of France will be held on May 22 to 29, in the Cours la Reine, Paris. (2) The Fellows' pass of the Royal Horticultural Society does not admit to shows other than those announced on the card.

Rust on Mint: *F. W. C. S.* The red pustules are caused by a fungus known as Puccinia Menthæ. Cut the plants down to the ground and burn all the shoots removed. Spray the soil about the plants with a rose-red solution of permanganate of potash and repeat this at intervals.

Strawberries Attacked by Grubs: *G. P.* The insects attacking your plants are larvæ of one of the weevils, which are voracious pests to many plants. The perfect grub is just as injurious to plants, and you should therefore make every effort to extirpate them. They may be trapped by pieces of Potato, Carrot, or similar vegetables placed in their haunts. A dressing of Vaporite should be given if the area of your Strawberry beds is large, and when the ground has been grubbed of the plants afford a dressing of gas lime.

Tomato with Yellow Leaf: *F. P.* There is no disease present in the leaves. Afford the plants some nitrogenous stimulant at the roots; an occasional dose of liquid manure and soot water should prove beneficial.

Tulips diseased: *J. H. R. N.* The plants are attacked by the mould disease, Sclerotinia parasitica. Burn all the diseased bulbs, and do not plant Tulips on the same ground again until it has been treated with quicklime, after which it will require to lie fallow for a period.

Vegetables for Market: *P. W. F.* We have no knowledge of the writer of the article you mention, but would suggest your writing to the editor of the paper in which it appeared. It is our opinion, however, that it is much easier to write about making £500 a year per acre by growing vegetables than to do so in practice. Articles similar to this often appear in the lay Press, but are not seriously regarded by practical men.

BOTANICAL INSTITUTIONS OF GENEVA.

THOUGH the whole scientific world has associated the name of de Candolle with Geneva, and although many botanists are aware that Edmond Boissier, the author of the *Flora Orientalis*, lived and died at Chambésy, just outside of the town, it is not generally known that in no other place in the world are there so many botanical institutions with fine herbaria and libraries as at Geneva, and that at the Conservatoire Botanique there are now collections of dried European plants which compare favourably with those at Paris, Berlin, Vienna, or London.

It may be interesting, therefore, to say a few words about the four establishments, together with some remarks upon the new botanical gardens and fine Alpine rockeries.

The famous de Candolle Herbarium and Library is situated in the picturesque Cour de St. Pierre, facing the facade of the cathedral and a few of the fine old Elms, which help to give additional beauty to some of the streets and squares of Geneva. The original 14th century house was bought about 1785 and added to by August de Candolle, the father of Pyrame, the world-renowned author of the *Prodromus*, grandfather of Alphonse de Candolle, the authority on geographical botany, and great-grandfather of Monsieur Casimir de Candolle, the present head of the family, who was so good as to give the writer a few particulars concerning the history of the house. He pointed out a corner window which his great-grandfather had put into the back wall, so that he could see the Hôtel de Ville (Town Hall), and in case of disturbance, signs were exchanged between de Candolle as Premier Syndic or Chief Magistrate, and the other authorities, the times being very much disturbed. Geneva was at that time a republic, but in 1796 it was annexed to France for a period.

It may be mentioned here that Pyrame de Candolle, who began the *Prodromus* (continued by his son and finally finished by his grandson), was Professor of Botany at Montpellier University in the South of France, and Director of the ancient botanical garden there, and afterwards he laid out a garden at Geneva according to the natural system of classification.

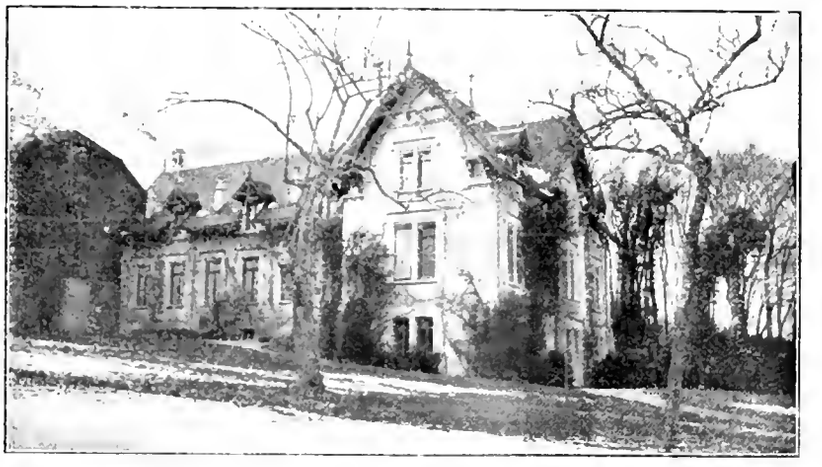

FIG. 138.—THE "BOISSIER" HERBARIUM NEAR GENEVA.

The Candollean Library ranks with that at Kew in being one of the best and largest botanical libraries in existence. It contains more works on general botany than are found at Kew, but is not so rich in works on pure systematic botany as either Kew or the British Museum.

There is a smaller but very good library of botanical books and works of travel at l'Herbier Boissier at Chambésy, two miles out of the town on the road to Lausanne. We give a view of a portion of the pretty house called Les Jordils, which was built by Mons. William Barbey in memory of his father-in-law, Edmond Boissier, a few years after that great botanist's death. The situation of the building on a grassy slope above the blue Lake Leman, with the most superb view of the Mont Blanc *massif* and several smaller but very imposing ranges in front, leaves nothing to be desired; and he is a fortunate man who has had the pleasure of working as a visitor in this comfortable building and with such surroundings to appeal to his artistic taste.

L'Herbier Boissier probably contains the finest collection in the world of plants from the Orient, and most of the type-specimens of the *Flora Orientalis* are naturally found there. Boissier's herbarium remains just as he left it, as does Pyrame de Candolle's herbarium referring to the *Prodromus*. At Chambésy, all modern additions have gone to form what is called the Barbey-Boissier Herbarium.

The excellent monthly *Bulletin de l'Herbier Boissier*, edited by Mons. Gustave Beauverd, the keeper of the herbarium, is printed and published in Geneva, and it is the only work of its kind in Switzerland.

It is a most fortunate thing, not only for Genevese botanists, but for botanists all over the world, that these two great private institutions should belong to wealthy families, who realise the responsibility of wealth, and are ever ready to lay the resources of their botanical establishments at the disposal of serious students of any nation.

We hope on a future occasion to say a few words about Mons. Wm. Barbey's Alpine garden at Valleyres in Canton Vaud, for most of the rockeries were the work of Boissier himself, and some of the plants are of great interest.

Half-way between Les Jordils and the town of Geneva is the Conservatoire Botanique and the new Botanical Gardens, which are placed under the able directorship of Dr. John Briquet, already a voluminous writer and a great traveller, who was responsible more than any other man for what are known as the "Vienna Rules" of botanical nomenclature agreed to at the 1905 International Congress at Vienna.

The Conservatoire Botanique is not a picturesque building like Les Jordils, although it is improved in appearance by the head gardener's little house adjoining. It is a massive rectangular erection of three floors and basement, admirably arranged for its purpose. The main portion of the building consists of wide galleries on each floor surrounding an open area or well, as is the case at the Kew Herbarium.

The new conservatoire was opened with great éclat in September, 1904, the inauguration being attended by botanists from many countries.

The chief jewel in the crown of Geneva's public botanical establishment is the great Delessert Herbarium, which was given to the town in 1869 by Benjamin de Lessert's sister-

in-law and her two daughters, the Baroness Hottingner and the Baroness Bartholdi. A fine portrait of Benjamin de Lessert has recently been given to the town by Mons. Emile Burnat, of Vevey, the author of the *Flore des Alpes Maritimes*, together with a striking portrait, by the same artist, of the generous donor.

Last winter Mons. Burnat's magnificent European herbarium was installed at Geneva, so that now the conservatoire has absolutely no rival, as far as its European collections are concerned.

But, like similar institutions in other countries, it lacks funds, and it was sad to see so large and finely-fitted a building with only a Director and one skilled assistant; but the staff has quite recently been increased by the addition of a cryptogamic specialist.

A remarkable collection of photographs and other portraits of botanists of various nations adorns some of the corridors. The library is as yet a little disappointing, but students are always free to consult the great Candollean Library, or that at l'Herbier Boissier, if they cannot get the book they want elsewhere.

The Botanical Gardens occupy about 75,000 square mètres—perhaps 16 acres—of land,

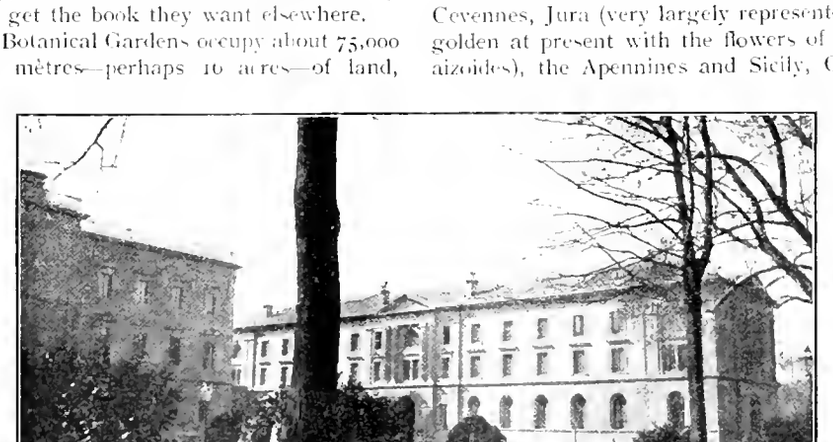

Fig. 139.—University and Natural History Museum at Geneva.

overlooking the lake and separated by the railway from the Ariana Park. They comprise a systematic garden, with the plants arranged according to Engler and Prantl, a young arboretum, and a very fine Alpine garden arranged in geographical groups.

I have seen many botanical gardens in Central and Western Europe, but never an Alpine garden arranged in such thorough geographical order as the Geneva garden; but, for beauty and neatness, I know nothing that equals Kew Gardens or Messrs. Backhouse's Alpine rockeries at York, or even the Edgbaston Botanical Gardens at Birmingham.

In fact, landscape gardening, as practised in England, seems hardly to be understood on the Continent, though Geneva has made a good start, and there is great need for it, particularly in France. Even a good lawn or a well-drained field of fine old turf is a rare thing on the Continent. On the French Riviera, a landscape gardener understanding his business and knowing a little French, would do a thriving trade just at present, for much land is being developed for building purposes, particularly in the Bay of Cavalaire.

But to return to Geneva, it may be interesting to give an outline of the arrangement of the Alpine garden. The culminating rocks are those of the Swiss Alps, three groups comprising the flora of calcareous regions, and two granite masses representing the crystalline rocks. Large clumps of Erica carnea give colour to these rocks just at present. Passing in a south-western direction, we observe several rockeries for the Western Alps (Savoie, Dauphiné and Piedmont), and then one for the Maritime Alps, and a large mass for the Pyrenees, with various endemic species. Near them come the Spanish Peninsula and Atlas Mountains. To the north-east, we find the following groups: Eastern Alps, Carpathians, and Balkans, with the curious Thlaspi cochleariforme in full bloom, the Caucasus (Helleborus caucasicus, Symphytum grandiflorum, &c.), the Orient, the Himalayi, Altai and Siberia, Thibet and China, with the pretty Primula sibirica in both the last two rockeries, and Japan.

Among the less important groups are the Central Plateau of France, the Vosges, Cevennes, Jura (very largely represented and golden at present with the flowers of Draba aizoides), the Apennines and Sicily, Corsica and Sardinia. Towards the lower end are the isolated masses of the New Zealand Alps, with their shrubby Veronicas, the Andes, and North America, the plants of North America being richly represented.

During the first week in April there were not many plants in bloom, but, in addition to the few already mentioned, were fine patches of Anemone Halleri from the Vosges, &c., Pulsatilla pratensis, Helleborus viridis and fœtidus, as well as the prickly-leaved H. caucasicus, Potentilla micrantha from the Jura, and the pretty yellow flowers of the Siberian Adonis amurensis.

A stream of water emerges from a grotto amidst the highest rocks of the Swiss Alps, and descends in zigzags across the Alpine garden to a small lake, where various aquatic plants are grown.

Altogether, the designer of this Alpine garden has shown very great skill, with the result that it is the most interesting, natural and picturesque I have seen abroad, and in a few more years it will doubtless improve.

At fig. 130 is a photograph of a part of the University with the Natural History Museum on the right. Dr. Chodat is the Professor of Botany, and lucky are the students—Swiss, Russian, Roumanian, Armenian—who, for the smallest of fees, come under the influence of so remarkable a man and so enthusiastic a botanist! At the present time, the Professor is conducting a party of energetic students among the wilds of Spain. A journey of this character, undertaken at a minimum cost, is an annual occurrence for Prof. Chodat and some of his fortunate pupils. *H. S. Thompson.*

RHODODENDRONS AT THE GLEN.

There are few gardeners in the northern part of this country who are not acquainted with the magnificent specimens of Azalea indica and greenhouse Rhododendrons that have been exhibited frequently at the shows of the Royal Caledonian Society in Edinburgh from the Glen Gardens, Innerleithen.

Those who have seen these plants have doubtless been impressed not only by the enormous quantity of bloom borne by each shrub, but also by the number of flowers composing each truss, and the size and superiority of the individual flowers.

The following are the cultural methods which were practised by the late gardener, Mr. MacIntyre:—The potting compost is for the most part peat, but there is also one-third fibrous loam, and a little sharp sand. The principal manures used are ground bones and Thomson's fertiliser, the latter being employed principally as a top-dressing. Several years are allowed to elapse before the plants are repotted. This operation is carried out during the early spring, previous to the formation of the young roots. A general top-dressing is given occasionally, but not oftener than once in two years. The reason they are not top-dressed oftener is to secure a very large plant in a particularly small pot. Manurial stimulants are, however, afforded in the form of liquid cow, sheep, guano, and soot manures. Liquid sheep manure and soot together are unequalled for the purpose of feeding, and this manure is applied copiously during the growing season and while the flower-buds are swelling, more especially at the former period, for this is one of the secrets of successful cultivation. After flowering the plants are stripped of all seed-vessels. The house, which is obscured from the direct rays of the sun, is closed in the afternoon, when the plants are given a heavy syringing, and the temperature allowed to rise to 75°, falling gradually to a night temperature of 63°.

A little warmth is maintained in the hot-water pipes during the night. After six or eight weeks of this treatment, the plants develop an even and vigorous growth. The temperature is afterwards lowered gently, and in the autumn the house is kept as cool as possible.

Sufficient warmth to prevent frost is preserved in the house during the winter months. Careful watering must be practised, for sour soil means disaster. Too much drought causes the shrubs to be infested with thrip. This pest may be destroyed by fumigations with the XL-All compound. Most of the plants at the Glen are about 6 feet in height, except one of R. Countess of Haddington, which is from 7 to 8 feet, and about 7½ feet in diameter at the bottom. This plant was awarded a Silver Medal in 1895 at Edinburgh. The best varieties of greenhouse Rhododendrons in these gardens are fragrantissima, Veitchianum, Princess Alice, Edgworthii and ciliatum. The Azaleas include the varieties Bernhard Andreas, of which there are two very large plants, Dr. Moore, Souvenir de François Vervaene, Paul Weber, Niobe, Empress of India, Mammoth, and others. *James P. Dickson.*

VEGETABLES.

CELERIAC OR TURNIP-ROOTED CELERY.

I WAS glad to observe an article in the issue for April 25 last, calling attention to Celeriac as a winter salad, well suited to our climate, in so far as regards our warmer counties, and on south borders in most of the others. With reference to the time of the main sowing, and the information afforded by the note to which I have alluded concerning the manuring of the soil, transplantation from the seed bed or seed box to the nursery bed or boxes, there is but little need to add anything; for if the directions there given are carried out in a workmanlike manner, the gardener will have sturdy plants for transplanting permanently in the month of May.

There is a malady which affects the plants after being laid-in in their winter quarters in October or November, viz., a browning of the substance of the tuber, a malady that is not uncommon on the Continent. In order to prevent the occurrence of this serious disfigurement, there is one radical remedy, namely, thorough applications of water, so that no check may happen in the chief season of growth, but manure water must be afforded with the utmost caution. The smallest sorts of Celeriac may not be injured in tenderness and good keeping quality by one early application—say in June or July—of fairly strong manure water. If the soil has been well dressed before digging, and afforded strong manure water before planting out the plants, it will need only clear water afterwards to assure their full development.

I have not found that the removal of the oldest leaves is of benefit to the tuber, as it is mostly carried out at a period when the nutriment manufactured by the plant is commencing to accumulate in the tuber.

The Prague Giant variety is one that is less inclined to become brown in the flesh, and it is generally cultivated in Austria-Hungary for its long-keeping property. When Celeriac is removed from the land the tubers should be laid in light cellars or cold pits or frames, bedding them in fine soil to half their depth, a few inches apart, and affording water once to settle the soil about them. Before laying in, the chief leaves should be cut off close down to the tuber, the heart leaves only being preserved in order that a slight amount of growth may be maintained in the plants for several months.

In planting the Celeriac in the open air the 5 feet wide bed and the spaces between the plants of 1½ feet to 2 feet accordingly, as the variety is a moderate grower or a robust one, is preferable to long-row planting.

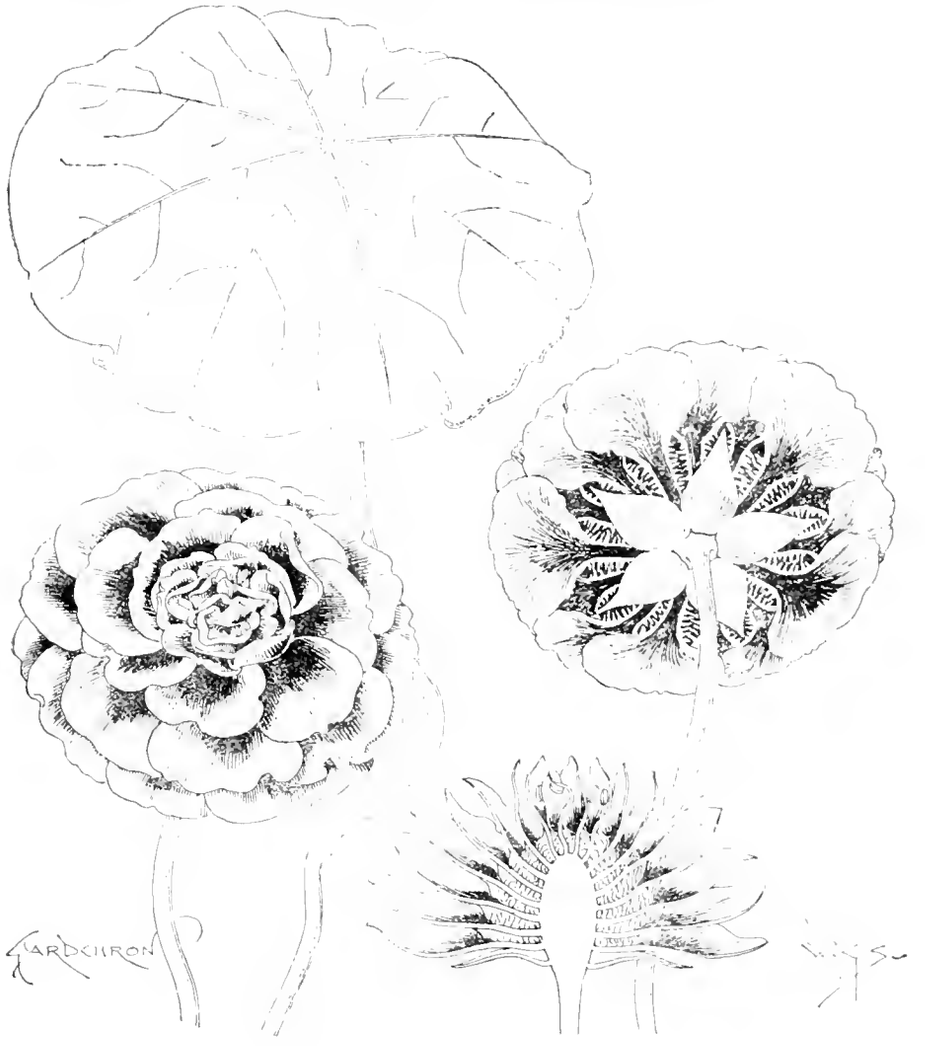

FIG. 140. TROPÆOLUM "DARMSTADT."

RAISING POTATOS FROM SEED.

THE sexual organs of the Potato flower are so arranged that they may be manipulated with ease. The essential organs consist of the five anthers, which form a cone, and the style or stigma which projects beyond the anthers that encircle it, but on reaching maturity the stigmas divide so as to expose their receptive surfaces. Select a truss of bloom on the plant intended for seed bearing and remove the anthers immediately the bloom opens, as by this process of emasculation the flowers are rendered incapable of self-fertilisation. By the aid of a lens the top of the stigma should be closely observed. In some flowers it will be found to be quite dry, and in others moist; the latter condition is when they are in a receptive stage. Pollen from the plant selected as the mate parent should be applied to the protruding stigma of the seed-bearing flower. A camel-hair brush is often used for this operation, but it is better to shake the ripe pollen on to a sheet of glass and to dust the stigma with this. The stem bearing the flowers thus treated should be carefully secured to a stake, and a label should be attached giving particulars of the date of pollinating and the parentage. Cover the whole truss with a piece of thin muslin to prevent the intrusion of insects that will, unless they are excluded, introduce foreign pollen. The muslin may be removed after a period of four or five days. The seed pods or "plums" should be allowed to remain on the plant for as long a period as is possible, but should the weather prove unfavourable to their ripening, and especially if the autumn is well advanced, the fruits should be taken off and hung up indoors to mature. When seeds are ripe, cut open the pods to extract them; they will be found to resemble not inferior Tomato seeds. They should be carefully dried and stored until the following spring, and then be sown in gentle heat. By the end of March or the beginning of April the seedlings should be ready for transplanting into larger boxes or pans, or, better still, singly in 60-pots. The seedlings should be ready for planting in the open in June, but no risk must be taken if the weather is unfavourable, for few plants are more susceptible to injury by frost than the Potato. *William Mallett.*

FLORISTS' FLOWERS.

AMERICAN AND OTHER TREE CARNATIONS.

WHEN the flowering season of these plants is past, it is not advisible to keep them in the glasshouse for the sake of a few flower-buds which may be unopened, as by this practice the cultivator will lose more than he gains, owing to the potting being delayed, and next season's flowering made later. If new stock is to be purchased, it is advisable to give the order to the nurseryman without delay. The purchase of rooted cuttings is not to be recommended, these being taken out of the propagating house once as they are very soft, and their roots are easily broken, so that many of them come to hand rootless. It is better to buy pricked-off cuttings, which bear transit and packing better, and soon make a good recovery. When the plants arrive, pot them without delay in light, sandy soil in small pots; keep them close and shaded from the sun, in a pit or garden frame having a temperature of 55°, and afford little moisture. As soon as new roots have begun to form, remove the shading gradually, and ventilate the structure freely. Unrooted cuttings should readily be procured by those who have had much experience in the propagation of Carnations. *E. M.*

TROPÆOLUM "FLORE PLENO DARMSTADT."

THE beautiful double-flowered Nasturtium represented in the accompanying illustration (fig. 140) was raised by Herr Henkel, of Darmstadt, and distributed by him last year. The flower is quite double and of an intense yellow colour, with scarlet feathering at the base of the petals. A more brilliantly coloured flower does not exist even among such a family as the Tropæolums. It has also the great merit of being exceedingly free-blooming, even in recently-rooted cuttings, and the flowers remain a long time in beauty. For covering a trellis during the summer season out of doors I do not know anything more brilliantly beautiful. I am indebted for the possession of this lovely plant to my friend, Mr. R. H. Beamish, who imported it last year direct from the raiser. It can be easily and quickly increased by cuttings, which make roots very readily, and when better known it will be seen in every good collection of ornamental flowering plants. *W. E. Gumbleton.*

BELGIAN HORTICULTURE.

MESSRS. SANDER & SONS, BRUGES AND ST. ALBANS.

THE establishment of Messrs. Sander & Sons at Bruges continues to extend. Block after block of plant houses, generally in several divisions, and extending 300 feet, have been added, and yet additions are contemplated, although the establishment in its present state employs over 100 hands. Kentia Palms occupy a large proportion of the houses, and visitors invariably ask what becomes of such an enormous stock? The answer is always the same. "No matter how many thousands we have, we never have enough and are continually running short of one size or another." And yet there are large numbers, apparently of every size, from the seedling just sprouting to the 12 feet high specimen.

Azaleas form another great culture with Messrs Sander, and it is very interesting to see in the different departments the process from striking the stock, to grafting it and developing the plants into specimens for sale. The fine display of flowers at the Bruges establishment, and at the Ghent show, well indicate the success attained in the raising of new varieties which is being done by Messrs. Sander, although this is no easy task, the already existing named varieties being so numerous and beautiful that it is very difficult to get new ones sufficiently distinct.

Camellias are grown in large quantities, and Messrs Sander have had great success in securing quite new types which we have seen in flower, though they will not be ready for distribution for several years to come. Camellia reticulata and its its white and double forms, all very difficult to propagate, are increased successfully. The stock of each can, however, never be great as the plants are of slow growth. Anthurium Scherzerianum with its showy scarlet, or mottled spathes; Bromeliads, with ornamental foliage and quaint flowers; stove and greenhouse plants such as Cordylines, Draccenas, Codiæums (Crotons), &c., (of which the bright green and yellow C. Fred. Sander is regarded as the acme of beauty in its class), Aralias, and some of the elegant smaller Palms occupy many houses, and all are in perfect condition.

In the open ground are a very large number of Bay trees in tubs, many of the specimens having large and finely formed heads; pyramids and standards are equally well represented, and in the standards a new feature is introduced by shaping some of them into conical heads instead of the globular form generally seen. Let the cultivator try how he may, it takes a long time to produce a really fine lot of Bays, and consequently the larger specimens secure proportionately high prices. Rhododendrons, Hardy Azaleas and other hardy market plants are grown in great quantities.

THE ORCHIDS

Ranges, apparently endless, of these plants were traversed during a recent visit to Bruges, some of the blocks containing quantities of Odontoglossum crispum for providing flowers for cutting and for market purposes. The Bruges establishment, rather than that at St. Albans, receives the freshly imported plants, and at present there are long ranges of houses filled with recently imported batches of Cattleya labiata, C. Schröderæ, C. Mossiæ, C. Mendelii, and C. Warscewiczii. Of the last-named species there was a singular illustration of the fine quality and floriferous character of C. Warscewiczii Sanderiana as compared with the original form, which was undoubtedly shy-flowering, both in its native habitat and under cultivation. The recently imported batch of C. Warscewiczii Sanderiana showed stout old flower spikes from nearly every growth, and the new growths are plentifully furnished with flower-sheaths. Some of each of the species named are in bloom, except the autumn-flowering C. labiata, and great variety is displayed in the blooms, especially of the C. Schroderæ, which ranges from blush-white with orange disc to the lip, to lilac with rich violet-purple labellum. Most of the showy species are in great quantities, such as Cattleya intermedia, C. Leopoldii, Lælia purpurata, Lælia-Cattleya elegans, L.-C. Schilleriana, and with all these kinds the demand for their flowers ensures a return for their cost and care, and the occasional fine variety supplies the profit.

Vanda cærulea of the very finest type is grown to perfection at Bruges, a long span-roofed house being filled with this species. The house is of cool, intermediate temperature, and the plants root freely, and as freely produce their spikes of sky-blue flowers. The contents of some of the other houses were Cypripedium bellatulum in large numbers, some very nice varieties being in bloom; C. Charlesworthii and the varieties of C. insigne, which are very profitable for supplying flowers for cutting; a house of hybrid Lælio-Cattleyas, Brasso-Cattleyas, Brasso-Lælia Digbyano-purpurata, Brasso-Cattleya Digbyano-Mossiæ, and

FIG. 141.—POLYSTICHUM FALCATUM VAR. MAYI.

others of that class; Lælio-Cattleya Baroness Schröder, L.-C. Dominiana of fine colour, varieties of L.-C. Myra, &c.

In one range is a fine lot of the scarlet Renanthera Imschootiana, Vanda Kimballiana, V. Parishii, V. Amesiana and V. Watsonii, in another V. Sanderiana, Aerides Houlletianum and other Aerides; Rhynchostylis retusa, a large batch of Dendrobium Phalænopsis, Cymbidium Lowianum, C. Sanderi and other Cymbidiums; Lycaste Skinneri of a very fine type; Ada aurantiaca, Cochlioda vulcanica, C. Noezliana, &c.

Specially noteworthy are the fine lot of Phalænopsis which thrive admirably. The best for all purposes on account of its free growth and the profusion with which it produces its large white flowers is that known as P. Rimestadtiana.

The block of houses set apart for the best types of Odontoglossum crispum have the innumerable specimens in fine condition. They are "grown cold," and with what some would regard as excessive ventilation, for the leaves are often stirred by the breeze. Some very good white forms of fine shape and substance are in bloom; several light rose-tinted varieties and a sprinkling of blotched flowers, of which were remarked a clear white O. crispum xanthotes with occasional deep orange spots, O. c. Thompsonii with deep purple blotching, and others.

One of the houses is devoted to the crossing and raising of Odontoglossums, and in it are a goodly number of plants with mature and bursting seed-capsules; and thousands of little seedling Odontoglossums in the earlier stages of growth.

In an adjoining house are a number of Odontoglossums raised at Bruges, a few of which are in flower, and a large proportion of the others in spike. Among those in flower is a very bright and distinct hybrid between O. crispum Thompsonii and O. Vuylstekei, and which is almost entirely of a glowing tint of chestnut-red with an orange shade, and tipped with white. This is not only handsome in itself, but should produce fine results for crossing.

Another pretty novelty is Odontoglossum Harryano-elegans with flowers equal in size to those of O. Harryano-crispum, but with rather narrower segments, as might be expected from the influence of O. elegans, which it resembles in the pretty purple spotting over the whole of the white, acuminate petals. Of the sepals, which are lanceolate, the upper one is the broadest; they are yellow, irregularly blotched with chocolate-purple, except on the tips and margin. The front of the lip is white, the base being spotted with violet.

All these seedling Odontoglossums have large bulbs and fine foliage, and evidently develop very rapidly under the treatment given them. *J.*

POLYSTICHUM FALCATUM VAR. MAYI.

At the meeting of the Royal Horticultural Society, held on April 14 last, Messrs. H. B. May & Sons, Edmonton, exhibited a new crested form of the Fern, known in gardens as Cyrtomium falcatum, but which is placed by Dr. Christensen in his *Index Filicum* under Polystichum. The plant has been the subject of change of nomenclature many times. It is placed by Hooker in his *Synopsis filicum* under Aspidium, and it has also been classed in other genera than those instanced.

Notwithstanding this confusion of names, the Fern is a valuable species for garden purposes, and there are few that surpass it for the decoration of dwelling rooms. The species is perfectly hardy in favoured parts of England, Wales, and Ireland, but when grown out of doors the leaves are shed in the winter. The plant, however, soon recovers when warmer weather prevails, and quickly develops a new crop of its handsome leaves. Besides the new variety "Mayi," there are many other forms and varieties of Polystichum falcatum.

AN ORCHID PARASITE.

Orchids imported from Brazil, chiefly Cattleyas, Lælias, and Sophronitis, very often have their leaves covered with small white spots, about one or two millimetres in size, due to the disappearance of chlorophyl at the place where punctures have been made by an insect. This parasite, Tenthecoris bicolor, belongs to the Hemipterous family of the Capsides. It may cause very serious damage, as I have seen in 1906 in the plant houses of the Parc de la Fête d'Or at Lyons. The continual punctures exhaust the plant, which decays and dies if remedies are not applied. The perfect insect, which is a fairly large one measuring 4 millimetres in length, lives underneath the leaves of the infested plant.

Its brilliant colouring of red and blue renders the insect easy of detection. It flies from plant to plant, and is very prolific in the plant houses. The larvæ also puncture the leaves of the plant and suck the juice upon which they live. All plants imported from Brazil should be washed with a brush charged with a good insecticide. If the insects should become established in the plant house, they may be eradicated by appropriate fumigations repeated each week for a month. The drawing (fig. 142) was made by my friend, Doctor Chobaut, of Avignon, from one of the insects caught in my hothouse about 11 years ago on one of the recently imported plants of Sophronitis. The following is a short description of the insect:—Tenthecoris bicolor, Scott, 1886, synonym Euritotarsus orchidearum, Reuter, 1902. Head, pronotum, and external edge of the upper wings of a pronounced brick-red colour; thorax and the rest of the upper wings bright blue; antennæ and legs yellow. The upper side of the body and antennæ covered with short, fine hairs. Head conical in front, with well-developed eyes. Antennæ more than half as long as the body. Pronotum constricted (*étranglé*) with a deep ridge in the centre of the constriction. The under part of the body is of a reddish-yellow. The length, excluding the antennæ, 4 millimetres, the breadth rather less than 2 millimetres.

Vanda cœrulea is often imported infested by a parasite allied to Tenthecoris, but its larvæ lives in the interior of the leaves, where it burrows out galleries. This latter insect is very probably a new one. I have only been able to secure specimens in poor condition, and I should be grateful to any readers of the *Gardeners' Chronicle* who may be able to kindly forward me some good specimens. *F. Denis, Balaruc les Bains, Hérault, France.*

THE ALPINE GARDEN.

THE SOLDANELLAS.

Among the choicest of the Alpine flowers which succeed in our climate are the Soldanellas, little gems of the Alps of Central Europe, which have few to surpass them in their delicate beauty in our gardens, and which merit and receive the unstinted admiration of those who take pleasure in the smaller flowers of the rock-garden. They may, indeed, be said to be ideal plants for the rock-garden, so neat are they in their growth, and so beautiful in their flowers.

That they are frequently unrepresented in collections of Alpines is not the fault of the plants themselves, but is due to the fact that many persons take little pains to meet their requirements, with the result that they are either shrivelled up by some dry and warm summer, or are found in a flowerless condition from year to year. These failures can easily be remedied, and there are some sound principles, which, if followed, will solve the difficulties which many have experienced with these Soldanellas.

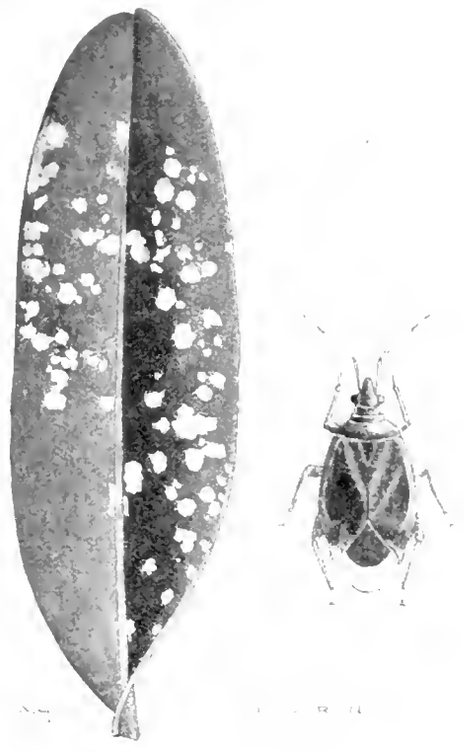

Fig. 142.—An orchid parasite. (Much magnified.)

In their native habitat the Soldanellas enjoy different conditions from those which prevail here, and it is the lack of these which is largely responsible for their failure in this country.

They like moisture in summer, but they abhor it above their heads in winter. At home they are shrouded in snow for a long period in winter, and in spring and summer they enjoy the water which flows from the same in melting; but in our gardens they are frequently planted on a dry rockery, and in winter are exposed to the rain, snow, and sleet, which, with too swift alternations, they have to encounter. The summer drought is disastrous to the health of the plant; the winter's changes are the cause of their non-flowering. Another cause of failure is the absence of a top-dressing.

The Soldanella should be given a moist soil, and in the drier parts of the country a position by the edge of a bog garden, but slightly above it, and with some stones packed about the crowns, will suit them splendidly.

In wet neighbourhoods they do not require so much moisture at their roots, and there they thrive best in a half-shaded place at the base of rockwork, but in a freely-drained soil, composed of peat, or leaf-soil, loam, and a little sand, water being occasionally applied in the shape of copious soakings, in continued dry weather only. A few stones placed about the plants will help to keep down drought. The contrast of plants which are thus accommodated and those which are perched on a ledge of a rockery, and are soon shrivelled up with summer sun, is great. Under the former conditions they develop crowns which flower, provided the precautions above-named are followed.

In order to induce regular flowering, there is nothing to equal the assistance of a piece of glass or a handlight raised a few inches above the plant, and put on from October until the flowering begins. It may, however, be allowed to remain until the flowering is past, but afterwards the sun is apt to become too strong, and the glass should be removed. I have experimented with this for some years, and have found the covering of the plant with glass an almost infallible factor in producing flowers. Some four or more species of Soldanella are in cultivation, and all are very beautiful and worth cultivating in gardens.

Soldanella alpina.—This, the Blue Alpine Moonwort, is a lovely plant, with roundish, rather kidney-shaped leaves, that are leathery in substance, and producing beautifully fimbriated bell-like flowers. These depend two or four together from a stem some 3 inches high, and appear about April. This species is one of the best of the genus, and there are a few varieties of it which differ but little from the type, although some are more floriferous than others. S. a. pyrolæfolia is one of the best varieties: S. a. alba has white flowers.

Soldanella minima.—The smallest Alpine Moonwort is a beautiful little plant, flowering about the same time as S. alpina, but producing flower-stems some 2 inches high only. Each bears one flower only; the blooms are cut to about a third of their length, and they are more spreading than those of S. alpina, while the colouring is pleasing, the flowers being suffused with lilac. If the interior is examined, it will be found to be striped with purple. The leaves are rounded, and the whole appearance of the plant is gem-like in its beauty.

Soldanella montana.—This is a favourite plant with many persons, with its purple blossoms, which are developed two to four on scapes 3 inches high; the petals are prettily cut to about the half of their length. The leaves of the Mountain Moonwort are almost round, with a few crenations at the margin.

Soldanella pusilla.—This is said by some authorities to be synonymous with S. Clusii, but there is some confusion on the subject, and it is to be feared that it will be difficult for the gardener to clear up this point. According to the *Kew Handlist of Herbaceous Plants*, S. Clusii of F. W. Schmidt is synonymous with S. montana var. hungarica, but it appears from other sources that S. Clusii of Gaudin is synonymous with S. pusilla, which is the one generally sold under this name. It is a lovely little plant, bearing from one to two bell-shaped blue flowers on the scape, these not being fringed, but only neatly notched around the margin. The blooms appear about April. This is a charming little Soldanella, and not at all difficult to cultivate. There is also a white variety of it.

Soldanella × hybrida.—This is said to be a natural hybrid between S. alpina and S. pusilla, and is apparently cultivated at Kew, but I have not come across it there, and cannot say anything about its features. It has been in commerce but at a high price, like another not in the Kew collection S. × Gauderi, a hybrid of S. alpina and S. minima. *S. Arnott.*

IN A FRUIT PLANTATION.

THE sudden rise in the temperature which took place on May Day caused such a burst of vegetation as is seldom witnessed. Never before have I seen fruit blossom come out so suddenly. At the end of one of the most wintry Aprils on record the expansion of blossom on fruit trees of every kind was extremely backward. Gooseberries, of course, were in full bloom before the end of the month, while Red Currants were about level with them, Black Currants being later to bloom than I have ever seen them before. The only Plum in my plantations in the extreme south of England in full blossom by April 30 was Black Diamond, while Monarch and Coe's Golden Drop were nearly or quite full on May 1. But by May 3 there had been so sudden an expansion that Early Rivers and Czar were fully out, while Victoria was nearly abreast with them, as also were Old Greengage, Denston's Superb Gage, and Oullin's Golden Gage.

Early-flowering Pears were in full blossom by May 3, and the buds of some later varieties were beginning to open. The only variety of Apple showing any considerable open blossom on that day was Irish Peach, though Beauty of Bath, Duchess of Oldenburg, and Early Julien were close behind it.

It is a curious fact that the blossoming of fruit trees and bushes in districts 100 miles to the north of my farm is earlier than it is here, probably because proximity to the sea and exposure to wind keep my fruit backward. This circumstance bears upon the question of damage from frost. Here we had 6° of frost on the night of April 20, measured 5 feet from the ground by an exposed thermometer. Everything was extremely dry then, and the few blossoms of Plums already expanded on exceptional trees did not appear to be harmed. A small number of my Gooseberries in the lower level of one field appear to have been touched, and some Red Currants in a small orchard, grown only for home use. But no considerable damage was done. The more severe frosts of the last week in April, 8° or more in many districts, did not trouble us here, as we had only 3° on one occasion, and we had comparatively little snow. The great damage to Gooseberries and Currants, and partial injury to Plums, reported from most fruit districts, we were fortunate enough to escape.

With respect to the shows of blossom, that of Plums is partial, some trees of a variety being fairly covered, while others are nearly bare. This is the case with Rivers' Early Prolific and Monarch. Victoria is more regular, there being about half a show, while Czar is fuller. Pond's Seedling has very little blossom, and Gisborne hardly any signs of it. Black Diamond and choice dessert varieties, except on a small lot of Coe's Golden Drop in a field, have only a sprinkling. Apart from possible damage hereafter, the Plum yield can hardly exceed half an average crop. Pears are about as densely covered with blossom as they could be, and Apples and Cherries are very well furnished. Gooseberries here promise well, but Black Currants, I fear, will be scarce.

Except where the tender shoots on the tops of Plum trees were banged about by the blizzard of the last week of April, the foliage and blossom of all kinds of fruit have a strikingly healthy appearance. Having been late in developing, there has not been any check to growth since the expansion of leaf and blossom. But aphis on Apples and Plums, and scab on Apples and Pears, will probably spoil this pleasing appearance. A search with a magnifying glass on several trees of nearly every variety of Apples grown, just after the trusses of blossom buds were fringed with spring leaves, led to the discovery of only one aphis, while not one was found among the Plums. Nor were any eggs noticed. Yet, in all probability, both Apple and Plum trees, as usual, will be smothered with the pest by the time that these remarks are in print. Last year there was a sudden and profuse infestation a few days after a search, in which only two or three aphides were found. Whence do they come? No one seems to know. I searched among some Myrobella Plums planted to thicken hedges, and among Blackthorns also, without finding a green fly. Some entomologists declare that the visitations of aphides always come from eggs on the trees, or from insects that have hybernated on them; but this in my case seems to be out of the question, as I have found neither eggs nor insects up to the present time. The aphis does more damage here than all other insects together, as, when once its attack has begun, the leaves curl around it, protecting it from spray.

There are no signs of the Apple sucker here at present, and it would be showing if it were in the plantations. Three years ago my Apple plantations were badly infested, but they have been clear in the last two seasons. Whether or not the pest was annihilated by summer or winter washes, or by the two in combination, is uncertain, but the fact remains that it disappeared, and there has been no reappearance. The Codlin moth does not trouble me, while leaf-eating caterpillars can be kept down by spraying, and the pith-moth maggot is relentlessly pursued year after year, and thus kept within moderate bounds.

Next to aphis, my great enemy is scab. As a preventive, the Apple and Pear trees were sprayed with a weak solution of copper sulphate alone, just before the fruit buds began to burst. After the blossom has fallen, they will have two sprayings of weak Bordeaux mixture—weak, because the ordinary strength scorches the foliage of some varieties. This treatment did good last season. Let us hope that the summer will not be as wet as the spring has been, so that there may be a chance of suppressing this damaging disease.

Mildew on Apple foliage has become more and more serious on some varieties in the last two seasons, and nothing has been found to be an effective cure but the plan of persistently cutting off and burning affected portions. Already it is showing on a shoot here and there.

To revert for a minute to the question of crops, there is one variety of Apple which is the exception to the rule as to a good outlook, and that is Charles Ross. I think my trees are six years from the budding, and they show hardly any signs of blossoming. The variety seems to be as slow in coming into bearing as Blenheim Pippin is, and the fruit is inferior in flavour to that of Peasgood's Nonsuch, the parent which it most resembles. In my opinion, Charles Ross is a spoilt Peasgood—less prolific, and of inferior flavour. It would be interesting to learn whether the experience of other growers in relation to it is the same as mine. My trees were raised by budding from one of the first lot sent out. The trees are fairly sturdy, and particularly shapely, and this is all that can be said in their favour at present. Possibly they may bear well in course of time. *A Working Grower.*

NEW INVENTIONS.

A TELESCOPIC PLANT SUPPORT.

SEVERAL devices for the supporting of plants have recently been placed before the public; particulars of the latest have been sent us by Messrs. Smith, Fletcher and Co., 172, High Street, Edinburgh. This support has an iron prong, with a sheath for inserting into the ground, and into this sheath the stand slides, thus enabling it to be raised as the plant increases in height. A small pin passes through the sheath and through the support, which is pierced with several holes, thus enabling it to be raised or lowered.

The Week's Work.

THE FLOWER GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

Summer bedding.—Tastes in regard to the planting of the flower garden are very dissimilar, but in all cases it is necessary to consider harmony and contrast in respect to colour. For example, an oblong bed planted with standard Heliotropiums, and having a groundwork of the new dwarf variety of the scarlet Salvia splendens known as Pride of Zurich, may be described as planting for the purpose of contrasting the colours. This variety of Salvia is very compact in habit, free flowering, and early. It does not grow more than 12 inches in height, has erect spikes of bloom, and produces early in June a quantity of the most brilliant scarlet flowers. It may also be expected to continue in flower until autumn. For an instance: in the harmonising of colours, a bed in the form of cross keys planted with Calceolaria amplexicaulis of soft yellow colour, with a groundwork of Salvia Pride of Zurich, would be pleasing. The Calceolarias should consist of plants taken from 6-inch pots, being specimens 5 to 6 feet in height, having large heads yet being lightly branched up the stems, and they should be planted about 2 feet apart each way. Salvia Horminum grandiflorum violacea, with bright violet-coloured heads interspersed with Galtonia (Hyacinthus) candicans and Tuberoses planted in a diamond-shaped bed, was pretty. Beds which are crowded together in geometrical designs are not suited for this type of planting. The three beds I have mentioned stand apart from each other, and have double Box edgings, filled in with white marbled chippings upon gravel. A noble-looking bed, if cut out of the grass and made sufficiently large to give a good effect, is one planted with Nicotiana sylvestris, having large, sweet-scented, pure white flowers, intermixed with Ricinus Gibsonii, which has dark stems and foliage. A border measuring 60 yards in length and from 3 to 4 feet in width planted in the following manner was admired by many:—A excellent strain of Antirrhinums containing a good proportion of salmon-rose or coral-red varieties was planted, and the dwarf-growing plants were intermixed with those of a taller habit. A similar border planted with Dianthus Heidewigii in numerous shades of colour mixed with patches in distinct colours of such varieties as Salmon Queen, Diadem, Queen of Holland, and The Bride, at regular distances, and dotted with standard plants of Iresine Herbstii, I. Lindenii, and Veronica Andersonii, with a background of Pelargonium "Madame Crousse" in tubs, and Agapanthus umbellatus, was effective.

Herbaceous borders.—Such plants as Delphiniums, Pæonies, Aconitums, and Sweet Peas should have stakes put to them before the growths fall over and become deformed.

Roses against walls.—These plants should now be treated with some approved insecticide, such as quassia extract.

Garden paths.—Choose a dry day and apply a dressing of some weed killer to the garden paths, but do not let the mixture be applied within a distance of 6 inches from the edges of grass or Box.

PLANTS UNDER GLASS.

By THOMAS LUNT, Gardener to A. STIRLING, Esq., Keir, Perthshire, N.B.

Acacia Riceana.—This species is now passing out of bloom and should be re-potted into a compost consisting of loam, leaf-mould, and sand. Place the plants afterwards in a position where they will be fully exposed to the light. The plants would succeed very much better if planted out in a border where the roots would have plenty of room to extend. The shoots may be trained up the rafters under the roof of the house, so that they may afterwards droop from the roof, and thus display their flowers to the best advantage.

Lapageria alba and L. rosea.—These plants are now growing freely, and care should be taken to see that the shoots do not get twisted together. If the plants are trained on a balloon-shaped trellis, the young shoots should at first be trained on single strings tied out to stakes extending from the balloon, and after the shoots

have become well-ripened and flower buds are appearing, the strings may be cut away and the shoots trained evenly over the balloon. Apply weak liquid manure to the roots at frequent intervals, and syringe the plants each day. Lapagerias succeed excellently when cultivated in a border and their growths trained up the roof of the greenhouse, from which they may be allowed to hang loosely. When thus grown in a border, slugs are very destructive to the young shoots as these latter emerge from the soil. I have found it to be a good practice to keep a sharp look-out for these shoots, and directly they emerge from the soil to cover them with glass bottles from which the necks have been knocked off.

Chorizema Lowii.—This species is now growing freely, and if the plants are found to require larger pots the re-potting may be undertaken at once. A compost of peat and sand, with a few pieces of charcoal, will be suitable. This species being of a very free-growing habit requires plenty of root-room, and the soil should be made only moderately firm. The shoots should always be trained so that they will incline slightly upwards, for if this is not done they will die back to the position of a shoot which does point in an upward direction. Much care is needed in tieing in the shoots, and if they have been allowed to get hard they will be likely to break off at the joint, for when thoroughly ripened they are very brittle. If cultivated in the same house as Azaleas, and given similar treatment, the plants will succeed. Propagation may be effected at the present time by inserting cuttings prepared from the young unmatured shoots. Insert them in a compost of peat and sand only, making this compost very firm about each cutting. Place the pots in a brisk heat and keep the atmosphere close until the cuttings have made roots.

Rhododendron (Azalea) indicum.—Plants that are growing freely and have their pots well filled with roots should be given slight sprinklings of Peruvian guano at intervals of three weeks, until it is seen that the flower buds are formed for next season. Syringe the plants twice each day during favourable weather. Maintain a moist atmosphere and shade the plants from fierce sunshine.

Brunfelsia (Franciscea) calycina major.—As soon as these plants have flowered they should be re-potted into a compost consisting of loam two parts, leaf-mould one part, and peat and sand one part. Place them in a house having an intermediate temperature and syringe the plants frequently. Any plants which will not be re-potted should be given applications of liquid manure. As soon as the plants have completed their growth remove them into a cool house where they may rest until next spring. If this species is flowered in the atmosphere of the greenhouse the blooms develop a much deeper colour and have better lasting properties than is the case when they are developed in a greater degree of heat.

FRUITS UNDER GLASS.

By T. COOMBER, Gardener to LORD LLANGATTOCK, The Hendre, Monmouthshire.

Fig trees in pots.—If the trees are expected to ripen a second crop of fruits, every encouragement should be afforded them directly the first crop has been gathered. It would, however, be better not to obtain a second crop if it is intended to force the trees again early next season. In any case, the second crop should be only a moderate one. Take measures to cleanse the trees of any insect pests that may infest them. Afterwards remove the top-dressing from the pots and afford a fresh top-dressing consisting of loam and crushed mortar rubble, with a little concentrated manure added. On no account allow the roots to suffer from drought even for a short period. Apply occasional waterings of diluted liquid manure. Keep the growths regularly stopped. Ventilate the house freely, and syringe the trees thoroughly at least twice each day during fine weather.

Fig trees in borders.—These trees having been started early enough to yield successional crops to those Figs cultivated in pots, will now be swelling their fruits, and therefore the roots should be given applications of liquid manure. It will be necessary to keep the atmosphere rather drier than formerly as soon as it is seen that the fruits have commenced to ripen. Afford increased ventilation during the day, and a little ventilation during the night. Let each fruit be exposed to the rays of the sun as much as possible. Later trees in separate houses should have their shoots thinned out and pinched, so that the leaves will not overcrowd each other. By attending to the pinching of the shoots at intervals of a few days and continuing this practice for as long a time as practicable, the ripening season may be thereby prolonged. Ventilate the houses freely, especially when the sun is powerful, taking care to prevent the leaves suffering injury from scalding. Syringe the trees thoroughly each day, maintaining a moist atmosphere. Remove all suckers from young trees, and thin out the shoots sufficiently to enable those which are selected for forming the tree to grow sturdily and firm.

Planting vines.—Young vines raised from eyes early in the present year may be planted at any time during the next few weeks. Plants of this description should be planted in borders wholly contained in the house, but an outside border may be added thereto at a subsequent period if it is considered desirable. If borders have been made according to the directions printed in the Calendar in the issue of this journal for February 1, and a sufficient length of time has elapsed for the soil to become warm, such borders will now be in a suitable condition for planting. If the young vines have been so far cultivated upon turves instead of in pots, their planting will consist simply in placing them in position on the border and carefully covering the roots with a warm, turfy compost, or in making shallow holes in the border for the reception of the turves. But if the vines are in pots, turn out the roots carefully, remove the crocks and firmly plant the roots in some specially prepared compost. Complete the operation by applying a light mulch of short horse manure and a watering with tepid water. If the vines have to be procured from a distance, allow them sufficient time to recover from any ill effects they may have received during transit before subjecting them to the check caused by planting. Permanent vines should be planted at distances of 4 to 6 feet apart, with supernumaries ("cut backs" being best for this purpose) planted between each pair for providing immediate crops.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree, Hertfordshire.

Celery.—There is no more important kitchen garden crop than Celery, neither is there any crop that responds more readily to good cultivation. Indifferently grown Celery is of little value, therefore cultivators should do all that is possible to obtain the most perfect crop. In the first place it is essential to cultivate the best varieties, and afterwards it is necessary to take every care to prevent the plants suffering any check during the whole season of their growth. Directly the plants which have already been pricked out are ready for transplanting to the trenches, which have been prepared in the open gardens, let them be removed to this position. If these trenches were prepared according to the directions I have previously given, the soil is likely to be in a good workable condition. In order to obtain a continuing supply from August until April, several plantings are necessary, but in all cases where it is possible, the trenches should be taken out and prepared several weeks previous to planting. There is no advantage to be gained by putting the plants at a great distance from the surface of the ground, but, on the contrary, it is detrimental to plant them at such a depth in gardens where the soil is of a heavy and tenacious character. In such cases, the plants should be kept as near the ground level as possible, allowing only sufficient space for the reception of water. Make the soil about each plant very firm, and apply a dusting of fresh soot during the evening or early in the morning once a week. Do not allow the Celery plants at any time to suffer from drought. Lettuces in various stages may be cultivated on the ridges of soil between the rows of Celery.

Celeriac or Turnip-rooted Celery.—To ensure good specimens of the Turnip-rooted Celery, strong plants should be put out at the present time into deeply-tilled, rich ground, preferably on a border facing to the south. Allow a distance of 2 feet between the rows and 18 inches between each plant. During the season of growth it is difficult to apply more water than is needful for this crop, and liquid manure containing a little soot should be frequently given.

Brussels Sprouts.—Plants raised from the earliest sowings under glass, which were duly pricked out, should now be ready for planting into their permanent quarters. Choose a well exposed piece of ground which was prepared during the winter. Lift the plants with as much soil adhering to the roots as possible. Use a garden trowel in the process of planting, and make the soil very firm. As a preventive against slugs, place a good handful of finely-sifted cinder ashes around the stem of each plant.

Turnips.—The earliest plants are looking very well. Attend to the thinning out whilst the plants are still quite small. Frequently stir the surface soil and apply a dusting of soot at intervals of ten days. Make small sowings at frequent intervals to maintain a supply. Desirable varieties for sowing at this season include Snowball, Jersey Lily and Red Globe.

Carrots.—Make a liberal sowing on a south or west border, choosing varieties of the intermediate and stump-rooted types. Attend to the thinning out of earlier batches and sprinkle soot and wood ashes liberally between the rows. If green fly appears, syringe the plants with quassia extract or dust them with tobacco-powder.

THE HARDY FRUIT GARDEN.

By F. JORDAN, Gardener to The DOWAGER LADY NUNBURNHOLME, Warter Priory, Yorkshire.

Peach blister.—This disease is generally known to be brought about by north and east winds, and this being the case, it is likely to be more than usually prevalent this season. It may be guarded against in some measure by using protective material over the trees during the presence of such winds. I have tried many so-called remedies, but none has proved either a cure or preventive, and the best thing to be done therefore when the disease is present is to divest the trees of any curled leaves and the shoots bearing them, removing them at once to the fire. Cultivators, however, may be recommended to try the specific known as "Medela," which is highly recommended for use during the season when the trees are dormant. At the same time, every attention should be given to such matters as root-pruning, watering, and the training of the shoots thinly so as to do all that is possible to induce the shoots to become thoroughly ripened each season (see also note by Mr. Fife in the *Gardeners' Chronicle* for February 15 last).

Apples and Pears.—The Apple blossom weevil (Anthonomus pomorum) is one of the worst pests that infest Apple trees. The larvæ or caterpillars destroy the blossoms before they expand, and they afterwards feed upon the young leaves. Sprayings during winter are the best means of combating this pest, but at this season of the year means must be taken to destroy any grubs already contained in the flower-buds, and their presence may be detected by the petals rolling up and turning brown. The caterpillar of the winter moth (Cheimatobia brumata) also feeds upon the young leaves and flowers, and a strict watch should be kept for these.

The Pear midge (Diplosis pyrivora).—The female midge deposits its eggs on the Pear blossoms, and the fruits become deformed and fall to the ground, containing as a rule one or more caterpillars. Such fruits should be gathered together and burned without delay. Trees that are subject to attack from Pear midge should be sprayed every winter without exception, for sprayings applied during the growing season are of little avail. The only effective remedy then being to pick the caterpillars off the trees by hand. Apply a dressing of kainit to the ground during winter.

Apricots, Cherries and Plums.—Examine the trees for any pests which are destructive to the foliage. Quassia extract is a good and cheap insecticide, and may be most economically used as a preventive before the foliage becomes curled. If this is delayed until an attack is present, it will be necessary to remove all the curled leaves and caterpillars and syringe the trees with Richard's XL-All insecticide. In this case the trees should be thoroughly washed on the following morning with clear water applied by means of the garden engine.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, MAY 16—German Gard. Soc. meet.

TUESDAY, MAY 19—
Devon County Agric. Sh. at Plymouth (3 days).

WEDNESDAY, MAY 20—
Roy. Bot. Soc. Exh. at Regent's Park.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—53.9°.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, May 13* (6 P.M.): Max. 62°; Min. 47°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, May 14* (10 A.M.): Bar. 29.6; Temp. 55°; Weather—Raining.
PROVINCES.—*Wednesday May 13* (6 P.M.): Max. 52° Colchester; Min 47° Scotland N.

SALES FOR THE ENSUING WEEK.

WEDNESDAY—
Bedding Plants, Bulbs, Palms, Rhododendrons, Conifers, Ferns, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.

THURSDAY AND FRIDAY—
Clearance of large quantities of Palms, Ferns, Orchids, Carnations, Azaleas, &c., by order of Messrs. Heath & Son, at the Royal Exotic Nurseries, Cheltenham, by Protheroe & Morris, at 12.

FRIDAY—
Choice Imported and Established Orchids in large variety, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

Artificial Production of New Species.

Professor MacDougal, who has been for some years engaged upon the problem of the artificial production of new species of plants by injecting various salts into the ovaries of the flower, claims to have obtained novelties in several genera. The most notable one is a form derived from Œnothera biennis, which he calls "F. 206," in which the new plant has remained true for several generations. It is easily distinguished from the parent species, and, furthermore, does not readily hybridise with it. Experiments are in progress on the effects of calcium nitrate, zinc sulphate, methyl blue, in various strengths of solution, on a considerable list of plants, e.g., Cereus, Nicotiana, and Pentstemon. Of course, the failures are numerous; that is only to be expected, not only on the grounds of the difficulties of manipulation, but also because the organism might altogether fail to respond to the substances used. The point of view from which the work is being carried on may be most easily grasped by the following quotation from a lecture delivered a few months ago in Chicago by Professor MacDougal: "The forms and qualities exhibited by organisms represent the total effect of environment, but it cannot be shown that this has been brought about by direct adaptation; many of the most highly specialised and useful structures bear only an indirect relation to the factors to which they bear a useful relation. Neither has it been demonstrated that an individual adjustment made by the soma is impressed upon the germ-plasm, and transmitted unchanged. . . . Various agencies experimentally applied in such manner as to affect the germ-plasm only have caused the origin of forms bearing fully transmissible qualities not presented by the parental type. The new characters have been found to be fully heritable, and the induced forms do not always hybridise with the older types. The induction of such new forms in plants may be accomplished by re-agents applied to the generative nuclei carried by the pollen-tube, and probably by action on the embryo-sac, in the period following reduction division. Mutations have been taken, on hypothetical grounds, to be based on changes occurring previous to these divisions. The various agencies used in inducing new forms in this manner may have a stimulating effect, or may cause direct disturbances in the chemical balance of the substances in the chromatin and plasma. [Substances found in the cell.] Similar action may result from unusual intensities of various environmental conditions, or to accidental intrusions on germ-plasm of many kinds. The alterations in question may well lie beyond detection by cytological, or by any direct method of examination. When the nature of the induced changes is once ascertained, the inductive agents might be applied in such manner as to guide the course of development and thus actually control the evolution of organisms. By such methods, man, the conscious organism, might assume a dominating rôle in the world of organisms and create relations among living things not now existent."

If further research should substantiate the claims made by Professor MacDougal, it will readily be seen that a powerful instrument is within our reach for inducing variation. But it must be clearly understood that the variations are likely, if producible at all, to be empirical. There can hardly be any question of "adaptation." What will have been effected is an alteration of those chemical processes which finds expression in the particular character of any individual plant, and if we can really alter these we shall at the same time doubtless modify the whole organism. For this chemical machinery, germ-plasm, physical basis of inheritance, or by whatever other name we call it, is the really important thing. If once this can be got at and changed, then variation must inevitably follow, and if the change were permanent in its character, the corresponding variation may also be expected to be stable. But it will be wise not to expect too much, at any rate, for some time to come. Even if it should turn out to be possible to induce variation in this way at all, it of course does not follow that the new forms would be improvements upon the old. In the world around us we see variation enough brought about by natural causes, as we say, but the real advances, from the economic or aesthetic point of view, are few enough. In stimulating the formation of new varieties, as now practised, we have the advantage of dealing with processes such as crossing, the rules governing the results of which are gradually becoming better appreciated. Whether a similar outcome is to be anticipated from injection methods still remains to be seen.

Some doubt may perhaps be legitimately felt as to the correctness of the interpretation of the change which has been found to occur in the case of the plants experimented on. We know already that Œnothera Lamarckiana is constantly throwing off more or less stable variations, and Œ. biennis is closely related to it. May it not be possible that natural variation may have occurred in the experimental plots, and have been mistaken for an artificially-induced one? Criticism is, however, premature at the present time. The future will soon show how far the new variations are the result of natural conditions, and how far they are to be attributed to the effects of a direct action of the substances employed upon the germ-plasm of the species.

OUR SUPPLEMENTARY ILLUSTRATION.—Of the numerous Japanese Lilies flowering in British gardens none are more delicately coloured than the flowers of Lilium japonicum (syn. L. Krameri). In the winter of 1871-72 coloured drawings of three beautiful forms of this Lily were received by the late Dr. WALLACE, of Colchester, from his collector, Mr. KRAMER, in Japan. Varying so much in colour the suggestion was at once made that it was a hybrid, and the species L. japonicum × L. auratum, or L. japonica × L. speciosum, were mentioned as the probable parents. Under the name of L. Krameri, Hook., the rose-tinted form is figured in the *Botanical Magazine*, tab. 6058. Subsequent investigation proved this plant to be identical with L. japonicum, Thunb., a species found growing in abundance in Southern Japan. The bulbs are small, 1 inch to 2 inches in diameter, the stem 1 foot to 3 feet high, rarely 4 feet; leaves scattered linear-lanceolate, 5 inches to 6 inches long; flowers variable from white to deep mauve, scented, 1 to 4 on a stem, sometimes 5. In the *Gardeners' Chronicle*, August 11, 1877, Mr. J. H. KRELAGE, of Haarlem, mentions having flowered a purple variety amongst a recent importation. No great degree of success has attended the cultivation of this Lily in our gardens, and were it not for a plentiful supply of imported Japanese bulbs this beautiful member of the genus Lilium would be very rare. The late Mr. WILSON in his garden at Wisley, now the home of the Royal Horticultural Society, grew it successfully in a bed of Rhododendrons. The most suitable soil is an open compost of peat and sandy loam. Imported bulbs flower well in the first, and sometimes the second year. They should be laid on soil in a frame, and started into growth previous to planting them out of doors, taking care not to over-water the plants until they are well rooted. It would be worth while trying to establish this Lily in our gardens by raising plants from seeds, it being just possible that seedlings raised in this country would be more amenable to cultivation.

MEMORIAL TO SIR THOMAS HANBURY, K.C.V.O.—On Sunday, May 3, a bronze bust of Commendatore Sir THOMAS HANBURY, K.C.V.O., was unveiled at La Mortola in the village square. There was a representative gathering of thousands of people from the neighbouring towns and villages. The Government was represented by the SOUSPRÉFET of SAN REMO and the MAYOR of VENTIMIGLIA. After the inaugural speech by Mr. ALWIN BERGER, curator of the garden, the bust was unveiled and the English National Anthem was played by the Ventimiglia municipal band. The MAYOR of VENTIMIGLIA spoke in high terms of Sir THOMAS HANBURY, and acknowledged the good the community owed to Sir THOMAS HANBURY's kindness. The SOUSPRÉFET and PROF. CALVINO, from Porto Maurizio, also paid eloquent tribute to the memory of Sir THOMAS, and CECIL HANBURY, Esq., returned thanks in the name of his family. The cost of the bust was defrayed by subscriptions from the Mortola population.

THE BOTANICAL MAGAZINE.—The current number of this periodical contains figures and descriptions of the following plants:—

TILLANDSIA BLOKII, tab. 8192.—The origin of this fine plant is not known, but it seems to have been regarded as a form of T. regina. It was shown under the name of T. Blokii at the Ghent Quinquennial Exhibition in 1898, and the specimen was then described in the *Gardeners' Chronicle* as being "as tall as a man." The specimen from which the illustration in the *Magazine* was taken, was grown by Mr. F. W. MOORE, who purchased it in 1903 as a seedling of the original plant shown at Ghent.

PHILADELPHUS × PURPUREO-MACULATUS, tab. 8193.—This plant is stated by LEMOINE to have arisen from P. Lemoinei "fantasie," a hybrid of which P. Coulteri was one of the parents. It is a beautiful plant with a purple red blotch at the base of each petal. It is said to be hardy and easily propagated by cuttings, which, when made of young shoots and placed in a brisk bottom heat, readily strike root. In cultivation the shoots that have flowered should be cut away after the blossoms are over, the young growths which are thus stimulated forming the flowering shoots for the following year.

PUYA VIOLACEA, tab. 8194.—A Bromeliad with stiff, linear leaves about 20 inches long. The flowers have green sepals and deep violet petals. The plant requires dry, sunny conditions, such as suit Cacti and Agaves.

LIPARIS TABULARIS, tab. 8195.—This handsome orchid probably came from Penang, and was sent to England by Mr. C. CURTIS, of the Forest Department, Penang. It is closely allied to L. macrantha, differing from it in the orbicular lip. The flowers are large and of a reddish-purple colour.

PRUNUS TOMENTOSA, tab. 8196.—Figures of this plant, representing flowering and fruiting sprays, were published in our last issue, on pp. 296, 297.

A NEW VARIETY OF CAMPANULA. M. MAX GARNIER, writing in the *Revue Horticole*, describes a dwarf variety of Campanula glomerata, which seems likely to prove a good rock plant. The plant forms sessile rosettes, from which rise dense clusters of violet-blue flowers, borne on stems about 3 or 4 inches in height. The plant flowers in June and July, and in favourable seasons bears another crop of flowers in the autumn.

PEA NUTS IN AMERICA.—The Pea or Monkey nut is the fruit of a leguminous plant, and it is said to grow wherever the Indian Corn will flourish. A writer from Kansas gives an account of the cultivation of these nuts in a recent number of the *Garden Magazine* (New York). The nuts are planted by hand in well-worked soil early in May, and plenty of room is given for each plant to develop. After the flowers have set, the fruits bury themselves in the ground, and they are dug up with a Potato fork as soon as the first killing autumn frosts begin. After drying, the nuts are shaken from the trailing branches with light sticks.

UDO, A JAPANESE SALAD PLANT.—In a lecture on the work of the Department of Agriculture in America, Dr. DAVID FAIRCHILD mentions, under the above name, a vegetable that is in much favour in Japan and also now in America, as a salad plant. It is described as forming a welcome change from Lettuce and other salad plants, and the thick shoots, the blanched portions of which are 2 feet long or more, are shaved into thin strips and served with French salad dressing. It is said to possess a distinct and agreeable flavour, and a pleasant crispness. It succeeds well in the experimental grounds at Washington and proves a heavy yielder.

"THE JOURNAL OF THE BOARD OF AGRICULTURE."—The fifteenth volume of the *Journal of the Board of Agriculture* begins with the issue for April, 1908, and arrangements have been made for the introduction of several new features. In the first place, the size of the *Journal* will be increased from 64 pages to 80 pages each month. The additional space will be filled with a monthly article on the course of trade in agricultural produce during the past month, and a comment on the tables of prices that are printed at the end of each number. An attempt will also be made to print from time to time reports on the condition of crops abroad, especially on the Continent, and on the trade in those articles of agricultural produce which compete with home-grown produce. In the April number two other series of articles will be begun, the first on weeds, fungi, and agricultural pests, illustrated each month with a coloured plate, the other, on the agriculture of small holdings, showing what methods have been adopted by those who have been successful, with suggestions for those who are about to take up new holdings. As it is intended that these articles shall be of service to all classes of agriculturists, the price of the *Journal* will not be raised, but it will continue to be issued at 4d. per monthly number. A valuable article on manure is contributed by Mr. A. D. HALL, Director of the Rothamsted Experimental Station, in which he shows how farmyard manure deteriorates under the ordinary conditions under which it is stored. Seeing how important an adjunct to proper cultition this material is, one can only be surprised at the way its value is almost thrown away in many cases by those whose pockets it ought to help to enrich. Comparatively few people realise how widely the manure of animals under different conditions of feeding varies in value, and we have ourselves known many instances where prices quite out of proportion to value received have been paid. It is, of course, generally recognised that cake feeding improves the land, so much so that an allowance for expenditure on this item is very generally allowed to an outgoing tenant farmer. But the market gardener who uses manure is often not nearly careful enough to ascertain the conditions under which it is made, and when he buys it, not seldom follows the bad example set by many farmers, and through ignorance, allows it to very seriously deteriorate. Mr. HALL'S article ought to be read by those who use manure for the garden no less than by those who require it for the farm.

AN AMERICAN FROST ALARM CLOCK.—An inventor at Kennewick, Wash., has produced what is termed a "frost killer" for orchardists. The device is a combination of an alarm clock and a thermometer. On the approach of frost the thermometer registers and sets off the alarm, which is placed in the house. Tanks of crude oil are kept in the orchard, 40 to 60 small cans being required to the acre. When the alarm is given the orchardist goes to his oil cans and starts them burning, and the temperature of the atmosphere surrounding the trees is raised from 2° to 6°, making the threatened danger nothing to be feared. *American Florist.*

BANANAS IN BARBADOS.—It appears that the Banana industry, which seemed so full of promise a few years ago in Barbados, has almost disappeared owing to difficulties connected with shipping the produce. It has been stated that there are some 5,000 acres of good land in the island capable of producing Bananas at a profit, and all that is needed is the possibility of getting them properly exported. The Barbados fruit is of good quality, and its cultivation might well take its proper place beside that of cotton and sugar.

PERPETUAL-FLOWERING CARNATIONS.—We have received a little treatise on *The Cultivation of the Tree or Perpetual Flowering Carnation*, by Mr. C. H. TAUDEVIN, and published by Messrs. YOUNG & CO., Hatherley, Cheltenham. The treatise contains a few simple directions on the propagation, potting, stopping of the shoots, housing, disbudding, and manuring of these plants. The remaining pages consist of a calendar of operations, in which the details of the work are given under each month. The pamphlet contains 24 pages, and the published price is 1s.

TESTIMONIAL TO MONS. FRED. BURVENICH.—On October 12 last M. FRED. BURVENICH was appointed for the fiftieth time principal of the classes on arboriculture and vegetable culture at the Ghent School of Horticulture. To mark the occasion of this event, a number of his colleagues, former pupils and friends have decided to present him with a testimonial. Thanks to the teaching of this venerable master, many of his old students now occupy honourable and lucrative positions, or have become important cultivators of trees and plants on their own account. There is no one in Ghent who, for fifty years, has given such a regular course of instruction in this subject as M. BURVENICH, and he has also lectured at Courtrai, Roulers, Lokeren, St. Nicolas, Eecloo, Alost, Ninove, and in many other agricultural centres. M. BURVENICH has also earned for himself great praise by the activity he has displayed as an horticulturist. He is the author of a work on arboriculture in the Flemish language which has seen its tenth edition. His book on the subject of vegetable culture, published in the two languages of the country, has reached its fifth edition. Several editions of other works of his have been published, and all the numerous books are ample testimony to the indefatigable activity of their author. M. BURVENICH was the founder and one of the principal members of the staff of the *Revue de l'Horticulture Belge et Etrangère* and of *Bulletins d'Arboriculture* (from 1864), and in the last years of their existence he edited these bulletins. The committee in charge of the testimonial consists of over a hundred members, the hon. president of which is M. BRAFFORD, Directeur-Général au Ministère de l'Agriculture, with M. A. COLUMBIEN as president, and M. LEON DE LOOF as secretary and treasurer. To many Englishmen Mons. BURVENICH will be known in connection with the Ghent Quinquennial Exhibitions, and no greater testimony to his skill as a landscape gardener could be offered than the scenic effects obtained in the annexe at the exhibition so recently held in that city, the designs of which were those of M. BURVENICH. Subscriptions may be sent to either of the gentlemen mentioned above or to the assistant secretary, Mons. E. SLEEWAEGEN, Rue d'Argile, Gentbrugge.

LIZARDS AS INSECT EXTERMINATORS.—In Georgia fruit-growers buy lizards in large quantities and turn them loose in their orchards. These lizards are the especial foes of the short-horned grasshoppers, a common farm pest. Examinations of the stomachs of dozens of lizards at the State zoological laboratory shows their diet to have been composed entirely of grasshoppers, beetles and other destructive insects. *American Florist.*

FLOWER SHOW AT THE FRANCO-BRITISH EXHIBITION ABANDONED.—We are informed that owing to arrangements that it has been necessary to make in connection with the opening of the exhibition and the visit of HIS MAJESTY THE KING and the President of the French Republic, the Executive Committee of the Franco-British Exhibition have been reluctantly compelled to abandon the Horticultural Show, which was to have been held on May 19 and 20.

FLOWER SHOWS AT BIRMINGHAM.—The Birmingham Botanical and Horticultural Society have decided to again hold two extra flower shows as in 1906 and 1907. They will be held at the Botanical Gardens, Edgbaston, on June 11 (Orchids and early-summer flowers) and July 15 (Roses and midsummer flowers). Honorary exhibits of flowers, fruits, and other products will be welcomed. Schedules may be obtained from the hon. secretaries at the Botanical Gardens, Birmingham.

POLYANTHUS "BRONWYLFA."—At the exhibition of the National Auricula and Primula Society held in the Royal Horticultural Hall on April 28, this variety of yellow-flowered Polyanthus was granted a First-Class Certificate. It was shown by Mr. W. A. WATTS, Bronwylfa, St. Asaph, who was a successful exhibitor in the competitive classes for Polyanthuses.

Publications Received.—*Country Queries and Notes.* No. 1, Vol. I. (April). This is a new monthly journal, and is stated by its promoters to be for the interchange of knowledge and ideas between students of nature and lovers of country life. Published at the price of 4d. per copy.—*The Summer Garden of Pleasure*, by Mrs. Stephen Batson, with 36 illustrations in colour by Osmund Pittman. (London: Messrs. Methuen & Co., 36, Essex Street, W.C.) Price 15s.—*Vegetables for Home and Exhibition*, by E. Beckett. (London: Messrs. Simpkin, Marshall, Hamilton, Kent & Co., Ltd.) Price 5s.

NOTICES OF BOOKS.

* "DAHLIAS AND THEIR CULTIVATION."

CULTIVATORS will be likely to welcome this brightly-written book on the Dahlia. It contains chapters on the evolution of the Dahlia, propagation of the plants for exhibition, potting and re-potting, preparation of the ground out-of-doors, also information upon the matters of watering, training, feeding, protecting the flowers, staging the flowers, and judging. Part 2 is devoted to the culture of Dahlias for garden decoration exclusively, and will therefore be useful to the numerous cultivators of the Dahlia who do not wish to exhibit their flowers at competitive exhibitions. In the case of such a variable flower, amateurs frequently find the question of selecting varieties a matter of considerable difficulty, and therefore the lists of varieties suitable for various purposes, contained in this book, will form a useful guide.

† "ROSES IN POTS."

A BOOK which has reached its ninth edition should require no further testimony to commend it to the notice of our readers. Messrs. Simpkin, Marshall and Co. have recently issued the ninth edition of the late William Paul's book, entitled *Observations on the Cultivation of Roses in Pots*. This work contains all the information given in previous editions, and the list of varieties has been brought up to date. It is an invaluable guide to those who cultivate Roses in pots, whether for forcing or otherwise. The concluding chapter, entitled "The Autobiography of a Pot Rose," is as interesting as it is instructive.

‡ "THE WILD RABBIT."

WE have frequent complaints from gardeners of the damage caused by rabbits, and their efforts are more frequently directed to the capture of these vermin than to their cultivation. Mr. J. Simpson's book, entitled *The Wild Rabbit*, is especially addressed to those who make it their business to cultivate rabbits in properly-formed and enclosed warrens. If rabbits could only be kept to such warrens, the gardener would be the better pleased. The book contains a vast amount of reliable information upon the habits of rabbits, their methods of feeding, and how they may best be cultivated and bred for commercial purposes. There are chapters upon the diseases to which rabbits are liable, and upon trees and plants that rabbits appear not to eat. Not only is the industry of rabbit-rearing recommended to farmers, but it is contended that the business would prove a lucrative one for allotment holders.

* By J. B. Wroe. Published by W. H. & L. Collingridge. Price 1s.

† By W. Paul. Published by Messrs. Simpkin, Marshall, Hamilton, Kent & Co. Price 2s.

‡ *The Wild Rabbit*, or Rabbit Warrens combined with Poultry Farming and Fruit Culture, by J. Simpson. Third edition, revised and enlarged. Published by Pawson & Brailsford, Sheffield.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

THE STATE AND HORTICULTURE.—I read in an article by *C. F.* on page 293, under the above heading that "Land in England is greedy and hungry, and a few thousands of pounds might soon be lost in the endeavour to improve a few acres of ground." (If the principles underlying the working of it are not understood.—ED.) That presents itself to me as an astonishing statement. Average English land is neither greedy nor poor, and by an expenditure upon it of £20 per acre to deeply work it, and a further £20 to manure it, any average land will soon become profitable. To write of expending "thousands of pounds" on a few acres is absurd. Such a sum might cover the whole area with glass. An expenditure of £100 per acre on animal manure would convert the land into a literal dung bed, fit perhaps to grow coarse leafy vegetables, but quite unsuitable for ordinary crops. Any good gardener, with but moderate financial assistance, can convert land from being comparatively barren into land that is satisfactorily productive. When Mr. Beckett went to Aldenham he was told it was not possible to grow good vegetables on the stiff soil there. But for some years past he has produced there the finest vegetables seen in the kingdom, whether grown by Frenchmen or any one else. When Mr. Mortimer settled at Rowledge, Farnham, he did go on what seemed to be, by its production of poor heath and gorse, the hungriest soil in Surrey. But now it is splendidly fertile and will grow anything well, yet he has not squandered thousands of pounds in improving his few acres. There seems to be growing up a belief that our gardening, especially of certain vegetables, is a long way behind that of other countries. That is far from being proved. Later on, I trust, opportunity will be offered at Shepherd's Bush to compare English, with French-grown fruit and vegetables. If we have anything to learn, we will learn willingly. *A. D.*

IRIS (XIPHION) TINGITANA, BOISS.—Xiphion tingitanum is an old inhabitant of our gardens, having been introduced about 1880 by Mr. G. Maw, though in Baker's "Handbook of Irideæ," p. 46, I am given the credit of having introduced it. It is figured in the *Bot. Mag.*, 6775. Another plant figured as X. tingitanum in *Bot. Mag.*, 5981, is now considered to be a form of I. filifolia, which was found on the Rock of Gibraltar by Mr. G. Maw and by myself in 1895, and is, in my opinion, a finer plant. I have had both of them in cultivation for more than 20 years, and have found that they both require rich soil and the protection of a frame to get them into flower. Both increase fast by offsets, which must be taken off in order to get flowering bulbs. I may add that they have bulbs and not rhizomes, as stated by *F. M.*, on p. 295, and that the name is not taken "from a little town near Tangiers," but from the town of Tangiers itself. *H. J. Elwes, Colesborne.*

FRUIT PROSPECTS IN SOUTH-EAST ESSEX.—The prospects of a good fruit crop are most promising. With the wind almost constantly in the east and north-east during the month of April, and the uniformly low temperature that prevailed throughout that month, the fruit blossoms of the Pear, Plum, and Cherry were retarded until the first week in May, when a favourable change in the weather took place, followed by the expansion of a profuse display of large blossoms. A week hence the Apple trees will be clothed with the expanded blossoms of pink and white. Small fruits, including Strawberries, Raspberries, Gooseberries and Currants, also promise to be plentiful. *H. W. Ward, Lime House, Rayleigh, May 12.*

GUNNERA SCABRA.—I read with interest Mr. Jenkins' article on p. 279 relating to this species. Three years ago I was engaged in the gardens at Cherkley Court, Leatherhead, and used to water one of these plants every evening during the hot season. It was planted at the head of the Lily tank in the Italian garden there. The bed was circular, and the surface soil was light, while underneath was chalk, but this plant made good growth and would easily have a leaf spread of 15 to 18 feet, as Mr. Jenkins mentions. The only protection it was given during severe weather was that afforded by mats placed over arched poles driven in the bed. The plant was a great attraction to the many people who visited those gardens when they were thrown open for promenade concerts, by the kindness of the late Mr. Abraham Dixon. *H. Heath, Hylands, Chelmsford.*

APPLE FRENCH CRAB.—If *A. D.* (see p. 277) had read the article on p. 245 more carefully he would have seen that the synonyms were not mine. In my original note (see p. 244) the word gathered should not have been placed after "varieties" on line 25. I may here say that our Apple crop has been severely injured by the inclement weather, many of the embryo buds being killed. *Fredk. Bedford, Straffan House Gardens, Co. Kildare, May 6.*

APPLE PSYLLA.—As there is still time for growers to spray their trees for this pest, they may be interested to know that the results obtained at Woburn by the use of tobacco have been as satisfactory this season as they were last year. The liquid used on this occasion was a 7.5 per cent. solution of nicotine, obtained from W. Vass & Co., Glengall Road, Millwall, which was diluted with 100, 75 and 50 times its volume of water in the various experiments. Standard trees were sprayed with the two weaker of these dilutions on the morning of May 7, and in both cases 95 per cent. of the pysila were killed. The stronger solution was not used till the afternoon of the same day, and the results were not so good, the mortality being only 60 per cent. This was due to the fact that rain fell for an hour and a half later in the same afternoon. Various other insecticides which were applied at the same time as these nicotine solutions proved comparatively ineffective. *Spencer Pickering.*

HIPPEASTRUMS AS CUT FLOWERS.—One never hears of Hippeastrums being used as cut flowers for table decorations! Yet they are the finest flowers available for such purposes, and they are capable of providing excellent effect in arrangements for banquets and other large entertainments. I have been using them as cut flowers for room decoration in tall vases. If some unopen blooms should be cut with the open ones, the former will expand in water. Those who hybridise Hippeastrums and grow them on a large scale will always have a number of flowers which are not up to the standard of show plants, but which would be invaluable for cutting and table decorations, and other uses that might be suggested. If planted in the ground under glass, and grown in sufficient heat, they would in a few years make fine clumps by throwing up offsets. I do not know of any other plant that in any way comes near the Hippeastrum for size and variability of colour. There are scarlet and crimson selfs; the same colours with striped petals, forming a conspicuous star; whites splashed, streaked, and veined with crimson, and other innumerable variations—not two alike. Where can one find such superb colouring and variation? Yet they are never seen as cut flowers at exhibitions! There seems to be a reluctance to show flowers that are not of the orthodox shapes of florists, yet no one denies the wonderfully fascinating form of the Sprekelia. I send herewith a second bloom of Hippeastrum, which has turned out to be much spotted. It is named "Spotted Angelina," and differs somewhat from the "Queen of Spots" [shown in the Supplementary Illustration to the issue for April 27, 1907], and is of the same cross, namely, *H. pardinum* and a show Hippeastrum. It has two flowers, and the flower-stem has come up before the leaves. The flower is pale in colour and profusely spotted. The photograph (not reproduced) shows the flower at natural size. Some flowers of the same cross are not spotted at all, thus they are more like the female parent. *E. Bonavia, M.D.*

SOCIETIES.

ROYAL HORTICULTURAL.

MAY 12.—There was an unusually large display of plants and flowers at the meeting of the Committees held on this date, notwithstanding the nearness of the Temple Show, which will be opened on the 26th inst.

Floral exhibits were most numerous, but there were also many fine displays before the Orchid Committee. Exhibits of outstanding merit included Ferns of hardy species, Auriculas shown by the veteran raiser and cultivator, Mr. JAMES DOUGLAS; Roses, greenhouse plants, Carnations, Gloxinias, and hardy garden and Alpine plants in great variety. Several novelties were presented to the Floral Committee, and of these five received Awards of Merit. The Orchid Committee granted no fewer than four First-Class Certificates and four Awards of Merit, and for the remarkable plant of Odontoglossum crispum "Leonard Perfect," which first appeared before the public at the Temple Flower Show, 1906, was granted the highest award—a Gold Medal. The fruit and vegetable section was poorly represented.

At the afternoon meeting a lecture on "Gardening in the West Highlands" was given by Mr. O. H. Mackenzie.

Floral Committee.

Present: W. Marshall, Esq. (Chairman), and Messrs. C. T. Druery, W. A. Bilney, R. C. Notcutt, Jno. Green, T. W. Turner, G. Reuthe, R. Hooper Pearson, W. Howe, W. Bain, Chas. Dixon, Arthur Turner, Jas. Douglas, C. E. Pearson, W. P. Thomson, W. Cuthbertson, E. H. Jenkins, W. J. James, F. Page Roberts, Jas. Hudson, Jno. Jennings, C. R. Fielder, J. W. Barr, Chas. E. Shea, Ed. Mawley, and R. W. Wallace.

Messrs. H. B. MAY & SONS, Upper Edmonton, set up a very large exhibit of Ferns of hardy species, amongst which were many crested and plumose varieties. No fewer than 350 varieties were included in this fine exhibit, which represented all the best kinds of Polystichums, Cyrtomiums, Aspidiums, Osmundas, Scolopendriums, &c. The crested forms of Scolopendriums were especially remarkable, and the Osmundas included many choice plants, noticeably some fine examples of Osmunda gracilis. A prominent plant in the centre of the exhibit was a beautiful variety of Polystichum angulare labelled P. a. divisilobum plenum. Messrs. MAY also exhibited flowering plants including Pelargoniums, Violas, Petunias, Salvias, and Calceolarias. (Gold Medal.)

Mr. JAMES DOUGLAS, Great Bookham, Surrey, furnished one of the large tables with a collection of Auriculas that embraced Alpine and show varieties in about equal numbers. The collection totalled 350 plants, and better cultivated Auriculas have never been presented at an exhibition. Mr. DOUGLAS not only possesses in his collection all the best varieties, but he is the raiser of many of the finest kinds in both sections. It is impossible to find space to enumerate all the varieties of outstanding merit, but we may instance the yellow Daffodil, Olympus, a beautiful flower of the grey-edged section, Bronze, George Lightbody, still unsurpassed as a grey-edged flower, Mrs. Henwood, a green-edged Auricula that occupies in its section the same position as does the last-named in the grey-edged class, Abbé Liszt with green margin on a black ground, Thetis, an Alpine of maroon-purple shade with a well-defined cream centre; The Bride, with large inflorescence, each pip being set off by its gold centre; Shirley Hibberd, a green-edged variety; Old Gold, Sunset, Mayday, Mikado, Argos, Dido, and a host of other beautiful kinds. (Silver-Gilt Flora Medal.)

Messrs. HUGH LOW & Co., Bush Hill Park, London, N., had a striking exhibit of blue and white-flowered Hydrangea Hortensia, Gerbera Jamesonii, Metrosideros floribunda, Brachysema Drummondii, with scarlet-coloured, pea-like blossoms, and long pendant shoots; Roses in variety, and a display of Carnations. (Silver-Gilt Banksian Medal.)

Messrs. JOHN PEED & SON, The Nurseries, West Norwood, London, S.E., showed an extensive collection of Gloxineas and an exhibit of Maples interspersed with flowering plants. (Silver Flora Medal.)

Messrs. R. & G. CUTHBERT, The Nurseries, Southgate, showed extensively Azalea sinensis, A. rustica, &c., and Cytisus purpureus incarnatus. (Bronze Banksian Medal.)

Messrs. JAMES VEITCH & SONS, King's Road, Chelsea, filled the table they usually furnish at these meetings with an exhibit of greenhouse flowerings plants, and, as a separate exhibit under the wall they showed a group of trees and shrubs in flower, and several of their new Primulas, Meconopsis, and other plants from China. The greenhouse subjects were especially attractive, and included a batch of Schizanthus, another of Cinerarias, and a mixed collection including Richardias, Statice Suworowii, Gerbera Jamesonii, Begonias of the semperflorens type, and Malvastrum grossulariæfolium. The most interesting, however, was a cut bloom of a rose-pink coloured Hippeastrum named "Doris"; the colour being distinct from any previously seen in the Amaryllis. (Silver-Gilt Flora Medal.)

Messrs. H. CANNELL & SONS, Swanley, Kent, again made one of their bright displays of Zonal Pelargoniums which appeared to be even more beautiful than ever. Carmania (rose), Cevic (flesh pink), Arabic, a scarlet flower of very large size, Duke of Bedford (crimson), and Lucania (orange, shaded with cerise) are a selection. In addition Messrs. CANNELL showed bunches of show Pelargoniums, the best of which were labelled King Haakon, Queen Alexandra, Mrs. H. Spence, and alba fimbriata. Adjoining the Pelargoniums were small plants of Hydrangeas in 5-inch pots with remarkably large inflorescences. A display of Verbenas and Roses completed the exhibit. (Silver Flora Medal.)

Messrs. JOSEPH CHEAL & SONS, Crawley, Sussex, showed sprays of interesting trees and shrubs in flower. Many of these were laden with their blossoms, especially such floriferous subjects as Pyrus Malus floribunda, Cytisus præcox, Rhododendron indicum, Daphne pontica, Lilacs, Elæagnus longipes, prunus padus, &c.

Mr. L. R. RUSSELL, Richmond, Surrey, showed a group of forced flowering shrubs which included Lilacs, Cytisus, Azaleas, Weigelas, Laburnums, &c. (Silver Banksian Medal.)

Messrs. WILLIAM PAUL & SONS, Waltham Cross, Herts., showed climbing varieties of Roses, the best of which was Tausendschon, whose clusters of pink blossoms hung in great masses from the drooping side branches. We also noticed the beautiful Aimée Muller, Hector Mackenzie, Waltham Bride, &c. (Silver Flora Medal.)

Messrs. T. ROCHFORD & SONS, Turnford Hall Nurseries, Broxbourne, Herts., showed column-trained Roses of well-known varieties, such as Lady Gay, Hiawatha, Tausendschon, Crimson Rambler, Cant's Blush, and a double-flowered sport from the last-named, shown under the name of "Gertrude Rochford." The plants were exceptionally well cultivated and were much admired. A row of Astilbe (Spiræa) japonica with fine inflorescences formed a pleasing finish to the exhibit. (Silver Flora Medal.)

Mr. G. MOUNT, nurseryman, Canterbury, showed H.P. and T. Roses in great numbers and of fine quality. The exhibit had a backing of tall plants of Rambler Roses in variety. There were arranged in huge bouquets cut blooms of C. Testout, Frau K. Druschki, C. Mermet, Capt. Haywood, Ulrich Brunner, the new H.T. Joseph Lowe, &c. (Silver-Gilt Flora Medal.)

Messrs. BENJAMIN CANT & SONS, Colchester, set up a pleasing exhibit of Polyantha and other similar types of Roses of small sizes; also cut blooms of Teas, Hybrid Teas, &c. Of the Polyantha varieties mention may be made of Edouard Proust, a white flower, with a cream-coloured centre. (Bronze Banksian Medal.)

Mr. W. H. PAGE, Tangley Nurseries, Hampton, exhibited Carnations of the American and English types, including Enchantress, Governor Roosevelt, Britannia, White Perfection, Lady Bountiful, Helen Gould, &c. (Silver Banksian Medal.)

Mr. C. F. WALTERS, Deanland Nursery, Balcombe, Sussex, showed a considerable collection of varieties of winter or perpetual-flowering Carnations. (Silver Banksian Medal.)

A very fine display of Carnations was put up by Mr. H. BURNETT, Guernsey. This was a remarkably pretty exhibit, and, in addition, the flowers were well cultivated. Suitable greenery was furnished in sprays of Asparagus and Smilax. Outstanding varieties were Mrs. Lawson, Mikado, Enchantress, White Perfection, and Robert Craig. (Silver Banksian Medal.)

Messrs. W. CUTBUSH & SON, Highgate, London, N., showed miscellaneous greenhouse plants, all of decorative flowering varieties, and choice blooms of Carnations. A new Carnation, of very large size, with creamy-white petals, was shown under the name of Mrs. Bridgeman Simpson. In the general collection of these flowers were some exceptionally fine blooms of the variety Robert Craig. (Silver Flora Medal.)

A not inconsiderable portion of the exhibition was comprised of exhibits of hardy and rock garden flowers. Messrs. BARR & SONS, King Street, Covent Garden, showed many plants of a hardy nature, including some choice forms of Iris pumila, of which the variety named after Count Andressy, with pale blue flowers, is one of the best. A gaudy scarlet Anemone, Viola pedata, Myosotis "Ditton Blue," which, as we saw it in the nursery a few days since, is a variety of much merit and valuable for spring bedding; Aubrietias, including the new A. Lavender, A. Dr. Mules, and A. tauricola, are deserving of mention.

Messrs. PAUL & SON, The Old Nurseries, Cheshunt, showed miscellaneous hardy plants, and among them were several novelties. Cytisus "Butterfly" has showy yellow and orange-coloured blooms, Aubrietia Souvenir de W. Ingram, Hydrangea arborescens grandiflora alba, with pure white flowers, appearing in large corymbs, Philadelphus purpurea maculata, Cerasus Watereri, and Pyrus japonica cononarius are all worthy of mention. Several new Roses were shown by Messrs. PAUL. (Bronze Banksian Medal.)

Messrs. G. & A. CLARK, Ltd., nurserymen, Dorset, showed some miscellaneous hardy, herbaceous plants, including Trollius, Tulips in variety, Iris, &c. This firm showed Zonal Pelargonium Mrs. W. Bealby, a bright scarlet bloom, the plant a dwarf in stature, and excellent for bedding; and Pelargonium Clark's Superb, a very large flower of a shade of cerise, an excellent variety for cultivation indoors, as we learned from the exhibitors.

Messrs. G. BUNYARD & Co., Ltd., Maidstone, showed hardy spring-flowering plants and cut blooms of such species. Aubrietias were well shown, A. tauricola being one of the brightest in colouring. (Silver Flora Medal.)

Mr. AMOS PERRY, The Hardy Plant Farm, Enfield, showed hardy plants in variety. We noted Anemone blanda, Trillium erectum, with flowers of a dark brown colour and having a green calyx; Ribes tenuiflora, having small flowers of scarlet and yellow hues, Perry's var. of Phlox canadensis, &c.

Mr. S. MORTIMER, nurseryman, Rowledge, near Farnham, showed 100 plants of Polyanthus, with flowers of four different colours.

Messrs. HEATH & SON, Cheltenham, showed Alpine plants, amongst which was a remarkably fine specimen of Ramondia pyrenaica in a pot.

Mr. JOHN R. BOX, West Wickham, showed Alpine plants and flowers of tuberous-rooting Begonias.

The Misses HOPKINS, Mere Nurseries, Shepperton-on-Thames, made a very pretty display of rock-garden plants (Bronze Banksian Medal), and a similar collection was staged by the Misses KIPPING, Hutton, Essex, who showed a very fine white form of Primula japonica in their collection.

Mr. G. REUTHE, Keston, Kent, had many rare subjects in an exhibit of hardy plants, and shown trusses of Rhododendron blooms. The flowers of Primula nivalis are blue, but the foliage has a mealy-white appearance. Mr. REUTHE also had many recently-introduced Primulas, including P. pulverulenta, P. Cockburniana, &c. (Bronze Banksian Medal.)

A selection of Polyanthus Primroses was shown by F. BOSTOCK, Esq., Springfield, Northampton (gr. Mr. J. Hollands), and a larger collection of these flowers was shown by Mr. W. A. WATTS, St. Asaph, N. Wales. Mr. WATTS had also many Auriculas, in addition to the Polyanthuses and Primroses.

Messrs. T. W. WARE, Ltd., Feltham, showed Alpine flowers. Their selection of hybrids of

Primula japonica contained many varieties of merit. In the centre of the display was a pan containing some fine plants of Cypripedium spectabile in flower.

Messrs. Dobbie & Co., nurserymen, Rothesay, N.B., made an extensive display, chief of which were fine plants of Polyanthus in variety, Pansies, and Violas. The show of Violas was a representative one. (Bronze Flora Medal.)

Mr. R. Gill, Falmouth, showed a number of trusses of Rhododendon flowers from the open garden. (Silver Banksian Medal.)

Mr. R. Upton, Guildford, showed seasonable hardy flowers in variety.

Mr. Chas. Turner, Royal Nurseries, Slough, exhibited Violas in variety, densely-flowered shoots of Ceanothus rigidus, and many plants of Primula Sieboldii. (Bronze Banksian Medal.)

Mr. M. Prichard, Christchurch, Hants, had pink, white, and blue-coloured Bluebells, in a collection of other hardy garden flowers. (Silver Flora Medal.)

An exhibit of Violas and Pansies was put up by Messrs. Carter, Page, & Co., 52 and 53, London Wall, London, E.C. We may instance Archie Grant (indigo blue), Maggie Mott (mauve), Pembroke (deep yellow), and Countess of Hopetoun (white), as varieties that are especially pleasing. (Silver Banksian Medal.)

An interesting exhibit of species of Fritillarias with other plants was shown by H. J. Elwes, Esq., Colesborne Park, near Cheltenham. The largest and showiest inflorescence was that of Fritillaria imperialis gigantea. The other species included F. acmopetala, F. latifolia, F. Kotschyana, F. obliqua, and F. pallidiflora. Other subjects shown in this exhibit were Amaryllis solandriflora, inflorescences of Bomaria edulis, and a number of beautiful Irises.

Mrs. Burns, North Mymms Park, Hatfield (gr. Mr. Fielder), again showed several well-grown white-flowered Hippeastrums, raised from seeds sown in 1905.

Awards of Merit.

Auricula "May Day." A very large, yellow flower, with white paste, each bloom being 1½ inches in diameter.

Auricula "Coronet."—A good, green-edged show variety.

Auricula "Mildred Jay."—A very large Alpine variety, purple, with lighter margins, and yellow in the interior of tube. The flowers were 1¾ inch in diameter. All these Auriculas were shown by Mr. J. Douglas.

Aubrietia "Paul's Pink."—A very effective variety, with large flowers of a rich shade of pink, shown by Messrs. Paul & Son, Cheshunt.

Asparagus filicinus. Sir Trevor Lawrence, Bart., Burford, Dorking (gr. Mr. Bain), exhibited a plant of this Himalayan species, which he obtained from Mr. Chas. Sprenger, Naples, two years ago. It has since been cultivated in a cool greenhouse, and the species is believed to be hardy or nearly so. We hope to refer to this plant in an early issue.

Narcissus Committee.

Present: H. B. May, Esq. (Chairman), and Messrs. J. T. Bennett Poe, A. R. Goodwin, G. W. Leak, H. A. Denison, J. D. Pearson, Alex. M. Wilson, R. W. Wallace, E. M. Crossfield, W. T. Ware, W. A. Milner, J. Jacob, F. H. Chapman, E. A. Bowles, W. Poupart, R. Sydenham, E. Willmott, W. Goldring, Jas. Walker, and Chas. H. Curtis (hon. sec.).

Exhibits of Narcissus were not numerous, and the flowers that were shown had not the freshness and beauty of the blooms seen earlier in the season.

Messrs. Barr & Sons, King Street, Covent Garden, London, had a rather extensive group, in which Tulips and Narcissus were about equally displayed. Of good Poeticus Narcissus, we noted Cassandra, The Bride and Horace. Also two white-flowered novelties possessing the drooping grace of N. montanus, and named respectively Sylvia and Robbie Jenkins. The Tulips included both cottage and Darwin kinds, also many good bedding sorts in single and double varieties. (Silver Flora Medal.)

Mr. Alex. M. Wilson, Post Keal Manor, Spilsby, had some very choice varieties of Narcissus. The flowers were fresh and good; indeed, nothing finer has been seen this season than the blooms of Will Scarlett, while others, such as Eoster (white, with lemon cup), Bernardino (a lovely Leedsii with big apricot-tinted crown), Concord (a very shapely flower with large, flattish crown), and Mrs. Vincent (a good white Ajax) were almost equally fine. Some excellent late Poeticus varieties were shown by this exhibitor. (Silver Flora Medal.)

Messrs. Wallace & Co., Colchester, in addition to a variety of choice Narcissi, had a still greater variety of Tulips. Amongst the Narcissi, Pride of Haarlem, Fanny (soft pink), Scarlet Emperor, Orange King, Elegans alba, Feu Ardente, and Flame are deserving of mention. Several choice Alpine plants were also shown. (Silver Flora Medal.)

Bedding and cottage Tulips in many showy varieties, staged by Messrs. Jas. Veitch & Sons Ltd., Chelsea, constituted a fine display.

Mr. F. Herbert Chapman, Rye, Sussex, had a small exhibit of choice Narcissus, a large number being of the Poeticus varieties, including Cassandra, Horace, The Bride, Glory, &c. Brass Bell is a large, self, yellow kind with bold crown of a uniform tone of colour. Mr. Chapman also showed several unnamed seedlings of merit.

Miss K. Spurrell, Manor House, Babbington, had a small exhibit of choice varieties, the blooms of F. C. T. Spurrell, a lovely white flower, with flame-scarlet Englehearti crown, being perhaps the finest among novelties. (Bronze Flora Medal.)

A display of Tulips and Narcissi was shown by Messrs. R. H. Bath & Co., Wisbech, the exhibit including many good sorts, such as Wemdale Perfection, Mme. de Graaff, Cassandra, Glory, Homer, &c. (Bronze Banksian Medal.

Award of Merit.

Narcissus poeticus Snowshoe.—A shapely and handsome variety of the Poeticus group, valuable for its late season of flowering. Shown by Mr. Walter Ware, Bath.

Orchid Committee.

Present: J. Gurney Fowler, Esq. (in the chair), and Messrs. Jas. O'Brien (hon. sec.), Harry J. Veitch, De B. Crawshay, H. Little, W. Boxall, R. G. Thwaites, F. Sander, A. A. McBean, J. Cypher, H. G. Alexander, A. Dye, F. J. Thorne, W. H. White, H. Ballantine, Gurney Wilson, W. Bolton, Norman C. Cookson, W. Cobb, J. Wilson Potter, Stuart Low, F. M. Ogilvie, F. J. Hanbury, C. J. Lucas, and H. A. Tracy.

The event of the meeting was the showing of a magnificent plant of the noble Odontoglossum crispum "Leonard Perfect" (see fig. 144) by Norman C. Cookson, Esq., Oakwood, Wylam (gr. Mr. H. J. Chapman), and for which a First-Class Certificate was unanimously awarded, and also the Society's Gold Medal,

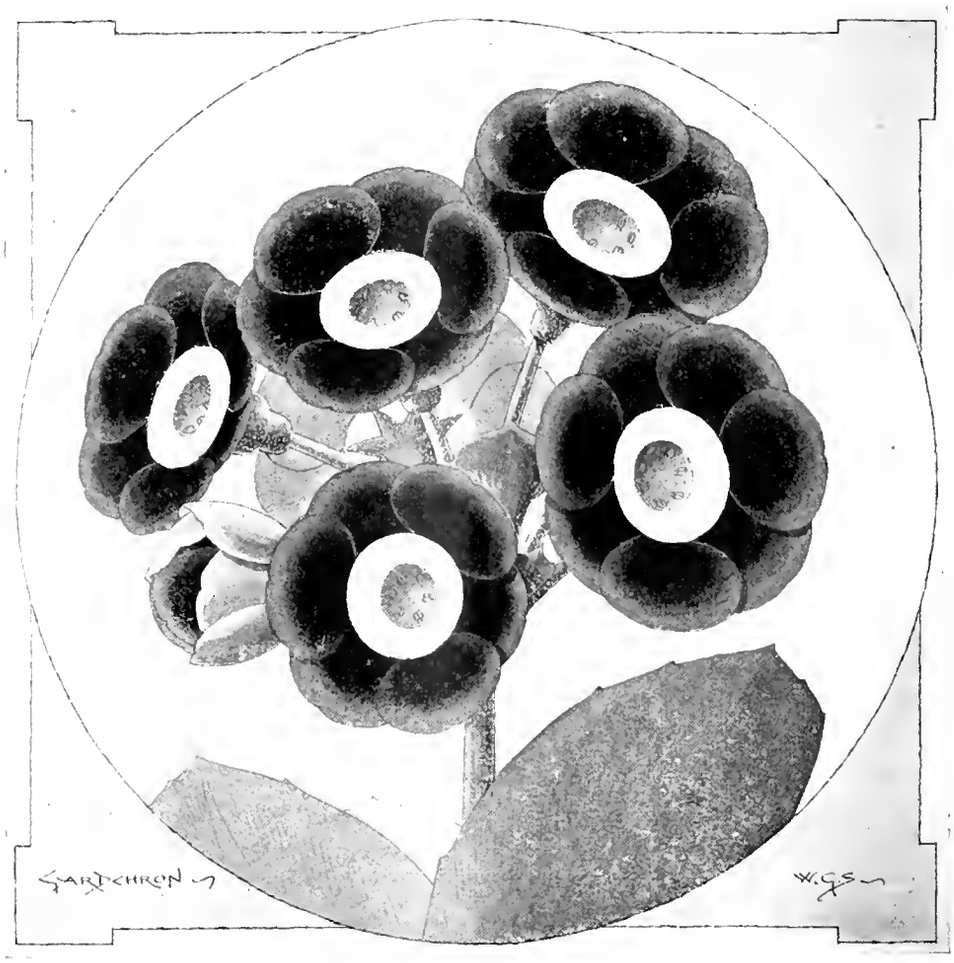

Fig. 143.—Alpine auricula "Phyllis," which received an award of merit at the meeting of the royal horticultural society on April 28. The centre of the flower is cream-coloured; segments purple shading to mauve.

(See report in the issue for May 2, p. 290.)

in recognition of the high merit of variety, and the very fine state of cultivation in which it was presented, the stout inflorescence bearing many flowers, each 4½ inches across of perfect shape and of very fine substance. The plant was originally shown by Messrs. Sander & Sons at the Temple Show, 1906, and illustrated in the *Gardeners' Chronicle*, June 2, 1906, pp. 348-9, and it is interesting to note that the broad segments and the large size of the flower is sustained on the heavily-flowered spike now on the plant. It is generally conceded that among blotched O. crispum there is nothing like O. c. "Leonard Perfect," and it is difficult to conceive an advance beyond it, the masses of bright violet-purple colouring, which take up the inner halves of the segments, being very characteristic. Moreover, it has a showy labellum, and is of the highest order of merit at all points.

Sir Trevor Lawrence, Bart., K.C.V.O., Burford (gr. Mr. W. H. White), staged a select group, in which were a finely-flowered plant of Brasso-Cattleya × nivalis, with very pretty white flowers; a very handsome form of Dendrobium crepidatum, with wax-like rose-tinted flowers; the pure white Cattleya Dusseldorfei var. Undine; the little yellow Maxillaria variabilis; and others. (See Awards.)

Major G. L. Holford, C.I.E., C.V.O., Westonbirt (gr. Mr. H. G. Alexander), Odontoglossum crispum var. Zoroaster, very strongly grown, and bearing a fine spike of large rose-tinted flowers with some small spotting on the inner parts of the segments.

J. Gurney Fowler, Esq., Glebelands, South Woodford, showed the finely-blotched Odontoglossum crispum Britannia and the handsome O. Ossulstonii, Glebelands variety, which gained an Award of Merit.

H. S. Goodson, Esq., Fairlawn, Putney (gr. Mr. G. E. Day), staged a neat group, in which were a very fine variety of Cælogyne pandurata, Brasso-Cattleya Digbyano-Mossiæ of fine colour, Cypripedium Maudiæ, C. callosum Sanderæ, Masdevallia Veitchii, M. ignea, and other brightly-coloured Masdevallias, &c. (Silver Banksian Medal.)

Messrs. J. Cypher & Sons, Cheltenham, had an effective group, the back of which was of excellent varieties of Lælia purpurata, with good white Odontoglossum crispum, &c., the front being composed of bright scarlet and purple Masdevallias, Cattleya intermedia alba, very finely-coloured Lælio-Cattleya Hyeana, a distinct rose-coloured form of Brasso-Cattleya Digbyano-Mossiæ with deep yellow disc to the lip, and other plants. (Silver Flora Medal.)

Messrs. Jas. Veitch & Sons, Royal Exotic Nurseries, King's Road, Chelsea, staged an effective group, in the centre of which was a specimen of their beautiful Brasso-Catlaelia Veitchii, for which they received a First-Class Certificate April 16 last year. It was obtained between Brasso-Cattleya Digbyano-Mossiæ and Lælia purpurata, and may be likened to a fine Cattleya Warscewiczii with a deeply-fringed lip. In the group the many plants of Odontoglossum Pescatorei were of an exceptionally good strain, the labellums being large and variously decorated with purple. Good Odontoglossum crispum and various Lælio-Cattleyas were also in the group, which secured a Silver Flora Medal.

M. Maurice Mertens, Mont St. Amand, Ghent, showed a selection of good hybrid Odontoglossums, Cattleya Schroderæ alba, &c., for which a Silver Banksian Medal was awarded.

De B. Crawshay, Esq., Rosefield, Sevenoaks, (gr. Mr. Stables), showed a selection of Odontoglossums, including O. crispum, Mrs. de B. Crawshay, and O. c. Isolde, two of the finest white forms yet shown and both magnificent plants; O. Queen Alexandra var. fulgens of very rich colour, O. Nerissa (nævium × crispum), white, densely spotted with red; O. Urania (crispum × cristatellum) and one other. (See Awards.)

Pantia Ralli, Ashtead Park, Epsom, sent Dendrobium Rallianum (Hildebrandii × splendidissum grandiflorum) and its variety album.

Miss Willmott, Warley Place, Great Warley, showed Maxillaria porphyrostele, a pretty dwarf species of the M. picta section.

H. J. Bromilow, Esq., Rann Lea, Rainhill, Lancashire (gr. Mr. W. J. Morgan), sent Cypripedium bellatulum album and C. bellatulum var. Queen of Spain, a remarkable variety, which was imported as C. bellatulum album, which it resembles except that its flowers are cream-white with a slight rose shade and with very obscure pale rose spotting.

The Hon. Mrs. Foley, Packham, Fordingbridge, Hants, sent a fine spike of the rosy-lilac coloured Lissochilus purpuratus, illustrated in the *Gardeners' Chronicle*, May 13, 1905, p. 290.

Mr. A. W. Jensen, Lindfield, Haywards Heath, showed several forms of his best strain of Odontoglossum and Cattleya Mendelii Lindfieldensis, a fine flower with magenta-rose front to the lip.

Messrs. Hugh Low & Co. showed varieties of Cattleya Mendelii, Dendrobium Bronckartii, D. thyrsiflorum, &c.

Reg. J. Farrer, Esq., Clapham, Yorks, sent Odontoglossum crispum Anne Boleyn, a pretty white variety with several reddish-purple blotches on the sepals, and Cypripedium Queen of Italy, pale yellow, with small purple spots on the petals and dorsal sepal.

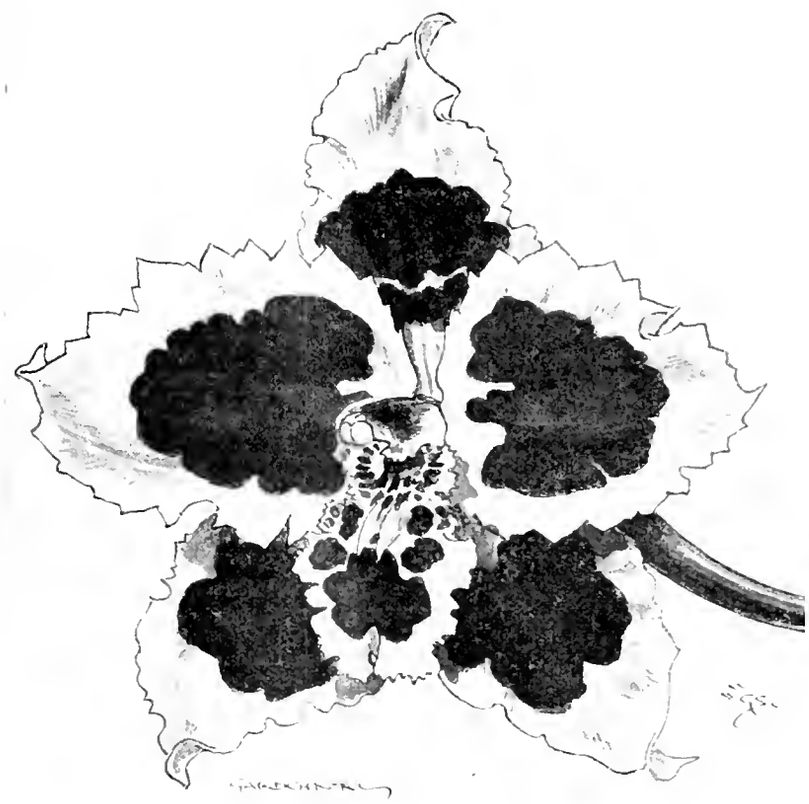

Fig. 144.—Odontoglossum crispum "Leonard Perfect," awarded a gold medal and first-class certificate on Tuesday last.

Awards.

First-Class Certificates.

Odontoglossum crispum "*Leonard Perfect*," from Norman C. Cookson, Esq. (gr. Mr. H. J. Chapman). Flowers 4¼ inches across and very broad in all the segments, white with bright violet-purple blotches covering the inner two-thirds of the segments (see fig. 144).

Cattleya Mossiæ Gerasiana, from Sir Trevor Lawrence, Bart., K.C.V.O. (gr. Mr. W. H. White). A superb and very distinct form which has been in the Burford collection for many years. It is nearest to C. M. Reineckiana, but the sepals and petals are pearly white, the fine, crimped lip deep reddish-violet, with white margin.

Brasso-Cattleya Heatonensis, *Westonbirt variety* (*B. Digbyana* × *C. Hardyana*), from Major G. L. Holford, C.I.E., C.V.O. (gr. Mr. H. G. Alexander). A charming flower of a yellowish ground colour tinged with pale rose, the large, fringed, trumpet-shaped labellum having the disc of a delicate yellow colour tinged with emerald green. This well-grown plant bore a spike of three blooms.

Odontoglossum Wilckeanum Schroderianum, from Baron Sir H. Schroder, The Dell, Egham (gr. Mr. H. Ballantine). This is the superb variety which received an Award of Merit on December 19, 1905. Its large, light yellow flowers are of fine substance and heavily marked with chestnut-red, the petals and lip being fringed. The specimen shown was very finely developed by good cultivation.

Awards of Merit.

Odontoglossum Ossulstonii, *Glebelands variety* (*Pescatorei Charlesworthii* × *crispo-Harryanum*), from J. Gurney Fowler, Esq., Glebelands, South Woodford. A very distinct and handsome variety, with the clear white ground colour of O. Pescatorei, richly marked with claret colour. The plant bore a very strongly-branched spike of many flowers.

Odontoglossum illustre var. Theodora (*Vuylstekei* × *ardentissimum*), from De B. Crawshay, Esq. (gr. Mr. Stables). A pretty new departure in colour, the younger flowers being of a light bronzy hue tinged with pink and changing when approaching maturity to rosy-mauve, with a silver-white margin to the segments.

Odontoglossum nebulosum Mossiæ, from J. S. Moss, Esq., Wintershill Hall, Bishops Waltham. Flowers of fine shape, pure white, with yellow crest to the lip. It is the best white form of the section of O. n. candidulum.

Angræcum Germinyanum, from Sir Trevor Lawrence, Bart., K.C.V.O. (gr. Mr. W. H. White). A very elegant dwarf species bearing white-lipped flower with slender petals and longer twisted spurs gracefully arranged. The little plant bore four flowers.

Botanical Certificate.

Epidendrum leucochilum, from Sir Trevor Lawrence, Bart. A singular plant, with leafy stems bearing flowers having greenish sepals and petals and white trilobed lip.

Eria amica, Rchb. f., from Sir Trevor Lawrence, Bart. Flowers in closely-arranged racemes, each furnished with a bract; whitish striped red; lip yellow.

Megaclinium velutinum, from Sir Trevor Lawrence, Bart. A West African species, with flat, purple rachis, bearing singularly-formed flowers.

Fruit and Vegetable Committee.

Present: Geo. Bunyard, Esq. (Chairman), and Messrs. Jos. Cheal, J. Willard, A. Dean, H. Parr, A. R. Allan, Jas. Vert, O. Thomas, Chas. Foster, Geo. Wythes, Jno. Harrison, C. G. A. Nix, A. H. Pearson, Ed. Beckett, H. Markham, Geo. Kelf, W. Poupart, and J. Davis.

The only noteworthy exhibit before this committee was a collection of vegetables staged by Messrs. James Veitch & Sons, Ltd., King's Road, Chelsea. The collection included some well-developed Cabbages of the variety Incomparable. The seeds were sown on July 1, 1907, and the heads were regarded by the Committee as representative of an excellent type of this vegetable. The other vegetables included Early Forcing Carrot, Veitch's Climbing French Bean, Tomatos, Lettuces, &c. (Silver Banksian Medal.)

ROYAL GARDENERS' ORPHAN FUND FESTIVAL DINNER.

MAY 12. The festival dinner of the friends and supporters of this charity, held on the foregoing date, had additional interest in that it was the 21st anniversary of the establishment of the fund. To properly celebrate the "Coming of Age," every effort was made to augment the funds of the Charity, and we are glad to be able to announce that the result is a very satisfactory one.

The dinner took place in the Victoria Room of the Hotel Cecil, London, and His Grace the Duke of Bedford, K.C., President of the Fund, occupied the chair.

The guests numbered 176. As is usual on these occasions, the tables were beautifully decorated with flowers, contributed by various friends of the charity. After the observance of the usual loyal toasts, the President proposed that of "The Royal Gardeners' Orphan Fund." His Grace referred to the importance of the gathering as representing the 21st birthday of the fund. Proceeding to speak of the objects of the Charity, he said no darker shadow could hang over a man than the knowledge that he might at his death leave children for whom there was no provision. It was customary to regard the children of gardeners as encumbrances, simply because they did not tend to the convenience of the employer, but it was wrong to penalise a man because he was a husband and a father. It was unwise from a national point of view to do anything that was calculated to encourage a low birth rate. The fund was at present supporting 116 children, and he appealed for increased financial help, and especially for more annual subscriptions. The cost of management being fully met by the income from the invested capital, all revenue arising from subscriptions was directly available for relief purposes. He therefore made an appeal for increased support in order that the benefits of the institution might be extended over a still larger area.

The hon. treasurer, Mr. Edward Sherwood, thanked his Grace for presiding that night, and stated that a great effort had been made to make the festival a record one. He himself had brought the objects of the charity before the notice of many friends in the more distant parts of the provinces. In doing this he was impressed with the fact that the Charity was little known among the smaller horticulturists in the country. The fund had distributed during 1907 £100 more than in any previous year. He had pleasure in announcing that in commemoration of the 21st anniversary of the fund, his father, brother and himself had decided to contribute a sum of £300 to provide a special section of the Fund to be known under the name of "Maybud Campbell."

The toast of "Gardeners and Gardening" was given by the Mayor of Westminster, John W. Dennis, Esq., J.P., who declared that successful gardening demanded much knowledge, not only of the sciences connected with it but also of commercial principles. Dr. J. B. Farmer, F.R.S., who responded to this toast, urged the necessity of adopting modern methods and for acquiring technical knowledge. He advocated the claims of horticulture at the universities, and stated that it rested with gardeners themselves as to whether their demands should be recognised in the same manner as those of agriculture. A neighbouring country had recently recognised horticulture officially in the creation of a special department for the profession.

The toast of "The Visitors" was given by Mr. W. Pompart, who compared the fund to a "sport" which had originated in 1887, and which began fruiting at once, but contrary to some plants the early fruiting had done it no harm. The "sport" needed increased nutriment in the shape of more funds. Mr. Arnold White, who responded to the toast, spoke of the duties of employers to gardeners and of those of gardeners to their employers. He advocated a better status for the gardener, whose position was at present often below that accorded to other employés on an estate.

The secretary, Mr. Brian Wynne, announced that the attendance at the festival was a record one, and that the contributions far exceeded those obtained on any previous occasion. Some of the principal subscriptions were as follow:—The Duke of Bedford (President), £250; and Messrs. Leonard Sutton, £100; G. H. Cuthbert, £63 10s.; Geo. Reynolds, £60 10s.; J. F. McLeod, £55; R. B. Leech, £22 10s.; R. Hooper Pearson 14 guineas, including £5 5s. from the *Gardeners' Chronicle*, Ltd.; D. W. Thomson, £14 18s. 6d.; T. W. Sanders, £14 3s. 6d.; Harry J. Veitch, £10; W. P. Thompson, £9 8s.; and the Thames Bank Iron Company, six guineas. Supporters at Covent Garden Market had contributed £260 13s. 6d. The popular shilling collection had resulted in £229, representing 4,580 shillings, and he had hopes of receiving more donations from this source, as money was still arriving from collectors in this country. The above subscriptions, together with smaller sums, amounted to a grand total of £1,385, but this did not include the £300 contributed by Messrs. Sherwood to found the "Maybud Campbell" Fund.

SCOTTISH HORTICULTURAL.

MAY 5.—The monthly meeting of this association was held on the above date, Mr. Whytock, the president, being in the chair. There was a large attendance. Mr. Wm. Austin, Comely Bank Nurseries, Edinburgh, read an interesting paper on "Alpine Plants," the major part of which dealt with the cultivation of some of the more difficult subjects, such as the varieties of Saxifraga Burseriana, Gentiana bavarica, various Primulas, Ramondia, Aphyllanthus, Bryanthus, Shortia, Schizocodon, Andromeda fastigiata, Rhodothamnus Chamæcistus, Haberlea, Ranunculus glacialis, Lewisia, &c. The subsequent discussion was taken part in by the president and Messrs. James Grieve, R. Morris, T. Hay, G. P. Berry, and C. Comfort.

The following plants were exhibited at the meeting:—Flowers of Bruntelsia violacea, from Mr. T. Hay, Hopetoun; 17 species and varieties of Primula, three species of Saxifraga, and Androsace pyrenaica, from Messrs. CUNNINGHAM, FRASER & CO., Edinburgh; three seedling plants of Primula Cockburniana, from WM. ROBERTSON, Piling House, Edinburgh; 14 varieties of Gloxinia to show strain (highly recommended) and Spiræas (Astilbe) "Peach Blossom" and "Queen Alexandra," from Mr. JOHN DOWNIE, Nurseryman, Edinburgh; twin flower of Richardia africana (Calla æthopica), from Mr. R. DAVIDSON, Kinloch Castle, Rhum; seedling White Daisy (flower about 2 inches across), from Mr. C. COMFORT, Broomfield, Davidson's Mains; eight varieties of Sweet Peas, and Souvenir de la Malmaison Carnation "Duchess of Westminster," from Mr. J. CONNOCHIE, JUN., Ayton; 12 vases of Narcissi in 10 varieties, from plants naturalised in grass, from Mr. JAS. LITTLE, Saughton House, Edinburgh; Cattleya citrina, Cypripedium callosum, C. Sallieri, C. Pitcherianum, C. signatum × C. Sanderianum, and Polystichum angulare var. Grimmondii, from Messrs. JAMES GRIEVE & SONS, Nurserymen, Edinburgh (highly commended).

Fifteen new members were elected.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

APRIL 30.—*Committee present:* Messrs. J. Ashworth (chairman), R. Ashworth, Cypher, Upjohn, Ward, Keeling, Shill, Cowan, Warburton, Parker, P. Smith and Weathers (hon. sec.).

A. WARBURTON, Esq., Vine House, Haslingden (gr. Mr. Dalgleish), displayed an exhibit of Cattleyas and Lælias. C. Mendelii var. "The Monarch," having segments of a pale colour, received an Award of Merit, a similar distinction being conferred on C. Schröderæ var. "The Don." A Silver Medal was awarded for the collection, and the same exhibitor obtained a Bronze Medal for an exhibit of Cypripediums.

J. MCCARTNEY, Esq., Bolton (gr. Mr. Holmes), was awarded a Silver Medal for a mixed group of Orchids and a Bronze Medal for a collection of Cattleyas and Lælias. Cattleya Mendelii var. Alice McCartney was granted an Award of Merit.

Z. A. WARD, Esq., Northeaden (gr. Mr. Weatherby), was awarded a Silver Medal for an exhibit of Odontoglossums, in which were several choice varieties, including Odontoglossum × Phœbe, Ward's var., a hybrid between O. cirrhosum and O. crispum var. punctatissimum. This plant received an Award of Merit.

E. ROGERSON, Esq., Didsbury (gr. Mr. Price), exhibited Dendrobium × Dalhou-nobile, a distinct plant, well grown, and pleasing in character. A Cultural Certificate was given for a specimen of Lycaste × Balliæ var. Mary Gratrix exhibited in this collection.

H. J. BROMILOW, Esq., Rainhill, Liverpool (gr. Mr. Morgan), is a strong competitor in the "Sander" Cup competition, and on this occasion he was awarded a Silver Medal for a good group of these Orchids and an Award of Merit for Cypripedium × Hopkinsianum var. Bromilowæ.

S. GRATRIX, Esq., Whalley Range (gr. Mr. Shill), obtained a First-Class Certificate for Cattleya Mendelii var. "Mrs. Joynson Hicks," a fine variety with white sepals and petals, and a slight colouring in the lip. Dendrobium × Leeanum var. magnificum received an Award of Merit.

Messrs. CYPHER & SONS, Cheltenham, staged a meritorious group of plants, consisting of Cattleyas, Dendrobiums, Odontoglossums, &c. Especially fine was a plant of Miltonia vexillaria with 15 spikes of flower. (Silver Medal.)

MR. W. SHACKLETON, Great Horton, Bradford, was awarded a Bronze Medal for a miscellaneous collection, and a similar award was made to Messrs. KEELING & SONS, of West Gate Hill, Bradford, for a small group.

Mr. J. BIRCHENALL, Alderley Edge, staged a few plants of interest, among which was Cycnoches pentadactylon. *P. H.*

BRITISH GARDENERS' ASSOCIATION.

(LEEDS BRANCH.)

MAY 2.—The Committee of this branch intend to make the Grand Central Hotel, Leeds, their headquarters, and to hold bi-monthly meetings during the summer.

A successful start was made on Saturday, May 2, when Mr. H. J. Clayton, of Ulleskelf, York, gave a lecture on "Gardeners and Gardening." Mr. Clayton dealt chiefly with the training of young gardeners.

An appeal was made for the popular shilling fund of the Royal Gardeners' Orphan Fund, which met with much support from those present.

Mr. John Donoghue, Bardon Hill Gardens, Leeds, will give the next lecture on July 4, 1908, at 7.30 p.m., the subject being "The Carnation, its History and Cultivation." The lecturer will also exhibit many varieties of this flower. All gardeners are cordially invited to attend.

CROYDON SPRING FLOWER SHOW.

MAY 6.—The eighth annual spring flower show of the Croydon and District Horticultural Society was held at the Horniman Hall, Croydon, on this date. Admission was free to the general public, and in consequence the number of visitors attending the show was very large. No prizes were offered to the exhibitors. From the gardens of the president, J. J. REID, Esq. (gr. Mr. F. Oxtoby), came a grand exhibit of Schizanthus, Azaleas, and Mignonette. Mr. A. Edwards (gr. to J. PASCALL, Esq.) showed a miscellaneous group of plants, including well-grown Calceolarias and double-flowered Cinerarias. Mr. C. Lane (gr. to C. H. COLES, Esq., Caterham) exhibited well-grown Hippeastrums and Caladiums. An effective display of Cineraria stellata, also Cyclamen and White Stocks, was arranged by Mr. A. DYER. SIR WALPOLE GREENWELL (gr. Mr. W. Lintott) sent cut flowers including double and regal Pelargoniums, Cypripediums, and two fine sprays of Cymbidium Lowianum. A very fine plant of Azalea, measuring about 2 feet 6 inches in diameter, was shown by Mrs. MATTHEWS (gr. Mr. C. Trower). A pretty exhibit was made by Mr. Wateridge (gr. to Mr. OTTO HEHNER) with Cineraria stellata. Spiræas and Hippeastrums from the gardens of F. ALLEN, Esq., were also much admired, and the Society welcomed a new exhibitor in his gardener, Mr. Beacon. Mr. J. R. FOLCE showed well-grown Auriculas, and Mr. R. CLEVELAND a collection of Cacti. Trade exhibits were well represented. Messrs. J. PEED & SON, West Norwood, showed a collection of Alpines and Carnations. An exhibit of Alpines was also shown by Mr. J. R. BOX, West Wickham, who also staged Tulips and Narcissi. Mr. P. CHAFF arranged a miscellaneous group of plants, and the staged was decorated by Mr. T. BUTCHER. Messrs. E. W. & S. ROGERS showed Hyacinths

DUTCH BULB GROWERS.

APRIL 22.—At a meeting held on this date the following awards were made by the committee appointed to judge Narcissus and other bulbs:—

FIRST-CLASS CERTIFICATES were awarded to: Narcissus General Baden Powell (a deep yellow trumpet Daffodil); N. Sulphur Beauty (having a white perianth and clear sulphur-coloured trumpet); N. bicolor "Dick" (white perianth and yellow trumpet); Astilbe Queen Alexandra and Astilbe Peach Blossom, both of a handsome rosy-pink colour and good free-flowering varieties for early forcing.

AWARDS OF MERIT were given to Narcissus E. H. Krelage, a very early free-flowering trumpet Daffodil with light yellow perianth and pure yellow trumpet; N. "Mr. van Noort," a cross between Emperor and Golden Spur, a large flower with broad yellow trumpet and light yellow perianth; N. "Sir Henry Campbell-Bannerman," having a deep yellow trumpet and yellow perianth with rather pointed petals; N. bicolor "Giant," with fine broad trumpet and creamy-white perianth, a large flowering, strong-growing variety; N. bicolor "Miss Ellen Terry," with clear yellow trumpet and white perianth; N. "Snow Queen," a white trumpet Daffodil with curling petals; and N. "Tom," with dark yellow trumpet and yellow perianth, a large flowering variety. In addition to the awards mentioned above, a Gold Medal and other awards were made to various exhibits in recognition of high culture.

LAW NOTE.

TRADE NAME DISPUTE.

IN our issue for April 11 last, p. 236, we referred to a law case in which Messrs. Alexander Dickson & Sons, Ltd., the well-known Rose growers, carrying on business in Dublin, Belfast, Newtownards, and in England, claimed an injunction against Mr. Alexander Dickson, of Dublin, trading as Alexander Dickson & Sons, restraining him from using the plaintiffs' trade name without taking reasonable precautions to distinguish the business carried on by him from the plaintiffs' business.

The Master of the Rolls, in delivering judgment, said: The plaintiffs have a trade name, and they have the right that no man shall wrongfully interfere with their name. I consider that the words of Lord Esher contain in the clearest manner the right to use a man's real name, but Lord Esher says that no man has the right to pass off his goods as the goods of another. I am of opinion that the defendant has used, for the purposes of advertisement, a name to which he has no right, and I think that in advertising his goods under the name of Alexander Dickson & Sons he was advertising them under a false name, or at all events under a name which was assumed for the purpose of attracting business which belonged to another man. The defendant describes himself as possessing "the home of the Rose" and "Dickson's choicest selections." If the words "Ashbourne Agricultural Co." had appeared at the bottom, I do not think that the slightest objection could have been made; but as it stands, I do not entertain any doubt that the advertisement was framed with the object of representing to the public that the plaintiffs, the world-wide Rose growers, were the owners of the Woodlawn Nurseries, Dundrum; and the fact that some members of the public were so deceived has been placed beyond doubt. My order will not be one which will prevent the defendant using his own name, or prevent him entering into partnership and calling himself Alex. Dickson & Sons, but it will prevent him using that name without taking reasonable precautions to distinguish business carried on and goods sold by him from those of plaintiffs, or for carrying on business so as to mislead the public.

MARKETS.

COVENT GARDEN, May 13.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—ED.]

REMARKS.—The last consignment of Nova Scotian Apples for the season has arrived. Oranges of best quality continue to sell freely and at good prices. Esopus Apples from South Australia are now arriving in good condition, but the

supply is very limited; the variety represents one of the best dessert Apples on the market, and the fruits have a quick sale. Strawberries are still plentiful, and the demand is poor, 3s. per lb. being the top price for best berries; those of second quality in ½ lb. punnets have a quick sale, but at low prices only. Grapes from Australia are expected to arrive this week. Mushrooms are a little firmer. Trade generally is quiet. *E. H. R., Covent Garden, Wednesday, May 13, 1908.*

Remarks.—Trade is very quiet and prices are not so firm. Supplies are equal to all demands.—*E. J. Newborn, Covent Garden and St. Pancras, May 13, 1908.*

COVENT GARDEN FLOWER MARKET.

During the past week trade has improved. Flowering plants have been in demand and bedding plants are selling freely. The demand for cut flowers varies considerably; since the advent of warmer weather supplies have been excessive.

Pot Plants.

Ivy-leaved Pelargoniums, of the type used for furnishing window boxes, have a ready sale. Extra fine plants of Galilee realise from 12s. to 15s. per dozen; these are used for floral decorations; smaller plants for window boxes are worth from 6s. to 8s. per dozen. Of Marguerites, some of the plants have sold at 12s. to 15s. per dozen, but 8s. per dozen is about their average value. Zonal Pelargoniums are now at their best, especially the single varieties, including Mrs. Cannell (salmon), Mrs. Brown Potter (pink), and Snowflake (white). Of the semi-double-flowered section are seen Mrs. Lawrence, King of Denmark, Ville de Portiers, and Madame Rosaine. Spring-sown Mignonette is to be had, but the plants are scarcely forward enough. Lobelia is now well in flower. Harrison's Musk, Rhodanthe, and Petunias are good. Plants of Erica ventricosa, E. magnifica, E. hybrida, and E. translucens are well flowered. Verbena Miss Willmott is a prominent subject on the stands. At Messrs. H. B. May and Sons' nurseries I recently noticed several other varieties, but there will probably never be another more popular than the lovely pink variety named after Miss Willmott. Spiræas include S. multiflora compacta, S. astilboides floribunda, and the ordinary type of japonica, the last-named is still favoured by many growers, as the flowers are pure white and they last for a considerable time as cut blooms. Boronia elatior and B. heterophylla are good, but B. megastigma is almost finished. Ferns are not so plentiful. Palms are well supplied. Acer Negundo variegata is very good; there appears to be no fixed prices for this useful plant, which averages from 2s. to 5s. each.

Cut Flowers.

Carnations are over abundant, but best blooms have been making advanced prices; the border variety, Duchess of Fife, is now beautiful, but the flowers appear small when compared with those of the winter-flowering varieties. Roses are very plentiful, and growers must be disappointed with their returns. Smaller blooms of varieties such as General Jacqueminot are more profitable than finer blooms with long stems. Daffodils have suffered from the bad weather. Spanish Irises are abundant, and their prices have fallen considerably. Gladiolus The Bride and other hybrid varieties are seen. Darwin Tulips are very fine, and the weather has not damaged them to the same extent as the ordinary sorts. Stephanotis, Tuberoses, and Gardenias are plentiful. White Azalea is nearly over for the season, and Camellias are of doubtful quality. Lilium longiflorums of the best quality are very cheap. Supplies of Callas are excessive. Coloured Sweet Peas are more valuable than "whites." Statice sinuata can be had in white, blue, and yellow colours. *R. H., Covent Garden, Wednesday, May 13, 1908.*

GARDENING APPOINTMENTS.

[*Correspondents are requested to* ***write the names of persons and places as legibly as possible.*** *No charge is made for these announcements, but if a small contribution is sent, to be placed in our collecting Box for the Gardeners' Orphan Fund, it will be thankfully received, and an acknowledgment made in these columns.*]

Mr. E. Hodgson, for the past 10 years Gardener to Miss Mortimer at the Royal Crown Hotel, Sevenoaks, as Gardener to F. A. Forbes, Esq., Godden Green, Sevenoaks, Kent.

Mr. M. Loasby, for the past 2 years Gardener at "Lechlade Manor," Glos., previously 6 years Gardener to Sir B. Samuelson, Bart., "Bodle de Grange," as Gardener to Lady Maud Hastings, "The Manor," Ashby-de-la-Zouch, Leicestershire. (Thanks for contribution to R.G.O.F. box).

Mr. George Bristol, for the past 10½ years Gardener to Charles Edward Lambert, Esq., Manor House, Effingham, Surrey, as Estate Bailiff and Gardener to the same gentleman. (Thanks for your donation of 2s. 6d. which has been placed in the R.G.O.F. box.)

THE WEATHER.

THE WEATHER IN WEST HERTS.

Week ending May 13.

A week of "growing" weather.—During the past week there have been only two cold days and one cold night, but the nights, as a rule, have been much more unseasonably warm than the days. On the one cold night the exposed thermometer registered 4° of frost. The ground is now at about a seasonable temperature, both at 1 and 2 feet deep. Since the month began some rain has fallen on all but three days, but to the total depth of only about 1 inch. The percolation through both the soil gauges is now slackening, and only small quantities are each morning recorded. The sun shone on an average for 5¾ hours a day, which is about a seasonable record for this period in May. The winds were rather high at the beginning of the week, but since then light airs alone have prevailed. In the windiest hour the mean velocity amounted to 16 miles—direction W.S.W. There was a seasonable amount of moisture in the air at 3 p.m. *E. M., Berkhamsted, May 13, 1908.*

ENQUIRY.

Sunflower Seeds for Feeding Game.—Can any reader inform *A. C.* the best methods of cultivating Sunflowers on a large scale for producing seeds for feeding game?

ANSWERS TO CORRESPONDENTS.

Carnation Failing: *Correspondent.* There is no fungus disease present in the plant, but the lower portion of the stem has been hollowed by some boring insect. Soak the soil with a solution of nitrate of potash, using 2 ozs. of the salt in each gallon of water.

Caterpillars Destroying Cabbage Plants: *L. Fosbrooke.* One of the so-called "surface caterpillars" being the larva of the Heart and Dart Moth (Agrotis exclamationis). The methods of control generally recommended are to apply dressings of soot and lime and to hoe the crops frequently, thus encouraging the presence of rooks and starlings. You might try spraying the stems of the plants with Paris Green (poison) at the rate of one ounce to 20 gallons of water.

Caterpillars on Currant Trees: *Trinity.* Larvæ of the common Magpie or Currant Moth (Abraxas grossulariata). The larvæ of this insect hibernate through the winter in or near the plants—often in the dead leaves attached to the branches; they reappear in spring, and when fully developed usually crawl away from the plant, and often spin their cocoons under window-sills, projecting coping-stones, &c. The cocoon consists of a loose network of silk enclosing a black chrysalis with yellow abdominal bands. Spray the infested trees with Paris Green (poison) at the rate of one ounce to 20 gallons of water. Caution.—Use this with great care as it contains a fair amount of free arsenic. Keep the water constantly agitated, and apply the liquid with a spraying nozzle fitted to a syringe. Two applications may be found necessary. You could also collect the caterpillars quite easily by jarring the branches over an inverted umbrella.

Cucumber Gumming: *P. F.* The fruit contains no trace of fungus disease. The injury has been caused by some error of culture, and most probably by an excess of moisture causing a water-logged condition in the soil. Afford increased ventilation to the house in order that the air may circulate more freely.

Double-spathed Arum: *W. P.* The example sent by *J. T. L.* (see p. 292 in the last issue) was Richardia Elliottiana. The abnormality is as common in this species as in R. africana, but you must remember that this latter plant is very much more extensively grown in gardens than R. Elliottiana. It is probably due to intensive culture.

Figs Diseased: *G. S.* The Figs are attacked by Botrytis cinerea, a fungus that can only attack plants in the presence of an excess of moisture. Burn all the affected fruits and afford increased ventilation to the house in which the trees are growing. The insect you indicate is certainly not the Peach weevil, but probably some harmless beetle. If you will send us a specimen we will endeavour to name the creature for you.

Gardening in Australia or New Zealand: *W. R.* We have shown your letter to Mr. James McIndoe, who, having visited the Antipodes, has especially studied the conditions of horticulture from the point of view of the private gardener. Mr. McIndoe states that anyone emigrating to Australia or New Zealand in the hope of obtaining a good situation as head gardener there incurs a great risk of being disappointed, no matter how good his testimonials may be. Large private garden establishments are few. With regard to public parks, a stranger may have to wait for years before he attains a superintendent's position. The gardeners in demand are good spademen and handy men who are not particular in turning their hands to anything that comes in the way. Such men have no difficulty in getting situations in the neighbourhood of large towns at wages ranging from 40s. to 50s. per week.

Goose-tongue: *J. Y D.* This popular name is applied to two plants, viz.: Galium Aperine and Achillea Ptarmica.

Grape Vine: *T. G.* There is no disease present caused by fungi or insects. Such injury to the foliage is very frequent near the top of a vinery, and is due to the dryness and comparative impurity of the air. Top ventilation, judiciously applied, will put the matter right

Maggots in Soil: *C. Weaver.* These are the larvæ of a two-winged fly belonging to the genus Bibio. They are often found in the earth in great numbers feeding upon decayed vegetable matter, but are apparently quite harmless to cultivated plants.

Melon Plant: *W. P.* Gumming in Melons and Cucumbers is generally the outcome of an excess of nitrogenous manure. When the plants are almost fully grown there is but little chance of remedying the injury.

Names of Plants: *E. S.* 1, Azara microphylla; 2, Phlox subulata; 3, Iberis sempervirens; 4, Alyssum sp. (cannot name more definitely in the absence of flowers); 5, Saxifraga cordifolia; 6, Helianthemum vulgare.—*Alpine.* 1, Erysimum ochroleucum; 2, Salix serpyllifolia; 3, Aubrietia deltoidea "Dr. Mules"; 4, Aubrietia deltoidea var.; 5, Saxifraga muscoides var. atropurpurea; 6, Berberis Darwinii.—*A. H.* Fritillaria pyrenaica.—*T. D.* Acer rubrum.—*Derwydd.* 1, Nephrolepis tuberosa; 2, Asplenium bulbiferum biforme; 3, Streptosolen Jamesonii; 4, Berberis stenophylla; 5, Cydonia (Pyrus) Maulei; 6, C. japonica.—*J. E.* 1, Pelargonium Lucie Lemoine; 2, flowers dropped; 3, P. Triomphe de St. Amande; 4, P. Rose Celestial; 5, P. Mme. Thibaut; 6, Rose Mrs. W. J. Grant.—*Vitis.* 1, Orobus vernus; 2, Epimedium Perralderianum; 3, Trollius asiaticus; 4, Corydalis nobilis; 5, Fritillaria meleagris alba; 6, Diplacus glutinosus.—*H. R.* 1, Calanthe veratrifolia; 2, Cœlogyne ochracea; 4, Isochilus linearis; 5, Oncidium Harrisonianum; 6, Odontoglossum Lindleyanum.—*L. H., Han's.* 1, Cardamine pratensis; 2, Helxine Solieroli; 3, Epimedium diphyllum; 4, Oxalis rosea.—*W. E. S.* 1, Cattleya Mossiæ; 2, Cattleya Mendelii; 3, Cypripedium Harrisianum superbum; 4, Odontoglossum Andersonianum.—*W. P.*—Dendrobium Loddigesii, commonly known in gardens as Dendrobium pulchellum.—*K. A* Litobrochia biaurita.—*C. H.* Heuchera sanguinea.—*H. M.* We are unable to identify the plant from such a specimen.

Nectarine Tree: *J. M.* The injury is caused by the air being too dry when the young shoots are growing. The result being the shoots lose too much moisture on the warmest side, and the skin contracts and dies.

Peach Tree: *H. W.* The fruit shows symptoms of gumming. If a pound of common salt be sprinkled on the soil round the root in such cases, at intervals throughout the year, it often checks the disease.

LILIUM JAPONICUM (SYN. L. KRAMERI); FLOWERS WHITE, TINGED WITH PURPLE ON THE OUTSIDE.

Printed by Temple Press Ltd., London, E.C.

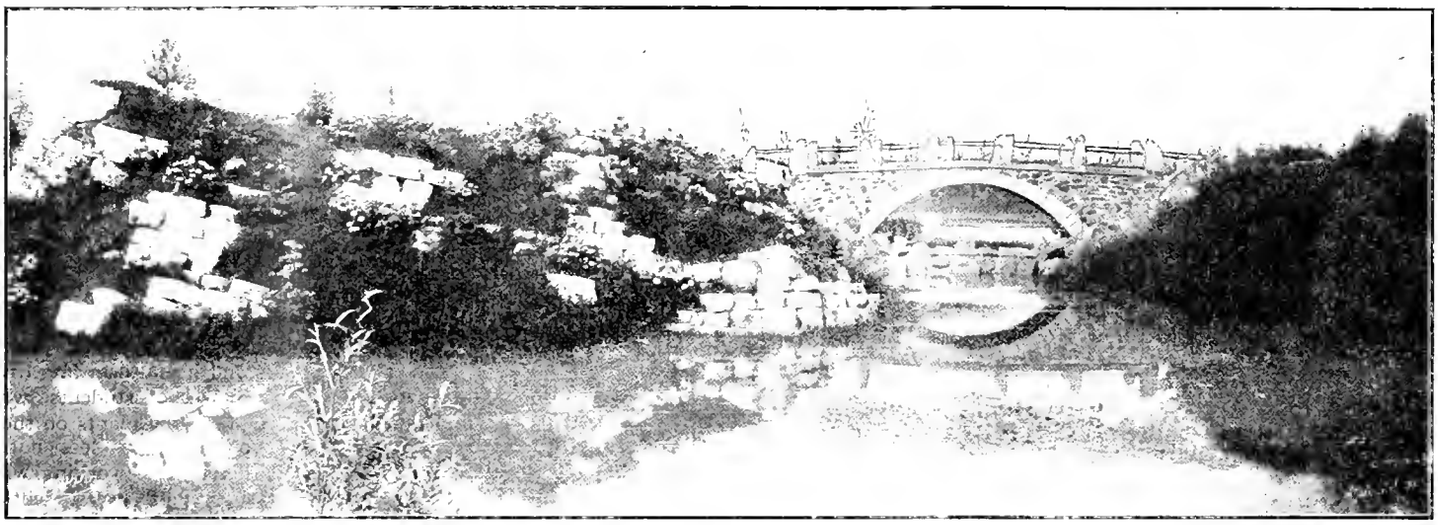

Fig. 145. View of bridge spanning the lake in the Berlin Botanical Gardens.

up the vegetation becomes gradually dwarfed until the summit is reached, where only the smallest of Alpines are to be seen nestling between the stones, or lying flat on an otherwise naked surface. The art of the gardener is needed to maintain something like the natural proportions, otherwise a full-grown Larch would overtop the highest points. This is accomplished by simply cutting out the trees when they get too large, and substituting smaller ones. The most imposing of these ranges is that of the Swiss Alps, the Matterhorn, Mont Blanc, and the other noted peaks being there represented. Each range stands out quite clearly from the rest, and they have all been kept as near as possible to scale. Consequently Mount Everest and Kanchanjunga, in the Himalayas, are the highest points of all. Torrent and stream flow down the mountains, across and under the rocky paths, over falls, and into lakes in a way that should delight the Japanese artist. While there are plenty of paths to enable the visitor to inspect every feature of the Alpinum, they are so cleverly placed and constructed as to be quite unnoticeable.

To keep this department supplied with plants to replace those that die, a large nursery with unheated houses and frames is maintained. Even a collection of mosses is grown for the purpose of showing them as they occur in nature. They are grown on tiles, bits of stone, pieces of wood, &c., in a small house devoted specially to them.

A special department is devoted to hardy plants from North America and Japan. This includes a little mountain range, and the plants are grouped geographically, quite an interesting collection being displayed. Another feature of interest, to the German student at any rate, is an assortment of trees, &c., planted and arranged as in a German wood. As someone observed: "It is a chunk of wood cut out of a German forest to show what the vegetation is like."

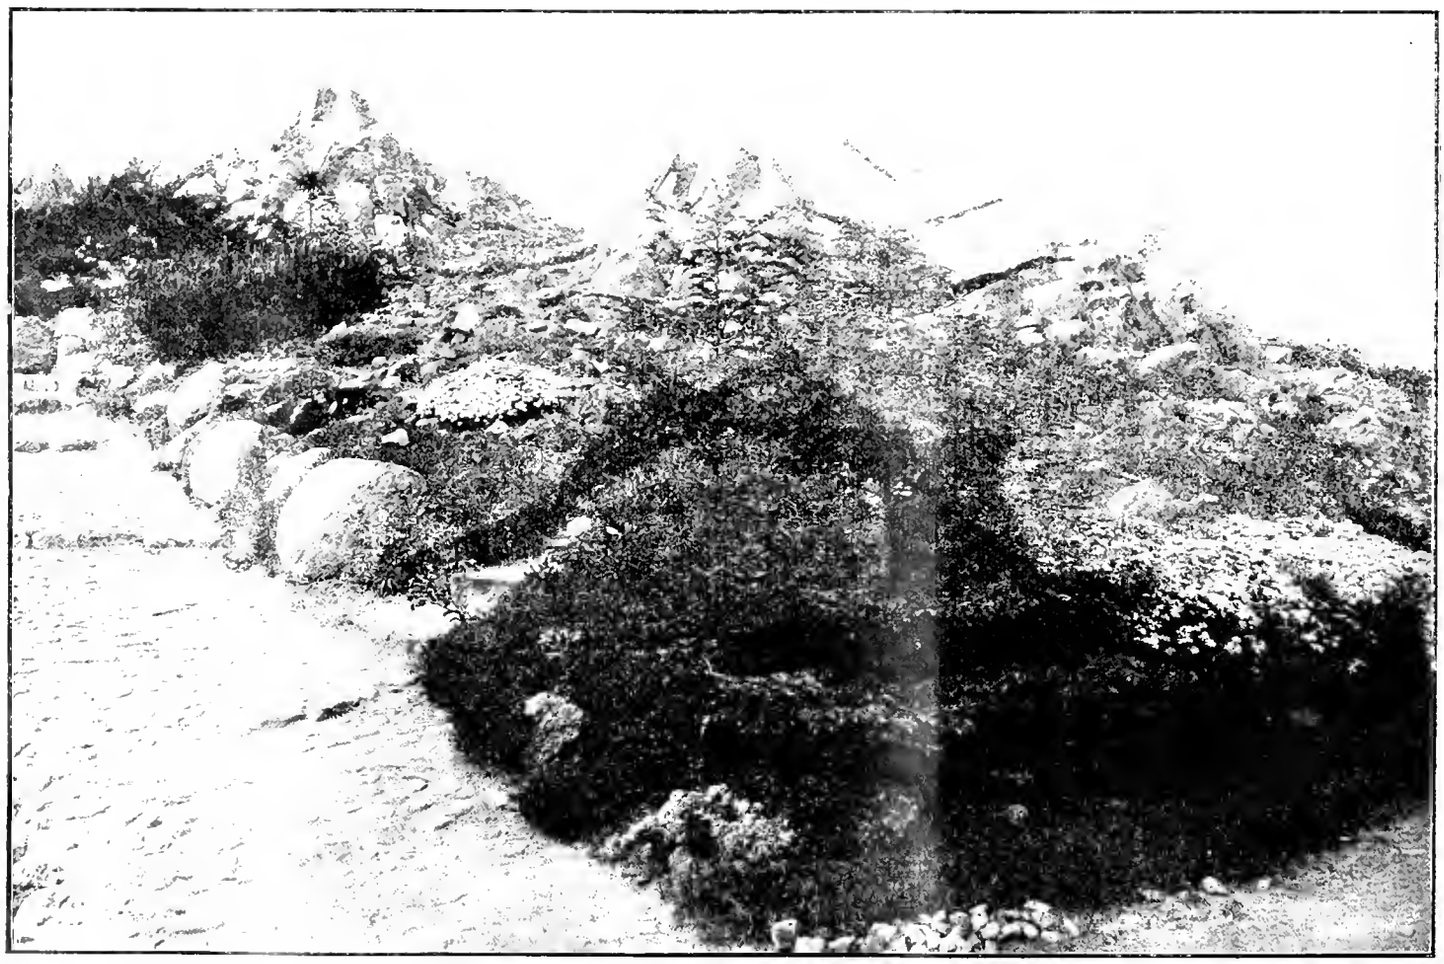

Fig. 146.—Portion of the rockery in the Berlin Botanical Gardens.

There is no decorative department worth speaking of, a few formal beds near the two principal entrances representing the sole attempt at flower gardening. Mention may also be made of a formal Italian garden, which in my opinion is singularly out of place, although perhaps the intention is to show a sample of what is considered art in the garden. *J. G. W.*

(To be continued.)

NURSERY NOTES.

DAFFODILS AT LOWDHAM NURSERIES.

A visit to Messrs. J. R. Pearson and Sons' Nurseries at Chilwell is always interesting, and especially when the Daffodils are in flower. This season we have experienced the worst weather in spring I ever remember, but the Narcissi have withstood the ordeal successfully, and they are in a better condition at these nurseries than ours at Belvoir Castle, although the climatic conditions are almost the same, the two places being only 15 miles apart. The soil in both cases is a retentive and deep one, but the trade grower must have good shaped bulbs for sale, and he is therefore bound to re-plant every year, or at the latest every second year; the private grower, however, does not cater for the sale of his bulbs, and therefore does not practise frequent transplanting. This shifting, however, enables the plants to better withstand severe weather, because the flower stems are developed more stiffly, and do not become so drawn, and in many instances the flowers are larger.

Amongst the new varieties to be seen at Lowdham is Florence Pearson; this belongs to the Ajax section, the flowers being white faintly tinged with cream. Although large, they are of refined form and appearance, while the growth of the plant is remarkably vigorous and free.

Hon. Mrs. Franklin has a white perianth and a centre of pale lemon colour; this is also a strong growing variety, with flowers of excellent form and colour. Another of merit is that named after Mrs. Bretland Farmer; this is also a very large flower of the Ajax type; the perianth is pure white, and it has a long, straight trumpet.

Pearl of Kent is also a large pure white, trumpet variety. The corona is much reflexed, being of good substance, and splendid in form; it is quite one of the best of all the race. Weardale Perfection is a bicolor variety with a very large pale yellow trumpet. At Chilwell a large stock of this kind is grown; the plants were flowering well, and growing vigorously. King Alfred is a favourite with all who know it, for the flowers are large, of a beautiful rich yellow colour, and are developed high above the foliage. The whole growth is vigorous and healthy, and it is certainly one of the best Daffodils raised. Glory of Noordwijk is a large bicolor variety, vigorous in growth, and with distinct and good flowers.

A vigorous, free-flowering variety is Golden Bell, the perianth being pale yellow, and trumpet of a deeper yellow. The season of flowering is earlier than in many other varieties. Lord Roberts has flowers of large size; the perianth is yellow, with a deeper shade in the trumpet. It is a strong growing variety, having flowers of good form.

Alert belongs to the "Tenby" class, and, in common with N. obvallaris, it flowers early. Alert has much vigour, and grows where the older variety fails. Apricot is an interesting variety, as it is the first of a new race possessing a reddish colour in the trumpet. The plant is not a vigorous grower, and the flowers are small.

Varieties with medium and small corollas include Lowdham Beauty. This variety has white segments that are broad and flat, and in the centre is a deep, wide, pale yellow cup that changes to white. The growth is extremely vigorous, and the plant is one of the best of its section.

Marguerite Durand is similar in form to the last-named variety, but the flowers open white and change to pale yellow. This also has a strong constitution.

Branston is a white sport from the well-known Barrii conspicua, and possesses all the good qualities of that excellent variety, with its pretty red eye; a large breadth of this Daffodil was in flower at the time of my visit.

Gipsy Queen has a large flower and broad cup: the segments are creamy-white, the cup yellow, edged with orange. Horace, one of the Poeticus varieties, has large, pure white segments, which open quite flat, and a deep red eye. The habit is tall and robust. Heroine is also a white variety, with a broad cup that is greenish-yellow and edged with red. Gloria Mundi is not a new variety, but it is one of the choicest. In common with many other gardeners, I find this variety a difficult one to keep in health, but it was growing freely at the Lowdham Nurseries.

Lady M. Boscawen is a suitable variety, either for the garden or for furnishing cut blooms. It may best be described as a giant Nelsonii major; the perianth is pure white, and the long, straight cup lemon-yellow.

Scarlet Eye is a pleasing variety, having a perianth of pure white, the segments forming a star; the cup is an intense scarlet colour. A good breadth of this plant was in flower, and amongst other varieties it had a very distinct appearance.

Scarletta is a somewhat similar flower to the preceding variety, but the perianth is slightly tinted with lemon, which to some persons would appear a desirable addition. White Lady has a white perianth, the segments being large and flat; the cup is large and coloured lemon-yellow. This variety is valuable to florists for making floral decorations.

Prima Donna is a remarkable flower, unlike any other variety. The perianth is flat, with broad, overlapping segments; the cup is straw coloured, with a red edge. The flower is 4 inches in diameter, and the cup measures 1¼ inch across. In a collection containing about 50 of the best kinds in vases, this was the one which caught the eye first. The plant is apparently of a good constitution.

In addition to the above varieties, I was shown many unnamed seedlings of promise. Mr. J. D. Pearson is well known as an enthusiastic cultivator and a raiser of new varieties, including Florence Pearson, Lowdham Beauty, and Marguerite Durand. Amongst the older varieties, I especially noted the following: Madame de Graaff, of which a thousand bulbs were in flower, forming a grand display; Glory of Leyden; J. B. M. Camm, still one of the most beautiful Daffodils grown; it stands bad weather well, and is later in flowering than many; Maximus, a species which does not succeed on light soils, but the plants were doing well in these nurseries; Duchess of Westminster, still one of the best "whites"; Flora Wilson, a sweetly-scented Daffodil; Lucifer, with long white segments and a bright orange-coloured cup; Lulworth, with segments of creamy-white and a cup of orange-scarlet; Sir Watkin (a large stock of this well-known variety is grown); Argent, after the style of the Phœnix varieties, but of much stronger growth, having flowers that remain erect. The collection occupies 3 acres of ground. Some beds of Muscari conicum "Heavenly Blue" growing near the Daffodils gave a beautiful contrast of colour. *W. H. Divers, Belvoir Castle Gardens, Grantham.*

DAFFODILS AT SURBITON.

It has been our pleasure for several years to visit the nurseries of Messrs. Barr & Sons, at Surbiton, to see the Daffodils in flower, but we have never until this season received the invitation so late as in May. The flowers have bloomed abnormally late, and small wonder, when one remembers the arctic weather that has characterised the spring of 1908. Not only did the cold retard the flowering of the bulbs, but the heavy rains of April caught them when in bloom, and then, when a few warm days did appear the flowers were quickly over. Thus, in a measure, we were disappointed, but these flowers are cultivated on such a large scale at Surbiton that there still remained abundant material of interest, and it was an easy task to find some late flowers of the majority of the varieties. In addition, a late duplicate planting of all the best early kinds is practised by Messrs Barr in order to furnish material for hybridising with later-blooming sorts. The weather on the occasion of our visit was glorious, and in addition to the Daffodils, the great breadths of May-flowering Tulips, with Irises of the pumila type, Polyanthuses, Ranunculuses, and a host of other hardy spring flowers made a beautiful picture. The principal entrance to the fields of Daffodils is through a small rock-garden, to which we have often referred in former notes, but we have never before seen it so prettily furnished with flowers, including Spiræas, Cydonias, Aubrietias, Muscaris, Drabas, Primulas, Jonquils, Fritillarias, and similar subjects, with dwarf shrubs and Conifers interspersed.

Of varieties of Daffodils it may be said that their number is almost endless, and Messrs Barr's latest list enumerates nearly 400 distinct sorts, which, of course, does not represent all the varieties in commerce, although most of the best varieties are included in it. The first of which we have note is the variety named Evelyn Hodge. It was raised from N. montanus × N. biflorus, and possesses a white perianth set off with a small, pale-coloured corona.

Merry Maid was raised at Surbiton in 1907. This is a tall, late-flowering Narcissus of the Barrii section, with a pure-white perianth, tapering in its segments, and crowned by a corona that is yellow and tipped with orange. Bianca is a Leedsii Daffodil that has its white perianth set off with a lemon-coloured cup, the latter being prettily fluted. Agnes Harvey is a variety of rather delicate growth; this is another of the Leedsii section. It often develops two or more blooms on a scape, and is to be recommended for its charming form. Egret has the large, flattened corona of the Englehearti section, to which it belongs, and beneath its crown the broad, white segments form a perianth of the finest type.

Amongst the best of recently-raised trumpet Daffodils is C. H. Curtis. This is a bold flower having a handsome corona that recurves somewhat at the mouth. The perianth is a deep shade of yellow, but not so intense as the golden cup. Another flower of the C. H. Curtis type is George Philip Haydon. The mouth of the trumpet also expands in this variety, and it is finely fluted, but the colouring in both perianth and cup is paler than in the flower named after C. H. Curtis, and its appearance is stiffer. Both varieties were raised in 1905 by the Rev. G. P. Haydon. Knight Errant is another of Mr. Haydon's raising: this is also a trumpet Daffodil, but with white perianth and sulphur-coloured trumpet. Its parents were probably Mad. Plemp and Cernuus. A beautiful white Daffodil is seen in Eileen Mitchell, and, as one of its parents was N. triandrus, the character of producing more than one flower on a scape is perpetuated in the hybrid, and twin

flowers are common. The white of its floral parts is of remarkable purity, and the habit is very graceful. The variety Beauty is not new, but it cannot be passed over without comment. It is a fine, bold flower of the Incomparabilis type, with a pale yellow perianth and a large cup that is tinged with orange. This variety may be recommended for any of the purposes to which the Daffodil is utilised, and is especially valuable for cutting. It is one of the cheapest of Daffodils, and should be largely grown wherever these beautiful spring flowers are planted. White Lady is characterised by a broad perianth of beautiful form the cup being slightly tinged with yellow. It has the advantage of being a free bloomer, and deserves inclusion in a selection of the best varieties. Silver Moon, Sylvia, May Dew, and Fantasie are varieties of a similar type, and valuable for naturalising in grass and woodlands. All these, save Sylvia, were raised at Surbiton last year. They bear their inflorescences well aloft, and have starry, white perianths. Rosalind is one of the Dolly-Cup Daffodils, one of the best in its section. The cup is bright yellow, and it is tinged with scarlet. The habit is very robust. Autocrat is a choice flower of the Incomparabilis type, one of the cheapest of Daffodils to purchase. Una is remarkable in its foliage, which appears to droop. The perianth is creamy-white, its bold corona being suffused with citron colour, which deepens to apricot at the edge. A fine star-shaped Daffodil is the variety named after Frank Miles; it is to be recommended as a late variety for planting in grass land. The beautiful white trumpet Daffodil Alice Knights was past its best condition, but enough remained to show what a lovely flower it is. This may be regarded as the best of the early white trumpet section. Czarina, a giant Leedsii, is certainly among the finest of its class; it is quite new. The yellow trumpet Daffodil Lord Roberts is a flower of large size, massive in both corona and perianth, which are coloured golden-yellow. This variety was raised at Surbiton. Our list is still incomplete, but we have no space to describe the many other varieties of which we made note, including Loveliness, Monarch, Gloria Mundi, Duchess of Westminster, Cloth of Gold, Cassandra, Blackwell, Ariadne, Cygnet, Glory of Leiden, Hamlet, Lady Margaret Boscawen, Janet Image, Peter Barr, Salmonetta, Queen Christina, Stella superba, Victoria, Weardale Perfection, and Blood Orange. Most of these are well-known varieties, and all are worthy of a place in a collection of the best kinds.

NEW OR NOTEWORTHY PLANTS.

ODONTOGLOSSUM × VULCAN.

(VUYLSTEKEI × CRISPUM.)

WHEN at Bruges on May 2, 1908, I saw the two first plants in bloom of this new hybrid, which was raised by Messrs. Sander. The plants varied considerably, but the better variety is a good addition to the already numerous progeny that have been raised from O. × Vuylstekei.

The sepals and petals are both grounded with brownish rose; and upon the sepals heavy brown blotches occupy almost the whole surface, the petals having in addition a pretty margin with white marbling at the base.

The lip is intermediate in form between the parents; it is white, heavily blotched over almost all its area with red-brown. The column is heavily coloured with purplish-brown, indicating that the column of the male parent was a very handsome one.

This plant will make a fine female parent whereon to cross any O. Harryanum hybrid that contains a large amount of rose colouration. *de B. Crawshay, Rosefield, Sevenoaks, May 12, 1908.*

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM LAIRESSEI

(O. CERVANTESII ROSEUM × O. EDWARDII).

OUR illustration (fig. 147) represents a spray of this pretty hybrid Odontoglossum taken from a plant which recently flowered in Messrs. Sander & Sons' collection at St. Albans. The blooms are pale pink, with the inner parts of the segments purplish-violet, almost of the same tint as that of Odontoglossum Edwardii, the male parent of O. Lairessei, which first flowered with the raiser, M. A. de Lairesse, of Liege, early in 1905. It is difficult to conceive two more widely separated species than the dwarf O. Cervantesii and the large-growing O. Edwardii, which latter has very tall branched spikes of violet-purple flowers, and the plant under notice, which is fairly intermediate in every respect between the two species used in its production.

Odontonia Lairesseæ (see fig. 148), another very interesting cross made by M. A. de Lairesse between Miltonia Warsewiczii and Odontoglossum crispum, was recently seen in Messrs. Sander & Sons' nurseries at Bruges, with three fine spikes of blush-white flowers prettily marked with rose colour.

FIG. 147.—ODONTOGLOSSUM LAIRESSEI: FLOWERS WHITE, MARKED WITH ROSE COLOUR.

LÆLIO-CATTLEYA MARLBURIA

(LÆLIA BOOTHIANA × CATTLEYA SCHRODERÆ).

FLOWER of a pretty hybrid raised from the above-mentioned cross is sent by the raiser, Eustace F. Clark, Esq., Chamonix, Teignmouth. In its fine shape it resembles one of the light forms of L.-C. Fascinator (L. purpurata × C. Schroderæ), but evidence of L. Boothiana (commonly known in gardens as Cattleya lobata) appears in the lilac-tinted sepals and petals, and the distinct veining of the light purplish-rose front of the lip. The base of the lip is white, the disc but faintly tinged with yellow, and the fragrance of C. Schroderæ can be detected in the hybrid. It is a very good and delicately-coloured flower and a distinct improvement on Lælia Boothiana.

CYPRIPEDIUM (PHRAGMOPEDILUM) LINDLEYANUM.

A STOUT-BRANCHED inflorescence of this remarkable species, 5½ feet in height, comes from the Royal Botanic Gardens, Glasnevin, Dublin, where it must have been a fine object rising above the broad, shining green leaves which render the plant ornamental even when not in flower. The numerous flowers, which are about 2 inches across, have a tawny yellow ground colour tinged with and striped with red-brown, the wavy margins of the sepals and petals being ciliate and the sepals downy on the reverse side. It is a native of British Guiana, and P. Sargentianum, of Pernambuco, is closely allied.

NOTES FROM A "FRENCH" GARDEN.

DURING the past two weeks we have formed ridges of dry manure 5 feet apart, and on the end of each ridge have been placed the lights that formerly covered the Carrots and Cauliflowers. Trenches were next dug for the planting of Melons, the hole being made 2 feet wide by 1 foot deep. This we filled with the dry manure, to which had been added one-third its bulk of fresh manure. As soon as each bed is completed the frames are removed from the Carrots and placed on the new bed. The soil removed from the following trench is spread evenly in the frames, care being taken to place some rich soil in the centre of the light wherein to plant the Melons. When planting is finished, the lights are placed on the frames, and the plants are then ready for forcing. The work is proceeded with in the same manner until the whole of the ground allotted for the culture of Melons is planted.

The Melons are well established in pots, and have been stopped to the second leaf. These plants are set in their final quarters two or three days after the bed has been made. Before planting the Melons, all shoots growing at the base of the Cotyledons, and any close to the main shoots, must be cut off with a sharp knife. This precaution is essential, as these shoots often rot and cause the main stem to decay. When the plants are set, a slight watering is given, which is sufficient for two or three weeks. During the first week of planting the Melons must be shaded from bright sunshine with mats, but when they are established this shading is not necessary.

The Melons planted at the end of March have been benefited by the warmer weather of the past week, and their young leaves, which curled during the inclement weather at the end of April, have again assumed a healthy appearance. They have recently been watered. When Melons require a thorough watering the application is spread over two days, in order that too great a quantity of cold water be not applied at once, and thus cause a check to the young roots.

We are making our final sowing of Melons for the season, the varieties being Improved Prescott, Cantaloup, and a lesser quantity of "Kroumir." Plants of the latter variety are very hardy and strong in growth, and in

great demand amongst the French working classes. We allow two fruits to each plant instead of one, as is the case in the Cantaloup type.

The Carrots and Cauliflowers are now in the open; great care is taken in the watering of these vegetables, and it is done at regular intervals. We generally use 250 gallons of water per bed of 15 lights, three or four times a week, according to the weather. This is the season when nurserymen or gardeners will appreciate a well-laid irrigation system where they can obtain a supply of 2,500 gallons of water per hour.

Our Carrots will be ready for marketing in a fortnight. They are of the "Carrot Bellot" variety, a cross between the Early Parisian and the Half Horn. It is not so early as its first-named parent, but it is of a much bigger size, and consequently more valuable.

Next week we shall sow a batch of Endive "La Rouennaise" to take the place of the Cauliflowers at present growing amongst the Carrots. We sow them on a specially prepared hot-bed. The seeds are sown thinly, being spread broadcast in the frame. The seedlings are planted directly into their final quarters.

Our second batch of Cos Lettuces under the cloches is ready for the market. The plants have suffered somewhat from the recent wet and dull weather.

We are now cutting "Passion" Lettuces, which have been grown entirely in the open since January 20. They were sown in October and cultivated during the first part of the winter under cloches. They have received more ventilation than the other varieties, for they are stronger and hardier in growth. We planted them out at the end of January at distances of 10 inches apart. *Paul Aquatias, Mayland, May 13.*

VEGETABLES.

RUNNER BEANS.

Many improved varieties of Runner Beans have been presented to the public during the past few years, and improvement is also to be noticed in the dwarf-growing varieties, and those that are intermediate between the runner and the dwarf kinds. A great gain has been made in the shape of the pod which, in these improved kinds, is shapely, long, has small seeds, and is of excellent edible quality. The plants are, in addition, more fruitful than the older kinds. A shapely pod can be easily prepared for the table, and several of these newer varieties are almost "stringless" in a young state. The new climbing French Beans are a distinct gain to the cultivators who have not a large space at their disposal, for the longer growth enables the plants to bear continuously until the end of the summer, and three or four times the quantity of Beans can be had from them than is produced by plants of the dwarf section. It is the practice in this country to cook Beans when they are almost mature, but their flavour is delicious when cooked whole in a young state, and by this system of serving them there is no waste. By gathering the Beans when young, the plants are enabled to produce other pods freely, and there is no expenditure of the plant energies on the formation of seeds.

Beans require a rich rooting medium and abundant supplies of moisture during hot weather, especially when the plants are in full bearing. On heavy, clayey soils I have obtained excellent results by growing Beans in trenches. No great gain is made in sowing Beans too early, as the plants, being tender, are readily injured by cold or excessive moisture. Their season of fruiting may be hastened by sowing them under glass and planting them out at the end of May. I advise two sowings of the climbing French Bean, the second one to follow at an interval of six weeks or two months. These later-sown plants will carry on the supply until the autumn frosts cut down the plants; whilst the earlier batch can be cleared away in time to make room for a winter vegetable crop. Amongst the best of the Runner Beans are the following: Prize-winner: This is a very distinct Bean and a valuable one for exhibition purposes; the pods, even when young, often measure 1 foot in length; they are tender, and are borne profusely; the variety has received a First-Class Certificate from the Fruit and Vegetable Committee of the Royal Horticultural Society. Best of All is another fine Runner Bean, equally valuable as an exhibition variety; the growth is robust, and its fruiting is prolific, the pods being produced in large clusters; its edible qualities are devoid of all coarseness. Both these varieties are very distinct from the old Scarlet Runner Bean, and they well merit a trial in gardens. I was last season much impressed with the qualities of the new Scarlet Runner Bean "The Emperor." This is a prolific cropper, producing a finely-shaped pod 12 to 15 inches in length, of a pleasing dark green colour. The long, straight pods are suitable for exhibition purposes, and a good dish of this Bean is a feature in any exhibit of vegetables. Apart from all these qualities, it makes a fine dish for the table, as the flavour is delicious, and it is free from coarseness of texture. Another fine Runner Bean is Jubilee Runner. The Beans are

Fig. 148.—Odontonia × Lairesseæ.

See p. 328.

produced in great clusters, and are even larger than those of The Emperor, being thicker and more fleshy.

These remarks on Runner Beans would be incomplete without reference to Hackwood Park Success, raised by Mr Bowerman of that place. The long handsome pods are quite straight, from 9 to 10 inches in length, and of the best edible quality. The pods are produced in clusters. I have counted more than 30 in various stages of growth on a single raceme. This variety is one of the earliest of Runner Beans to fruit, and, in every respect, it is a great advance on the old Scarlet Runner.

The newer climbing French Beans include Veitch's Climbing, and Tender and True. The growths need only stakes from 5 to 6 feet in length, and they are capable of furnishing a supply of Beans until they are cut down by frost. Both are free-bearing, and the Beans are excellent for consumption in a young state. Excelsior is slightly taller than these two, which may be considered an improvement, and it is equally prolific as those just named. Epicure is distinct from the three I have mentioned; the pods are very thick and fleshy, and are suitable for cooking whole, owing to the seeds being very small. Princess of Wales reaches about 5 feet in height; this also is a great cropper, the pods being of first-class flavour. Earliest of All is valuable for its early cropping; the pods are fleshy and excellent when cooked whole. Among the new type of "stringless" Beans may be mentioned Carter's July and Successor. The growths of the first-named variety are 3 or 4 feet in height, and produce long, straight, stringless Beans. It is a free cropper, and provides a supply of Beans early. Successor is a later Bean, but very prolific, and of first-class quality. *G. Wythes.*

COLONIAL NOTE.

YLANG-YLANG CULTIVATION.

The flowers of this tree give, on distillation, an essential oil, very valuable for perfumery purposes. The tree belongs to the same family as the Sour sop (Anonaceæ), and appears to flourish in many of the botanic gardens of the West Indies, where specimens have been planted.

The tree is largely grown in Reunion for the production of its essential oil, the price of which has steadily increased in value of late years. It is also cultivated in the Philippine Islands.

Recent U.S. consular reports from Cochin China state that planting of the Ylang-ylang has been taken in hand on several estates in the province of Bienhoa with satisfactory results. The high price obtained for the essence makes the cultivation highly remunerative. It is stated officially that two acres planted with 300 trees may give 6,500 lbs. of flowers, which would yield at least 33 lbs. of essence.

In the past there has apparently been some confusion as to the proper botanic name of the Ylang-ylang. It has been referred to as Artabotrys odoratissimus and Unona odorata. It is evident, however, that the correct name is Cananga odorata.

LEMON GRASSES IN CEYLON.

Lemon grass is largely grown for its oil in Ceylon. It does not seem to be particular as to soil or situation, and will grow at any elevation up to 1,600 feet. The soil that gives the best returns, however, appears to be a sandy loam.

Lemon grass is usually propagated by offsets from clumps of mature grass. The best results are obtained from clumps two or three years old. The stools are divided into slips and planted into holes at distances of 2 or 3 feet apart. After planting, the soil should be trodden down firmly around the plants. Necessary weeding operations should be carried out at least twice a year.

In the cultivation of this crop little or no expenditure need be made in the purchase of manure. An occasional application of cattle dung, however, is said to have good results, and after distillation of the essential oil, the grass may be returned to the ground as a mulch. In Ceylon a first cutting of grass is made about nine months after planting. Two or three cuttings a year can be made. Replanting is necessary after the third year.

The oil is generally distilled directly the grass has been cut, but it is stated that better results are obtained by keeping the grass for a day before commencing this operation. The process of distillation, although very simple, takes four or five hours to complete. After distillation, the crude oil is filtered and then run into bottles or casks ready for the market. The yield of oil varies greatly, sometimes amounting to 0·2 per cent. of the weight of the grass. A good yield is about 100 quarts, or 4,000 fluid ounces per acre. At 6d. per ounce, this represents a return of £100 per acre.

Lemon grass oil is generally employed in the perfuming of scented soaps and pomades. It is also largely used in the adulteration of verbena oil. The product has largely increased in value of late years, and in Ceylon a price of from 6d. to 8d. an ounce can be relied on. A sample of oil sent from Montserrat was valued by London brokers at 4½d. per ounce, and it was stated that there would be no difficulty in disposing of at least 500 lbs. of the product. *Agricultural News, April 18, 1908.*

NOTICES OF BOOKS.

* "THE VEGETABLE GROWERS' GUIDE."

THE authors of this work, of which the first volume is now before us, have embarked on a large task, and they are fully aware of its magnitude, as the preface and introduction to the work abundantly prove. In fact, the treatise, for it is nothing short of this, is so planned as to tell all that is worth knowing about vegetables. It will be readily admitted by all who peruse the pages that the authors have gone a long way in the direction of substantiating their claims to completeness, even though the reader may not see "eye to eye" with them on all the points they raise—and settle. But they speak with considerable authority bred of long experience of vegetable growing under diverse conditions. The volume opens with discussions on the formation, and the maintenance of the kitchen garden, and the whole is treated in a very practical spirit. We venture, however, to suggest that the diagram on p. 21, showing how a system of drainage should be laid, is not planned in accordance with the best principles. The main drain is carried obliquely across parallel straight rows of side drains, with the result that all the laterals on one side of the main must always enter it at more than a right angle. The remarks on manures are sensible and sound; whilst properly advocating the use of natural manure as a chief means of building up the necessary humus, the utility of suitably-chosen chemical fertilisers is explained.

Passing to the consideration of the growing of the vegetables themselves, each kind is fully treated, the cultural details are exhaustive, and much critical information is given as to the value of different varieties of each vegetable. The principal pests, both animal and vegetable, are also described, and in many cases figured, and this information will be greatly valued by the intelligent gardener who is everywhere taking a wider and more scientific interest in all that appertains to the welfare of his crops.

A feature of the book which will not only prove useful at the present time, but at a future period will still be valuable from the historical point of view, lies in the financial estimates, both of the cost of growing and of the profit obtainable from the different vegetable crops under garden cultivation.

Whilst the over-specialising on "exhibition" produce is deprecated, the authors adopt a reasonable and well-balanced attitude towards this question. For, whilst there can be no doubt that the growing for exhibition purposes may, and sometimes does, lead to the abandoning of the really good for the apparently magnificent, it is equally certain that the competition afforded by shows serves as an excellent stimulus, and tends to check slackness or contentment with mediocrity on the part of the gardener.

We are glad to congratulate the authors on the production of the first instalment of so fine a work, and we doubt not that all who are interested in the cultivation of garden produce will look forward with interest to the completion of the book. Its other merits are enhanced by the numerous figures and coloured plates, and if the former are sometimes a little rough, they, at any rate, serve their purpose. The publishers also deserve praise for the general excellence of the printing and other technical accessories of a book which will deservedly take its place as a standard work on the subject of vegetable culture, which is rapidly becoming of greater importance in this country.

* *The Vegetable Growers' Guide*, by John Wright, V.M.H., and Horace J. Wright, with 30 coloured plates and upwards of 200 diagrammatic drawings; Vol. I. London: Virtue & Co.

The Week's Work.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Major G. L. HOLFORD, C.V.O., C.I.E., Westonbirt, Gloucestershire.

Oncidium macranthum.—This species is of comparatively easy culture, if afforded a cool, intermediate temperature and protected from strong sunshine in the summer months. The flower scapes are now nearly developed. They are exceedingly large when compared with the size of the pseudo-bulbs which produce them, and they necessarily exhaust the plant to a considerable extent. It will, therefore, be seen that the plants should not be allowed to flower before they have become strong specimens. O. macranthum produces strong, thick roots which should be carefully protected at all times, never allowing them to suffer from drought at any season. The plants dislike to have their roots disturbed. Therefore, re-potting should only be carried out when it appears to be absolutely necessary, but in cases where the plants need it the operation may be carried out at any time when the young growths are seen to be producing fresh roots. When re-potting, let ample rooting space be provided for each plant, and the base of the plant be set rather low in the pot, filling up to and around it with crocks and charcoal, for drainage purposes. For the rooting medium employ Osmunda fibre, Polypodium fibre, and Sphagnum-moss in equal parts, using these ingredients in a rough state and mixing with them some crushed crocks and charcoal. Make the material moderately firm about the roots. After this has been done place some clean, hand-picked Sphagnum-moss over the surface. Owing to the climbing habit of this species, the young roots of established plants are often produced some little distance above the surface of the compost. In such cases a little material should be placed in such a position that these roots may reach it, and thus be conducted to the compost beneath. Should they remain exposed they would be the more liable to injury from insects.

Cœlogyne cristata and its varieties.—Since these plants flowered a very moderate supply of water at the roots has sufficed for their requirements. During that period of partial rest they have recovered from the strain imposed by the flowering, and the shrivelled pseudo-bulbs have regained their plumpness. But growth having commenced, the amount of water applied to the roots should be gradually increased, until it is seen that the new pseudo-bulbs have commenced to form, when the supply should be again increased until the pseudo-bulbs have completed their development. Established plants in a healthy condition should be kept in a light position in a freely ventilated atmosphere of intermediate heat, and the surroundings should be maintained in a moist state by frequently damping the stages and other surfaces in the house. The plants may also be sprayed overhead whenever the weather is bright. An examination should now be made of these Cœlogynes to ascertain which plants need to be re-potted and which require only to be top-dressed. Large specimens may remain for a considerable length of time without re-potting, and are capable of maintaining themselves in good condition. But the period during which they will be able to do this will vary according to the thoroughness in which the previous potting operation was carried out. If a collection contains a number of specimens, it is advisable to re-pot one or two of them each year, so that if the newly-potted plants do not immediately produce flowers, this loss will not be felt. Plants that are to be re-potted should have all the old material shaken from their roots, and after the mass has been pulled to pieces all the dead roots and old pseudo-bulbs should be cut away, leaving only three or four pseudo-bulbs behind each leading growth. Place the plants in clean receptacles of suitable sizes, and fill these with drainage materials to about two-thirds of their depth, over which place a layer of thin turf or rough moss. The rooting medium may be composed of turfy loam, peat, Osmunda fibre and Sphagnum-moss in equal parts, adding a liberal quantity of crushed crocks and silver sand. Let these ingredients be well mixed together and use them in a rough state. The specimens should be made up in a conical fashion, a commencement being made in the centre of the receptacle (the centre pseudo-bulbs thus being placed the highest), afterwards packing each piece securely with the potting mixture, and making use of copper wire pegs to hold them firmly in position. Let all the growths be placed in such a manner that they will point towards the centre. When the operation has been completed, place the plants in a shady position and spray them overhead frequently; also damp the staging in between the pots in order to prevent the pseudo-bulbs from shrivelling more than is unavoidable.

FRUITS UNDER GLASS.

By T. COOMBER, Gardener to LORD LLANGATTOCK, The Hendre, Monmouthshire.

Early vines.—As soon as the Grapes upon the early vines are ripe, the atmosphere of the house must be kept cooler than heretofore, and by free ventilation and a moderate amount of artificial heat the interior of the house should be kept drier than usual, for under these conditions the fruit will keep longer. In the earliest houses it is not usual to leave the fruit upon the vines for a sufficient length of time after it has ripened to necessitate the borders having to be watered before the fruit is gathered. But if for any reason it should be desirable to water the borders while ripe fruit is still hanging upon the vines, the watering should be carried out early in the morning of a bright day. In any case, directly the fruit has been gathered, the borders should be thoroughly moistened with weak liquid manure, and the vines should be forcibly syringed with clear water to cleanse them of red spider or any other pest. Endeavour to keep the leaves in a healthy and clean condition as long as possible, as this will enable the wood to become perfectly matured.

Mid-season vines.—Such vines as Black Hamburgh, Madresfield Court and similar varieties carrying crops of fruit for use at midsummer should be afforded weak farmyard manure water, or top-dressings of artificial manure, remembering always that the plants may be easily injured by over-doses of manure. Keep a close watch for red spider, and upon its first appearance sponge the leaves with soapy water. Attend to the stopping and tying of the shoots each week, and cut out from the bunches of fruit any seedless berries they may still contain. Maintain an atmospheric temperature at night of 60° to 65°. Ventilate the house early each morning, and close the ventilators sufficiently early in the afternoon to cause the temperature to rise to 85° or even 90°. Damp the surface of the borders early in the morning and again in the afternoon when the house has been closed to promote atmospheric moisture.

The late vines.—Our vines of such late varieties as Lady Downes Seedling, Appley Towers, Black Alicante, Alnwick Seedling, and Lady Hutt have not yet made such progress as is usual at this date. Examine the borders to see if they require water; thin out a few of the surplus inflorescences before the plants come into flower. At that period it will be necessary to promote the conditions that have already been recommended in this column for the earlier fruiting vines during their flowering stage. For the purposes of pollination, plants of Alnwick Seedling should be syringed, or the inflorescences should be touched by a camel's hair varnish brush in order to remove the glutinous exudations from the stigmas of the flowers, otherwise a bad set will result. If this be done, however, care should be taken to see that the blossoms will be dry at midday, when the pollen should be distributed. As soon as it can be ascertained which berries have set, the final thinning of the bunches may be carried out, and later, the thinning of the berries should be given attention. When thinning the berries, it should be borne in mind that the Grapes will not possess good keeping qualities if they are allowed to be overcrowded during their period of developing and ripening. It is desirable to remove any extra loose shoulders on such vines as Black Alicante, Alnwick Seedling, Lady Hutt and any others that are more or less prone to form unshapely bunches. In structures containing Gros Colmar or any other variety of Grape which is liable to have its leaves injured by the direct rays of the sun, it is necessary to afford sufficient shading to prevent this. For directions as to Muscat Grapes, the reader may turn to the Calendar printed in the issue for May 2.

THE FLOWER GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

Preparations for bedding-out.—It is but four weeks since we had 2 feet deep of snow and 14 degrees of frost. It is, therefore, not surprising that the spring-flowering plants have been much retarded. The summer bedding plants have necessarily been kept under glass longer than usual, and they are none the better for this, as it is often impossible to prevent them being crowded whilst still in the houses, and the temperatures are sometimes higher than is good for them. In these gardens the spring-flowering plants are just at their best, and their display is quite three weeks later than last year. The Wallflowers exhibit several new shades of colour, and their effect is very pleasing when such varieties as Eastern Queen, Old Gold, Vulcan, Spanish Queen, and others are grouped together.

Tuberous-rooted Begonias in mixed colours and planted in single beds are very effective for summer flowering, and in late years they have been substituted in many instances for Pelargoniums. If, however, they are planted in beds, forming part of a geometrical design, each bed should be planted with a variety of one colour. But if reds, pinks, whites, bronzes, and yellows are planted in sufficient quantities, the general tendency is for them to appear flat and uninteresting. Therefore, it is customary to introduce amongst them what are termed "dot" plants. For this purpose Gladioli are commendable, and may be used in named varieties of various colours. They should be planted at the same time as the Begonias. If the latter are planted in suitable soil, they make numerous roots, grow freely, and flower well. But it must be remembered that they require much moisture, and if some decayed leaves are intermixed with the soil, also a little soot and wood ashes, they will generally succeed better.

Vases.—In the numerous gardens where vases are used to ornament conspicuous positions in the flower garden, it is necessary that they should be so planted at the commencement that they will be able to afford a good effect immediately afterwards. Pelargoniums two years old are among the most suitable free-flowering plants for such cultivation, and autumn-rooted cuttings of Ivy-leaved Pelargoniums, together with Lobelia seedlings, may be used for the draping of the vases. It is desirable, when the vases are placed in different aspects, to provide for each vase presenting a separate colour. Excellent colours are afforded by such Pelargoniums as Henri Jacoby (deep crimson), Achievement (double pink), Paul Crampel (scarlet), Madame Crousse (pale pink), and Souvenir de Charles Turner (dark pink). Soil that is taken from beneath the potting bench is very suitable for filling the vases, and it should be made moderately firm about the roots of the plants, and be freely watered directly the work of planting has been completed.

Hollyhocks.—If seeds were sown early in February, as was advised in a previous Calendar, the plants should now occupy 5 or 6-inch pots. This method of raising Hollyhocks is desirable from several points of view. Such plants are less liable to the fungus disease than those raised from cuttings. They grow most freely, and there is always the possibility of obtaining varieties of extra good quality. I have found that isolated plants are less frequently the subjects of attacks from the disease, and for this reason it is better not to group Hollyhocks too closely together. If they are judiciously intermixed with Pompon and Cactus-flowering Dahlias, the effect is good. Both plants require deep, rich soil and frequent waterings during the summer months.

THE HARDY FRUIT GARDEN.

By F. JORDAN, Gardener to The DOWAGER LADY NUNBURNHOLME, Warter Priory, Yorkshire.

Fruit prospects.—In this district it is as yet impossible to determine what the effects of the recent unfavourable weather will be. However, blossom is very plentiful on most trees, and if a quarter of their number should set well there will be good crops of fruit. Plum trees appear to have fewer blossoms than most other crops, and Strawberry plants vary much in appearance, Givon's Late Prolific having apparently suffered most from the inclement weather.

Disbudding.—This work will now be in full progress upon Peach and Apricot trees, and in more southern districts than this the work will soon be completed. Do not allow trees that have failed to set fruits to be neglected in this matter, but disbud them equally with the others. The details of disbudding Apricots and Peaches were discussed in the Calendars printed in the issues for April 18 and 25. I need, therefore, only say that the operation should be carried out during mild weather as far as possible, and that the weakest-growing trees should be left until last, by which time they will have gained a little strength. The operation of disbudding the shoots and thinning-out the fruits of all trees should be entrusted only to experienced men. A well-balanced and fertile tree may often be secured by the timely removal of badly-placed shoots and the pinching-in of others. If the work is properly done, this will render it unnecessary to employ the knife severely in the winter season.

Vines out-of-doors.—Last year the out-of-door vines were generally failures; but this should not cause us to neglect the plants in the present season. By giving early attention to the matters of disbudding, and the stopping and tying-in of the shoots, much may be done to secure a better return this year. But apart from their fruit, out-of-door vines are very ornamental, and from this point of view alone they are worth cultivation. Disbudding should be commenced as soon as it can be seen which shoots will produce the best bunches of fruits. Not more than one shoot and one bunch should be allowed to each spur, unless there is much wall space it is desirable to cover. The young shoots should, in all cases, be stopped at the first "joint" beyond the bunch, and the shoots should be tied close to the face of the wall, in order that they may benefit from the warmth which is absorbed by the wall. Every lateral should be pinched at the first leaf. Watering may need to be done during dry weather, especially if the vines are growing against hot buildings, and frequent applications of liquid manure should be made.

PLANTS UNDER GLASS.

By THOMAS LUNT, Gardener to A. STIRLING, Esq., Keir, Perthshire, N.B.

The Stove.—Plants that are now growing quickly and are known to be liable to the mealy bug should be frequently examined in order to destroy this pest before it becomes prevalent in the collection. The best method of cleansing infested plants is by using an insecticide called "The Empire." If this is applied by means of an "Empire" sprayer one man will be able to cleanse many plants in a very short time.

Shading and ventilation.—These matters should receive extra attention at the present time, when the weather is changeable and sunshine most fitful. Care should be taken never to allow the blinds to remain down after the sky has become clouded. Stove foliage plants will now require to be syringed twice each day. After syringing has been done in the morning a small amount of ventilation should be employed, and an equal amount should be left on after the plants have been syringed in the afternoon until the foliage has again become dry. Do not hesitate to freely ventilate the stove when the outside temperature is not lower than 60°, for if draughts be prevented the additional air will benefit the plants. Frequently damp the surfaces in the house during the middle of the day in order to promote atmospheric moisture.

Allamanda, Dipladenia, Stephanotis and Gloriosa.—These plants are now growing very quickly, therefore the shoots require to be regulated in order that each may be exposed well to the light, and for the same purpose any surplus shoots should be removed.

Bougainvillea.—These plants flower best when the shoots are trained under the roof of a house and allowed to depend from the roof. As soon as the plants have passed out of flower, the flowering shoots should all be cut off and a second display of bloom may then be expected in the autumn.

Salvia splendens.—When sufficient cuttings have been taken for purposes of propagation, the old plants may be planted out into an unheated frame, where the lights can be removed later in the season. If treated in this way the plants are not likely to suffer much from red spider, and in September, if the roots be cut round with a spade a few days before lifting the plants, they may be potted up and will form handsome specimens for flowering in the greenhouse.

Bouvardia.—If treated in the manner recommended for Salvia splendens, Bouvardias will succeed well; the climate of Scotland is too cold to allow us to plant the Bouvardias entirely in the open. A suitable compost for these plants is one consisting of good loam, leaf-soil and sand, and it should be pressed firmly about the roots at the time of planting. Keep the frame closed for a few days after the planting has been done, and syringe the plants each afternoon if the weather is favourable.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree, Hertfordshire.

Over-crowding of crops.—One of the greatest and most frequent mistakes of kitchen gardening is that of allowing the crops to become overcrowded through insufficient thinning. This applies to nearly every crop in all kinds of soils. Ten or more plants are frequently allowed to occupy space that is merely sufficient for one plant. Peas and Beans are, perhaps, amongst the first to suffer when treated in this manner. Not only do they yield a deficient crop, but the period of cropping is also of much shorter duration. It is, nevertheless, a good plan to sow the seeds just about as thick again as it is intended to allow the plants to develop; but after this has been done the thinning must not be neglected. It should be carried out in two operations, and the earlier it is done the better are the results.

Fertilisers.—During the next month or six weeks everything should be done that is possible to encourage vegetables of all kinds to make uninterrupted growth. In most cases, but especially upon land that is not sufficiently rich, applications of some suitable fertiliser are needful. There are many artificial compounds now on the market, which, if applied according to the directions issued with the manures, are capable of benefiting the crops. For many years past I have used Clay's Fertiliser, with excellent results, and for Potato crops Messrs. Wood & Sons have a preparation which is equally valuable. Fresh soot is a good fertiliser, and it is also valuable as a deterrent of birds and other pests. Young seedling Carrots and Celery are liable to become infested with green aphis at this season of the year, and in such cases they should be syringed with the X.L.-All liquid directly the pest is observed. One application, if made with care, generally proves sufficient to destroy the pest. Slugs are very numerous this year, and only by the greatest perseverance can many of the crops be saved from their ravages. As a preventive, however, the soil should be broken as finely as possible, and made quite firm about the young plants. After this has been done, the surface should be entirely covered with finely-sifted cinder ashes. Having tried many remedies, I have found nothing so effective as these ashes, which slugs have a great objection to crossing.

Potatos.—Immediately the young growths of the earlier Potatos appear above the soil, let the soil between the rows be hoed with the flat hoe, and when the growths are 3 inches above the soil, let earthing-up be carried out. Keep a sharp look-out for frost, and when this is likely to occur afford the plants some protection.

Runner Beans.—Seedlings which have been raised in pots or boxes under glass should now be thoroughly hardened off and got into readiness for planting in the permanent rows before the end of the present month. The plants should be put into well-prepared trenches, into which plenty of good manure has been worked. Plant two rows in each trench, and allow at least a distance of 12 inches between the plants. The trenches should be separated from each other by distances of 10 or 12 feet. Take every precaution to protect the young plants against snails and slugs, and apply stakes to the rows at the time of planting. The stakes should be as long as it is possible to get them. Each should be thrust well into the ground, and at intervals they should be supported by cross stakes tied with strong tarred cord. Another sowing may now be made in the open garden

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, MAY 25—
Ann. meet and dinner of the Kew Guild at the Holborn Restaurant. Anniversary meet. of the Linnean Soc.

TUESDAY, MAY 26—
Roy. Hort. Soc. Sh. in the Temple Gardens, Thames Embankment (3 days).

WEDNESDAY, MAY 27—
Ann. meet. Brit. Gard Assoc. in Essex Hall, Strand, 7 p.m. Bath and West and Southern Counties Soc. Sh. at Dorchester (5 days).

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—55·9°.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, May 20* (6 P.M.): Max. 73°; Min. 54°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London. *Thursday, May 21* (10 A.M.): Bar. 29·8; Temp. 64°; *Weather*—Bright sunshine.
PROVINCES.—*Wednesday, May 20* (6 P.M.): Max. 58° Colchester; Min 51° Ireland N.W.

SALES FOR THE ENSUING WEEK.

TUESDAY—
100 magnificent Orchids, by order of Messrs. Sander & Sons, by Protheroe & Morris, at 67 & 68, Cheapside, E.C., at 2.30.

THURSDAY—
Selected Plants from the Chillingham collection of Orchids, by Protheroe & Morris, at 67 & 68, Cheapside, E.C., at 1.

FRIDAY—
Special Sale of Orchids, by Protheroe & Morris, at 67 & 68, Cheapside, E.C., at 12.45.

Gardeners' Orphans.

In this country the State makes no provision for maintaining its orphans other than that afforded by workhouses and similar institutions, that, however, do not in this connection commend themselves to British sentiment. So long as these conditions exist there will always present themselves in every industry and profession sufficient grounds for the exercise of private charity.

We know that in various industries, societies and communities, praiseworthy efforts are made to maintain the fatherless children of those who were formerly numbered amongst the productive workers in the industries, or who were members of the societies, but have fallen prematurely from the ranks through death. It would be an easy matter for us to urge that the conditions of employment in practical gardening are such as to make it doubly imperative upon horticulturists to do their very best in the interests of gardeners' orphans. At the recent Festival Dinner of the Royal Gardeners' Orphan Fund, which was reported in our last issue, one of the speakers referred to the emoluments and the status accorded to gardeners as being incommensurate with the responsibilities entrusted to them, and insufficient to enable them to make proper provision for support in old age. We have urged the same thing over and over again, and we hope that in the future employers generally will learn to appreciate more correctly the value of the services rendered by their gardeners, and will show their increased appreciation in a substantial and satisfactory manner.

But it is not necessary to rest the case of the orphans even upon the generally low scale of the salaries paid to gardeners, for the need of charity would often arise even if the wages were satisfactory. Visitations of illness and death are casualties that affect the comparatively young in life as well as those of riper years, and many a worker is permanently removed from the scene of his toil before he could possibly accomplish much in the nature of providing for those who are naturally dependent upon him. In such cases as these it is the bounden duty of those who survive to afford the provision their fallen comrades were unable to make.

It is, therefore, a matter for general satisfaction that the recent Festival Dinner of the Royal Gardeners' Orphan Fund was attended with the success we were able to record in our last issue. The Fund was instituted in 1887 to commemorate the Jubilee of Her Majesty Queen Victoria, and coming generations are likely to say, as we say at this time, that gardeners could not possibly have chosen a more commendable method of commemoration. Although it is but 21 years since this happened, many of those who were among the first and most ardent supporters are no longer with us. In such a short period their labours are well and appreciatively remembered, and whilst their loss is mourned, there is the satisfaction that new workers have been forthcoming, and that changes by death or otherwise have not been allowed permanently to impede the general progression of the Fund. Its original objects were to make allowances not exceeding five shillings per week to the "Orphans of Gardeners, Foremen in Public, Private and Market Gardens, and the Managers or Departmental Foremen in Nursery and Seed Establishments" until they reach the age of 14 years, and subsequently by means of special grants to assist them in providing clothing or tools or apprenticeship fees when commencing to earn their own livelihood.

In faithfully carrying out these objects the fund has expended a sum of money amounting to £18,000, and during the same period has invested funds that yield more than sufficient interest to defray the whole of the cost of management. At the present time there are 116 orphan children, for whose maintenance until they are 14 years of age the Executive Committee has assumed responsibility. To accept Mr. Poupart's simile, how the "sport" of 1887 has flourished!

The most optimistic of those who helped to found the fund could hardly have anticipated that its "Coming-of-Age" would be celebrated in such auspicious circumstances.

At the recent festival the chair was appropriately filled by the President of the fund, the Duke of Bedford, K.G., who showed his active interest by fulfilling the duties of this position and subscribing £250. A feature of the meeting was the announcement by the treasurer, Mr. Edward Sherwood, that his father, brother, and himself would subscribe a sum to provide permanently sufficient interest to maintain one orphan. Another satisfactory circumstance was the statement by the secretary, Mr. Wynne, that the shilling contribution suggested in February last by Mr. H. J. Clayton, one of the founders, had resulted in the collection of £230, a sum which has since received considerable additions.

The committee, of which Mr. Henry B. May is chairman, and stewards had worked well, and the total subscription, exclusive of the "Sherwood" or "Maybud Campbell" gift, was £1,385, being a greater amount than has ever been raised at an annual festival.

There are two matters mentioned in the speeches to the toast of "Gardeners and Gardening" that deserve emphasis. One is the point urged by the Mayor of Westminster, Mr. John W. Dennis, J.P., that it is more than ever necessary for gardeners to avail themselves of the latest knowledge gained in the science and art of gardening, and the other is the plea made by Dr. Farmer, F.R.S., that horticulture should be given political recognition by the State and official recognition at the universities.

Reverting to the fund, it only remains for us to appeal to gardeners and proprietors of gardens to do their utmost to increase the number of annual subscribers that progress may still be maintained during the new epoch upon which the charity has now embarked.

OUR SUPPLEMENTARY ILLUSTRATION depicts a portion of the Rhododendron Dell at Kew as it appears in May and June. Surrounded by tall trees, the visitor, as he listens to the singing of the birds and obtains a chance view of a squirrel on the path in the distance, might imagine himself to be in the woods of an estate far removed from the electric tramcars and motor omnibuses, rather than a spot only some six miles from the centre of London. Situated on the western side of the gardens, and extending parallel with the river Thames, the long, winding valley or depression is nearly a quarter of a mile in length. Originally known as the "Hollow Walk," it is said to have been excavated by the Staffordshire Militia when quartered at Kew, in the reign of George the Third. Sheltered on either side by tall trees and evergreen shrubs, especially Hollies, being a low-lying situation, and so close to the river (100 to 150 yards), the position is fairly moist. The supplementary illustration shows the dell looking from N.E. to S.W. Sir WILLIAM HOOKER commenced the planting of Rhododendrons on this spot, and now the whole of the banks, for some distance in places on either side of the walk, are clothed with masses of the finest of the hardy Rhododendrons, a goodly number of which have attained to considerable dimensions. The collection is added to every year. It is also necessary from time to time to move large plants, to give others more space to develop. This means that the area occupied by the Rhododendrons is increasing, and it is doing this both in length and breadth wherever possible. The shelter afforded by the banks and trees and shrubs previously mentioned make it possible to grow some of the hardiest of the Himalayan and Chinese species, together with their hybrids. Near the centre of the dell a few Camellias have also been planted. The illustration at fig. 149 shows a large specimen of R. Cunninghamii on the right, the smaller plants in the centre of the picture being R. Griffithianum (Aucklandii) hybrids, notable

for their large flowers, and considered by many growers to be the finest of all Rhododendrons. Unfortunately, it is only possible in this country to grow them outside in sheltered positions, except in the favourable climate of the south-west and one or two similar localities. A pretty Himalayan species flowering in the dell at present is R. campylocarpum, the flowers are bell-shaped, pale yellow, and about 2 inches across. A few of the best Rhododendrons also at present in flower are Ascot Brilliant (rich red), John Waterer (deep rosy-red), Macranthus (white-flushed purple), Manglesii (large white flowers, tinted pink, especially in bud), Prince Louise (white, almost prostrate in habit), Auguste van Geert (rosy-purple), Hamilcar (purple), and Broughtonii (deep rosy-red, a very large specimen).

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—We wish to remind our readers that the 69th anniversary festival dinner in aid of the funds of this institution will take place on Wednesday, June 24 next, at the Hotel Metropole, under the presidency of the Rt Hon. the Lord ALDENHAM. Subscriptions or donations to be placed on the chairman's list for announcement at the dinner are earnestly solicited, and may be sent direct to Lord ALDENHAM, or to Mr. GEORGE J. INGRAM, secretary, at the offices, 175, Victoria Street, Westminster, S.W.

FIG. 149.—RHODODENDRONS AT KEW, SHOWING A FINE SPECIMEN OF R. CUNNINGHAMII IN FLOWER ON THE RIGHT.

THE TEMPLE FLOWER SHOW will be opened on Tuesday next, and will remain open until the 28th inst. Judging will commence at 10 a.m. on the opening day, and half an hour later the members of the Floral and Orchid Committees will assemble, but there will be no meeting of the Fruit and Vegetable Committee. At 12 noon the exhibition will be open to the Fellows and the public. Fellows are reminded that there will be a private view from 7 a.m. to noon on Wednesday, May 27, when admission will be by Fellows tickets only. Gardeners may obtain 2s. 6d. tickets for 1s., which will admit them to the show on Wednesday between the hours of 12 noon and 7 p.m. These special tickets must be obtained on or before May 23 from the secretary of the society. The Temple Gardens are easy of access by the District, and most of the other underground railways of London. The London County Council's tram system passes by the main entrance to the exhibition, and this year the new connection with the North London tramways will be available for visitors. In addition, there are numerous services of horse and motor 'buses which pass by the Law Courts in Fleet Street, which are close to the show ground.

A GARDENER'S GOLDEN WEDDING.—Mr and Mrs. BLACK, of Smeaton Gardens, East Lothian, recently celebrated their golden wedding, writes a correspondent, when they were the recipients of many presents, those from Sir ARCHIBALD and Lady SMEATON HEPBURN being a gold watch for Mr. BLACK and a diamond brooch for Mrs. BLACK. For a number of years Mr. BLACK has had charge of everything connected with the estate, with the exception of the farm. A large rock-garden has been constructed in recent years, but Orchids are, perhaps, still the favourite plants of this veteran gardener, who has several sons following in his steps, of whom some are settled in situations in America, but the eldest (Mr. ALEXANDER BLACK) is head-gardener to the Duke of LEINSTER, at Carlton. Mr. BLACK, it may be added, completes his fiftieth year as gardener at Smeaton next November, and is still hale and hearty and as enthusiastic a gardener as ever he was.

MR. B. H. THWAITE, whose death has been recently announced, devoted considerable attention to the subject of applying electricity to the roots of cultivated plants. His system was described in our issue for September 8, 1906, p. 180. Before the commencement of his illness Mr. THWAITE was engaged in conducting experiments at the Royal Botanic Society's Gardens, Regent's Park

RECENTLY INTRODUCED PLANTS. — M. MAURICE L. DE VILMORIN exhibited at the Ghent Show a large number of plants in pots, being recently introduced species. Many of these were trees and shrubs that have already been described in these pages and elsewhere, but owing to the early date of the season, the plants had made very little growth, and in consequence

were not attractive to the general public. M. VILMORIN has now published a list of the species and varieties, and the pamphlet is illustrated. The exhibit was awarded a Gold Medal.

THE LATE MR. BERNARD COWAN, whose death occurred on May 5 at South Shields, was on occasional contributor to these pages. He had been superintendent of the Cemeteries under the South Shields Burial Board and latterly the Corporation for a period of thirty years, and previous to his appointment was head gardener to Sir WILLIAM HUTT, of Gibside, and Sir. H. CLAVERING, of Axwell Park. He was vice-president of the English Arboricultural Society and joint secretary of the South Shields Chrysanthemum Society. Many gardeners have visited the South Shields burial grounds, especially the Horton Cemetery, which Mr. COWAN had laid out in a most admirable style and maintained in such a manner that it was one of the most beautiful places in the borough.

ABERDEEN AND NORTH OF SCOTLAND COLLEGE OF AGRICULTURE.—Much justification is being expressed in educational circles in the North, writes a correspondent, at the scheme for the extension of the work of this college at present under the consideration of the Government and the Scottish Education Department. Should it be adopted—as seems likely to be the case—a very considerable impetus will be given to the development of the work of the college. The aim of the Scottish Department is to weave agricultural education into the general educational system of the country. This will involve, in the first place, an addition to the curriculum of rural schools, and here the college will have to give all the assistance possible to effect this object. The college will be expected to advise and consult with school boards as to laying out school gardens, not for the purpose of teaching the children to be horticulturists, but rather for inspiring them with a love for nature study, especially as it is exhibited in the plant life around them. To be complete and effective nothing could be more natural than that such instruction should originate in our rural schools, where it will find its readiest and most receptive pupils in those who are born and bred among country pursuits, and who will, in the large percentage of cases, be destined to follow such pursuits. But the function of the college under the scheme will not merely be to furnish this instruction in its higher forms, but it will also provide courses of study for students and particularly to train teachers. Other developments are also in contemplation, all having a bearing on rural life, while the provision of an experimental farm is not being overlooked. Altogether the extension scheme appears to have all the elements of practicality about it, and should it come to be applied—as there is every prospect of its being—there can be no manner of doubt as to the beneficial results that are bound to follow. In agriculture and horticulture, as in everything else, improved education must lead to an improvement in methods and to the elevation and increased importance of these industries. That these are the expectations entertained may be inferred from the hearty manner in which the governors of the college approved the scheme at a meeting they held the other day.

SURVEYORS' INSTITUTION.—The annual general meeting of the institution, to receive the report of the council and the announcement of the result of the election of officers for the ensuing year, will be held in the Lecture Hall on Monday, May 25, 1908, at 3 o'clock. The prizes awarded to successful candidates, in connection with the recent preliminary and professional examinations, will be presented by the president at the annual general meeting.

FLOWERS IN SEASON.—From the Knapp Hill Nursery, Woking, Mr. ANTHONY WATERER sends us examples of several interesting shrubs in flower, including a very fine form of the old Cydonia japonica, named Knapphill Scarlet; a double-flowered form of the Bird Cherry, Cerasus padus, and heavily-flowered sprays of the single form of this plant, the long racemes of flowers being borne in great numbers on quite small twigs. Another interesting plant sent is Pyrus Malus, variety Niedzwetzkyana, with flowers of a vinous-red colour. The fruits of this plant are of interest in the autumn, when they are of the same colour as the bark of the shoots. Mr. WATERER informs us that the sprays of Cerasus padus "Knapp Hill variety" were taken from a large tree about 30 feet high, and having a spread of branches of the same measurement. The tree must present a grand spectacle at this season when covered with its long, drooping inflorescences of white blossoms. A flower of the beautiful Oncidium tetracopis has been sent us by Messrs. STANLEY & Co., Southgate, London, who inform us that it was taken from a plant bearing more than 120 flowers.

BATH AND WEST AND SOUTHERN COUNTIES SOCIETY'S SHOW will be held at Dorchester from May 27 to June 1. Besides agriculture the schedule makes provision for horticulture and forestry.

DECORATIONS AT CHESTER.—On the occasion of the recent visit of His Majesty the KING to this historic city, one of the principal of the street decorations was contributed by Messrs. DICKSONS, Ltd., the well-known seedsmen and nurserymen. Their offices have one of the largest frontages in Chester, and this was decorated with flowers and foliage plants. The balconies were occupied with Daffodils and scarlet Pelargoniums in broad lines. Hanging baskets were filled with the same flowers, while Palms, Ferns, trailers of Smilax, and Ivy completed a most effective display. The windows were also filled with floral subjects. The decorations were described by the local Press as the most striking feature of the street decorations.

CARNATIONS AT GHENT.—Messrs. Low & Co., Bush Hill Park Nurseries, inform us that, since the general prizes were awarded at the Ghent Show, they have received a medal for their exhibit of Carnations already referred to in these columns.

PROPOSED NEW PARK FOR ABERDEEN.—A number of the leading citizens of the West End of Aberdeen have petitioned the City Council on the advisability of acquiring the lands of Bleachfield, situated on the outskirts of the West End of Aberdeen, for the purpose of establishing a public park. This is the only part of the city which does not possess a public park. There are already in the city some seven parks or open spaces, but all these are situated a good distance from the West End. The lands in question, at Rubislaw, Bleachfield, consist of about 25 acres, and are delightfully situated. Large lakes are already there, and a goodly volume of water runs through them. The lands belong to the Aberdeen Land Association, and the terms offered the Council by this company are regarded as favourable. The stipulation is that not less than 15 acres must be acquired, the terms being £400 per acre. It is not at all likely, however, should the Town Council adopt the project, that they will restrict the purchase to 15 acres, but will no doubt acquire the whole area of 25 acres which is available. That the time is opportune for the purchase and the price favourable may be understood when it is stated that only four or five years ago the price for the same ground was £850 per acre. It is not so very long ago that the city had to pay thousands of pounds for a mere strip of the land, the whole of which could have been acquired some 20 years earlier for a nominal sum. The general feeling is that the Town Council should not allow so favourable an opportunity to pass of adding to the number of places in the city desirable for recreation and amusement.

SUN-DRIED COLONIAL FRUITS.—The recent success of the sun-dried Australian and Cape fruits in the London markets, says the *Times*, has attracted considerable attention from importers and distributors in this country. It is agreed that the sun-dried and crystallised Figs from Australia and the Cape respectively were the finest fruits of their class which have ever been put upon the British markets. The retailers were able to dispose of them at the rate of 3s. a dozen, this being a record price for such fruits. The Colonial producers have proved unmistakably their ability to control the trade in these fruits in England, provided they can ship enough to meet the wants of the trade buyers. One Eastcheap firm considers that these sun-dried fruits, packed attractively in one-layer small boxes, could be disposed of in large quantities at high prices with ease. Sun-dried Figs, Apricots, Peaches, Plums, &c., equal in grade to the specimen Figs recently shipped to England, would be sure to find a market.

WATER-COLOURS DEPICTING JAPANESE SCENERY.—An exhibition of garden and other scenery in Japan, executed on the spot by Miss ELLA DU CANE, is on view at the Fine Art Society's Galleries, 148, New Bond Street, W. There are in all some ninety paintings, the scenes for which have been well chosen. Flowering subjects predominate, and these are chiefly those of the spring season. The summer is indicated in finely-executed drawings of the Lotus family and of the Iris, whilst the later summer is represented by the season of the Blue Hydrangea. There are effective pictures representing the coast scenery of Japan, others deal with such subjects as small islets with Pine trees thereon. The stepping-stones, so characteristic of Japanese gardens, are shown in many and varied forms of arrangement. The colours of some of the flowering plants are intense, but they are not overdone, for the clearer skies of Japan conduce to deeper tints of colour in flowers than we see in England.

ANNUAL MEETING OF THE KEW GUILD.—We are requested to again remind old Kew men that the annual meeting and dinner of the Kew Guild will take place at the Holborn Restaurant on Monday evening next. Mr. W. W. PETTIGREW, superintendent of the Cardiff parks and open spaces, will preside at the dinner.

*** TREES AND SHRUBS.**—The fact that this work should have reached its third edition plainly shows it supplies a need, and the moderate price at which it is published places it within the reach of all who may desire to select trees or shrubs for planting. As a general guide, and as showing the large variety of plants available, it is most useful, even although in some cases it may be found to suggest a choice with a cheery optimism that experience will, perhaps, sometimes fail to justify. It is a book which should be in the hands of all those charged with planting public parks or large gardens. Advantage has been taken of the issue of this edition to bring the work up-to-date.

* *Hardy Ornamental Flowering Trees and Shrubs*, by A. D. Webster. Third edition. London: Smith Elder & Co. 1908. Price 3s. 6d.

EXTERMINATION OF RATS.—These rodents are as much a pest to the gamekeeper, and any means of exterminating them is welcomed. The substance Ratin, which has been referred to in these columns on former occasions, is the subject of a little pamphlet describing the extermination of rats on the island of Little Cumbrae, situated at the mouth of the Forth of Clyde. The island is about 900 acres in extent, and was formerly a famous sporting estate, rabbit and woodcock shooting being abundant. But the place has long suffered from the depredations of rats, and this evil was augmented by a number of these creatures which reached the shore from a wrecked ship. It therefore became necessary to institute a war against them, and a quantity of Ratin was laid about their haunts, in all some 2,200 packets of the specific being used. The poison was applied in January, 1908, and in March a thorough inspection of the island was made, with the result that no trace of rats could be found.

A COLOUR CHART.—The question of a cheap work for identifying the colours of flowers has been discussed by members of the National Sweet Pea Society, and an open letter on the subject has been addressed to the Hon. Secretary of that society by Mr. STANLEY BROOKE, of York. The secretary, Mr. CHAS. H. CURTIS, in his reply, states that it is unlikely the National Sweet Pea Society will be able to undertake the cost of preparing such a work, but if it is recognised that it would be equally valuable to kindred societies such as the Rose, Dahlia, Carnation and Chrysanthemum Societies, these societies might be induced to issue a chart conjointly, and, failing them, the Royal Horticultural Society might be asked to undertake the task. The cost of the work should be small enough to enable it to be purchased by the members, for it is found that the *Repertoire des Couleurs*, although an excellent colour chart, is too expensive to be of general use.

PRIZES FOR HYACINTHS.—The Dutch Bulb Grower's Society at Haarlem is offering, under the auspices of the Royal Horticultural Society, prizes for forced Hyacinths, to be competed for at the Royal Horticultural Society's exhibition to be held on March 9, 1909. There are four classes, three being for amateurs, and gentlemen's gardeners, and the other for nurserymen only, who are offered as a first prize the Gold Medal (valued at £50) of the Dutch Bulb Grower's Society at Haarlem for the finest collection of Hyacinths, either in pots, pans, or in glasses.

Publications Received.—*Pansies and Violets*, by D. B. Crane, F.R.H.S. Illustrated. (London: The "Amateur Gardening" Office, 148 & 149, Aldersgate Street, E.C.) Price 1s. net.—*Hardy Ornamental Flowering Trees and Shrubs*, by A. D. Webster. Third edition. (London: Smith Elder & Co.) Price 3s. 6d. net.—*London Parks and Gardens*, by the Hon. Mrs. Evelyn Cecil. With illustrations by Lady Victoria Manners. (London: Archibald Constable & Co., Ltd.) Price 21s.—*The Nature Book*: A Popular Description by Pen and Camera of the Delights and Beauties of the Open Air. In parts; 7d. net. (London: Cassell & Co., Ltd.)

PYRUS JOHN SEDEN (PEAR × QUINCE).

THIS interesting fruit was raised by Messrs. J. Veitch & Sons at their Langley Nursery in 1895 from Pear Bergamotte Esperen and the Portugal Quince, a variety of Pyrus Cydonia, the latter being the pollen parent. Three plants were raised from seeds taken from the same fruit, and of these two have fruited, while the third has produced a dwarf and somewhat stunted tree.

The plant of which the fruit is illustrated at fig. 150 is similar to the Quince in its general habit and foliage, and the time and method of flowering coincides with that of the Quince. At the present time the fruits are quite firm, and will probably keep in a good condition for a considerable period. When first gathered the colour of the fruit was a grass green, but it became slightly darker. The flavour is distinctly that of the Quince.

The other tree resembles the Pear in every respect, and the mode of flowering is in trusses, the same as in the mother parent. Its fruits are pear-shaped and they have a rich Bergamotte flavour. They were ripe early in November and developed a reddish-brown colour. *T. W. B.*

FLORAL BEDDING ARRANGEMENTS.

THE season is at hand when the beds in the flower gardens will need furnishing with their summer and early autumn occupants. Owing to the lateness of the season, many of the spring-flowering plants, such as Myosotis dissitiflora, Wallflowers, Aubrietias, and Violas, which now occupy the beds, can scarcely be said to be in full flower, and Silene pendula compacta, Saxifraga umbrosa, and such-like plants, will not be in flower for another week or two. The majority of the plants employed in spring bedding are not, as a rule, at their best before the third week in May, or the end of that month, when it is time to plant the summer occupants of the beds, such as the different sections of Pelargoniums, Calceolarias, Ageratums, Lobelias and Fuchsias. The gardener is loath to break up the pleasing floral picture furnished by the blue Forget-me-nots, pink Silene, Wallflowers, &c., but he is also mindful of the floral effect that has to be produced by summer-flowering plants in the same beds by the middle or end of July, hence his anxiety to plant the ordinary summer bedding as soon after the end of the third week in May as the weather and other circumstances will permit. Three weeks or a month later will be soon enough to plant out tuberous Begonias, Alternantheras, Mesembryanthemum cordifolium variegatum, Heliotropes, and similar tender plants.

In the meantime the work preparatory to bedding out must be proceeded with in a judicious and active manner. The bedding plants require properly hardening, taking them from the Vineries and Peach-houses to cold pits and frames, where, after a few days, the sashes can be drawn off during the daytime, afterwards shifting the plants—for lack of better accommodation into improvised frames in a sunny aspect, covering them at night with mats. In gardens where "carpet" bedding is practised, the beds should be manured, dug, trodden, and made level with the rake preparatory to setting out the designs, which should be simple and proportionate in their several parts, and be neatly executed. A few beds in every flower garden should be devoted to a modified form of the "carpet pattern" style of bedding. Plants of erect and graceful growth, different shades of colour, and varying in height from 9 to 21 inches, should be judiciously interspersed to counteract the flatness produced by the dwarf-growing foliage plants forming the ground plan. A few beds of this description form a pleasing contrast to the effect produced by the masses of scarlet, pink, white, yellow, blue, mauve, and other coloured flowers.

The beds in which Pelargoniums are to be planted should be prepared for their reception by digging in a light dressing of decayed manure, commencing with the beds containing the earliest spring-flowering plants, by removing those intended for use another year to the reserve garden, and planting the surplus plants here and there on either side of favourite walks and drives in the home woods, &c. Oblong and large circular beds planted with the silver-foliaged and scarlet-flowered Pelargoniums Bijou,

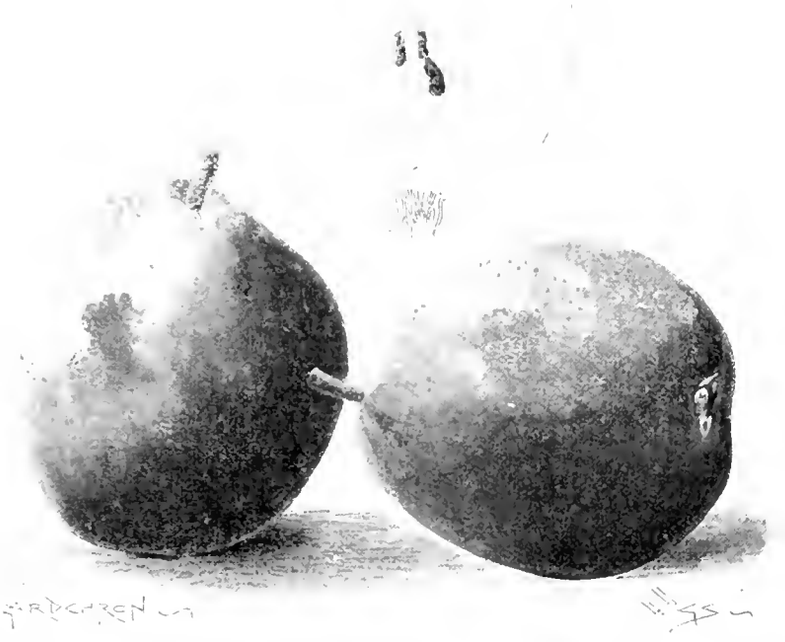

FIG. 150.—PYRUS "JOHN SEDEN," BEING A CROSS BETWEEN THE PEAR AND QUINCE.
(From specimens exhibited by Messrs. Jas. Veitch & Sons.)

with tufts of Blue Perfection Viola planted between, has a pleasing effect, as also has the Golden Queen Viola planted among the bronze and tricolor-leaved Pelargoniums. Some gardening acquaintances of mine used to advocate affording the plants plenty of room in the beds to develop, which meant that the beds are scantily furnished until within a few weeks of their being ruined by autumn frosts. The soil in which the plants are growing should be quite moist when they are being transplanted, and the soil should be made firm about the roots. During the interval from the time of setting the plants in the beds and the date at which the beds are wanted at their best, keep the flowers picked off, and any of the plants showing a disposition to outgrow their neighbours should have the points of the shoots pinched out, so as to promote a balance of growth, and thereby give the beds a unitorm appearance.

Masses of colour may be obtained by planting beds with the following varieties of the Pelargonium: Henri Jacoby (crimson), Raspail(semi-double, crimson), Denmark (producing large trusses of salmon-pink), Charles Turner, ivyleaf (cerise), Niphetos (double white), Indian Yellow (yellow), Crystal Palace Gem (golden leaved), Calceolaria amplexicaulis (lemon colour), Ageratum Tom Thumb (mauve), Lobelia pumila magnifica (deep blue). Beds planted with sub-tropical subjects, such as Ricinus, Abutilon, Variegated Maize, Nicotiana affinis, Solanum, Agave, Yucca, Acacia lophantha, Grevillea robusta, Dactylis glomerata longissima, Perilla nankinensis, with a groundwork of Coleus Verschaffeltii, would contrast effectively with the beds filled as indicated above, and to which effect a few beds planted with Heliotrope and Mignonette will add fragrance as well as variety. In conclusion, if beds in which tuberous-rooting Begonias are planted be covered with the silvery or golden Sedum, it will ultimately prevent the foliage and flowers of the Begonias from being splashed by heavy rains. At the time plants are being put out, water should be given at the roots, and repeated at frequent intervals until they are established. *H. W. W.*

FORCING RHUBARB BY ETHERISATION.

According to the *Canadian Florist*, experiments in forcing Rhubarb by ether were carried out last winter at the Cornell University Research Station, and comparisons made with the produce obtained under ordinary conditions. The experiments were started on December 26 with three clumps of etherised and the same number of unetherised clumps of Rhubarb. Care was taken to have the clumps as nearly of the same weight as possible. The effect of the ether was very pronounced, the leaves of the etherised clumps being ready to cut fully five days before those from the unetherised clumps. Not only were the shoots earlier in the case of the treated plants, but there were more of them. There were in all four cuttings; the first was made on January 29, and the last on February 10. The total gain in weight as compared with the unetherised clumps was 2 lbs. 4 ozs. in favour of the etherised batch, which was equal to 33 per cent. gain.

The cost of etherisation is small. The price for a perfectly airtight box need not be great, and any handy man can make one, and if there are cracks in it, these can be stopped with felt-paper. Commercial sulphuric acid, such as is required for etherisation, costs 75 cents per pound, which quantity is sufficient to etherise 30 good-sized roots. Thus the cost of the process is more than balanced by the five days' gain in time, and the extra quantity of Rhubarb produced by the process. *E. M.*

LAW NOTE.

CLAIM FOR BULBS.

Before Judge Allen, at the Nottingham County Court, on Thursday, May 14, Messrs. W. R. Alkemade & Co., of Holland, claimed £49 3s. 6d., the balance of an account of £69 3s. 6d. for bulbs, &c., sold and delivered to J. S. Fisher, nurseryman, of Wells Road, Nottingham. The defendant, who has a stall in the market place, made a counter-claim for £54 19s., on the ground that some of the bulbs supplied were diseased, some were not true to name, and he had suffered loss of trade in consequence.

Defendant said that in 1905 he complained about the quality of the goods he received, but when he gave the order in 1906 he was assured that the bulbs would be more satisfactory. After the bulbs had been received a week they went soft and developed a disease. He sold about 1,000 of the bulbs, and he had many returned from his customers, resulting in loss of trade. The plaintiffs alleged that no complaint was made to them until seven months after the bulbs had been delivered. If a complaint had been made immediately they would have been willing to consider it.

His Honour held that the Hyacinths were not of the best quality, and that the Narcissi were unsaleable, but that the claim for damage for loss of trade had not been substantiated. Judgment was given for the plaintiffs on the claim for the full amount, and for the defendent on the counter-claim for £18 16s.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

Apple Charles Ross.—It is evident that *A Working Grower's* reference to Charles Ross (p. 314) is in no sense praise, when he refers to it as a spoilt Peasgood's Nonsuch. Having regard to what seems a very local as well as a limited experience of the variety, is not such judgment at once hasty and harsh? How was it, if such be a correct estimate of the quality of this Apple, that for two years in succession it secured the first prize in the competition at the Royal Horticultural Society's Fruit Show as the best flavoured fruit in a class in which some 30 dishes of many assumed high-flavoured varieties were shown and tasted, and last year both first and second prizes fell to Charles Ross. Very large fruits of this Apple produced by rich culture approach to Peasgood's in character. Fruits produced under ordinary conditions are of medium size, and more closely resemble Cox's Orange Pippin in flavour, and when the trees are older the flavour will further increase. *One of the Judges.*

Fruit Prospects in Scotland. There is an abundance of blossom on the Plum and Cherry trees in south-western Scotland this season; and especially on such varieties as the Early Rivers, Czar, Victoria, and Superb Greengage Plums; and the May Duke, Early Rivers, Black Eagle, and Morello Cherries. In my own garden those trees seem to have greatly benefited by a strong application of lime given at the end of last October to their fibrous roots. This will also be of great value to them during the crucial stoning season, especially as the trees have come into blossom nearly a fortnight later than in normal seasons, and thus escaped the frost. The beautiful Prunus Pissardii is at present making an effort, so far successful, to set its fruit. Several Pears, including the Early Crawford, and Apples, such as the Irish Peach and the Beauty of Waltham, are already in exquisite and fragrant bloom. *David R. Williamson.*

——The wintry weather which culminated in a snowstorm and a frost of uncommon severity on April 24 has done much greater harm to vegetation than was at first apparent. In many places it has wrecked the fruit crop and crippled the trees; especially is this the case in the north of Scotland, where I saw Laurels and other shrubs quite blackened. In our milder climate, Apricots and Figs have suffered most severely, but it is becoming every day more obvious that Apples and other fruits also have had the fruit-buds destroyed. Hardy Fuchsias, Moutan Paeonies, Japanese Maples, Pyruses, and many other plants which have passed unscathed through many hard winters are all less or more damaged. The flowers of Norway Maples have been dropping to the ground exactly like Gooseberries at an earlier date. *R. P. B., Tyninghame Gardens, Prestonkirk.*

Rhubarb.—A variety of Rhubarb that appeared to be an exceptionally strong grower and prolific in its foliage was shown at the meeting of the Royal Horticultural Society on April 14 last under the name of Dawes' Challenge. Apart from the remarkable vigour of these some three-years-old stools, with all their bulk of blanched petioles showing what strong Rhubarb roots are capable of producing, there was nothing remarkable in the variety. The stalks that were shown in bundles at the same time, when cut through, presented a white flesh rather than a red one, and that was held by the Committee to be a decided defect. This variety must not be confounded with Daw's Champion, a variety that has received the certificate of the R.H.S., and which is one of the earliest of Rhubarbs, producing fine deeply-coloured leaf-stalks that are coloured internally as well as on the skin. Deep colouring is always associated with flavour in Rhubarb, and is held as a most valuable feature in this plant. For market purposes, deep colour in the stems is indispensable, and, because of this, the richly-coloured, early maturing Hawke's Champagne has been the most widely grown for market sale. The older early varieties, such as Linnæus and Albert, appear to have been quite displaced by Hawke's Champagne, but Daw's Champion is even better than the last-named, and will in time occupy the highest place as a market variety of this fruit, for the successful market growers must have the best and earliest variety. With the exception of the new variety exhibited on the 14th ultimo, it is believed that the gardens at Wisley contain representatives of all the known varieties of Rhubarb, and this affords an admirable opportunity for estimating the relative values of each variety, in regard to earliness, colour, and cropping. In the case of Rhubarb for forcing, the capacity of the variety to reproduce its foliage rapidly is important, and no doubt a great deal of this quality depends upon the vigour of the crowns, which should not be too thickly planted, and the leaves should be unmolested during the summer season. Fifty years ago the best known varieties of Rhubarb seem to have been Victoria, then described as the "best," Tolbolsk, Gigantic—probably the same as Stott's Monarch—Buck's and Elford. Now we have probably some 20 or 30 varieties, of which Victoria is still the most favoured with cottagers, but not with market growers. The Crimson Winter or New Zealand Rhubarb does not seem to have been widely grown. Possibly, after a few years' growth here, it may accommodate itself to our seasons. With many gardeners the most popular Rhubarbs are The Sutton, Kershaw's Paragon, and Scarlet Defiance, all of which are undoubtedly fine varieties. *A. D.*

Humea elegans.—I was somewhat surprised to observe a correspondent recommending this plant to be placed in a warm structure during winter, because it succeeds so well in a cold pit among other plants which require merely enough heat to exclude frost, that I should imagine a low temperature is just what it requires. The Humea at one time was considered a particularly "miffy" plant, and one staged in a collection of stove and greenhouse plants, if presented in perfect condition, with foliage intact, made invariably a strong point. It is still a subject demanding very careful treatment, judging from the bare-stemmed plants which are all too common at the same time. I find it one of the easiest of plants to manage, the chief points being to keep it slowly growing without suffering a check from seed time to flowering. I find June quite soon enough to sow the seeds. As these germinate in a rather irregular manner, the tiny seedlings need to be withdrawn as they become large enough to handle, to be pricked off into pots or boxes. Once fairly started, the plants make roots abundantly, and they must be potted and re-potted before they become in the least degree potbound. Good plants are produced in 8 and 9-inch pots, the shift into these being made before winter sets in, and in spring, if extra large plants are required, a further shift

into 11-inch pots is essential. The benefit of a low winter temperature is that under such conditions not much water is needed, and there is perfect immunity from insect pests. But with the warmer, longer days of spring the plants require much water, and as the roots fill the soil manure water must be given without stint. When bedded out, it is essential to continue the application of manure water until the plants have taken to the soil, otherwise they are almost certain to perish, or, at the very least, to lose their foliage. I have occasionally had plants so late in blooming that they have been in good condition all through the winter, when they have been prized for room furnishing, though it must be conceded that the scent, which most people appreciate, is abhorrent to others, to whom it is reminiscent of a dirty pigstye. It may be added that there are good and better strains of the Humea, some being considerably brighter than others. *B.*

SWEET-SCENTED GREENHOUSE RHODODENDRONS.—We are not all favoured with the delightful climate of the extreme south-west of England where so many Himalayan Rhododendrons find a congenial home out of doors. Such being the case, some of them at least must in most districts be regarded rather as greenhouse than as hardy shrubs. For the development of some of the various Himalayan species such as R. arboreum, a large structure is necessary, but this does not ho'd good with regard to them all, and some of the species, and many of the garden hybrids obtained therefrom, may be flowered in a comparatively small state. Apart from their beauty, some of these garden forms bear flowers which possess a delicious fragrance, a feature that commends them to nearly everyone. The different garden varieties owe the greater part of their perfume to Rhododendron Edgeworthii, a very distinct species, remarkable for the dense, woolly tomentum with which the undersides of the leaves are thickly clothed. The flowers are large, widely expanded, and pure white, except for a blotch of yellow towards the base of the upper segments. Their perfume is delightful. As a rule, R. Edgeworthii is of somewhat straggling habit, to be accounted for by the fact that in a state of nature it frequently occurs as an epiphyte on the trunks of trees and has to stretch out towards the light. Next to R. Edgeworthii, the species that has played an important part in the production of these garden varieties is the compact-growing R. ciliatum, with blush-coloured flowers, more thimble-shaped than those of the preceding species. Other kinds that have also been employed are R. Dalhousiæ, R. formosum (or Gibsonii as it is often called), R. Veitchianum, and R. virgatum. One of the earliest hybrids possessing the delicious fragrance of R. Edgeworthii is Princess Alice, which was obtained by Messrs. Veitch as the result of crossing this just-named species and R. ciliatum. This variety has very fragrant blossoms, intermediate in shape and size between its parents. When first expanded, they are a good deal flushed with pink, but after a time become almost white. This was first shown by Messrs. Veitch, and a First-Class Certificate awarded it by the Royal Horticultural Society in 1862, but it still holds its own as one of the very best. R. fragrantissimum and R. sesterianum, both old varieties, suggest in general appearance a similar parentage, that is, if the forms now grown are the same as the original ones. I should say that the parents of these two varieties are R. Edgeworthii and R. formosum. A very popular garden variety with large white deliciously-fragrant blossoms is Lady Alice Fitzwilliam, of whose early history I have no record. It is, however, in every way a very desirable form. The largest-flowered variety of all with the delightful perfume of those previously mentioned is R. Forsterianum, raised, I believe, by Mr. Otto Forster many years ago. The parents are R. Edgeworthii and R. Veitchianum, the large, almost pure white flowers of which are remarkable for the attractive manner in which the edges of the petals are crisped. Within the last few years Messrs. Veitch have given us several opportunities to see the beauties of R. Veitchianum, for they have freely shown well-flowered examples at the spring meetings of the Royal Horticultural Society. In returning to R. Forsterianum, it may be noted that while the habit of the plant, at least, in a young state, is somewhat straggling, the flowers are magnificent. They are large, crisped, widely expanded, and pure white, with the exception of a slight yellowish blotch. From 20 to 30 years ago a group of sweetly-scented Rhododendrons raised and distributed by the late Mr. Isaac Davis, of Ormskirk, was much sought after, but of late they are not so generally met with. Probably this is owing to the fact that they are less vigorous growers than those previously mentioned. The Ormskirk seedlings bearing the names of Countess of Derby, Countess of Sefton, Duchess of Sutherland, Lady Skelmersdale, and Mrs. James Shawe, were obtained by the inter-crossing of R. Edgeworthii and R. multiflorum, this last a seedling raised by Mr. Davis from R. virgatum × R. ciliatum. Some at least of these hybrids are characterised by comparatively dwarf growth, and a free yield of blossoms when quite small. The flowers of these are all white, slightly tinged with pink on the exterior, but they differ in well-marked features from each other. All agree in having a delicious perfume. Since the death of Mr. Davis I have never met with the members of this section grown in quantity, and they are now difficult to obtain. Though not remarkable for its fragrance, mention of the Ormskirk-raised Rhododendrons suggests R. præcox (ciliatum × dauricum), for which we are indebted to Mr. Davis. That gentleman used to point out that, when first shown by him on March 12, 1861, it was only considered worthy of a commendation by the Floral Committee of the R.H.S., whereas time has proved that it well deserved the highest honours. An instance of the irony of fate is furnished by the fact that on the same day the variegated-leaved variety of Agathæa cœlestis was given a First-Class Certificate. *W.*

THE PERPETUAL-FLOWERING CARNATION AS A BEDDING PLANT.—The merits of the perpetual-flowering Carnation as a summer bedding plant are not generally recognised, notwithstanding that this type of the flower is superior for the purpose to the ordinary border Carnation. In many gardens Carnations are not utilised for summer bedding because they require to be planted in the autumn or very early spring, and thus preventing the planting of spring-flowering subjects. The perpetual-flowering Carnation may be planted in the open in May, and after the spring-bedding plants have finished flowering. At Messrs. Hugh Low & Co.'s Bush Hill Park nursery experiments have been conducted with the perpetual-flowering Carnation to test its suitability as a summer-flowering plant, and the results have proved that the best results are obtained from late-rooted cuttings, wintered in a cold frame, and planted out in May. Bushy plants, in 5-inch pots, with from eight to ten shoots, give satisfactory results. Plants which produced a crop of bloom during the early winter also did well, and excellent results were obtained from early-rooted cuttings, with from five to seven shoots, planted out from 3-inch pots. An important point is to have the growths from 3 to 4 inches long, so that when they are put out in May there will not be a long period before the flowers appear. Varieties specially suitable for flowering out-of-doors are: White Perfection, Lady Bountiful, Harlowarden, Harry Fenn, Robt. Craig, Victory, Mauvina, Floriana, and Enchantress; while Mrs. T. W. Lawson and its numerous sports are all suitable, but the flowering shoots are short. The cultural requirements are simple. Hoeing should be freely practised, and the plants should receive an occasional top-dressing, or application of liquid manure. A sharp spray with salt water will keep insects at bay. Experiments have also been carried out by Messrs. Low in the wintering of the perpetual-flowering Carnation in the open ground, under the same conditions as that given to the ordinary border Carnation. Excellent results were obtained in this direction, notwithstanding that the soil was of a rather heavy texture and somewhat damp. A few only of the plants died. Plants which had flowered during the summer months in the open, and were cut back in the autumn, withstood the severe weather of the past winter, and are now developing flowering growths. The varieties which did best were: Enchantress, Lady Bountiful, White Perfection, Robt. Craig, Harry Fenn, and Nelson Fisher. *Montagu C. Allwood.*

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

MAY 12.—*Present:* Mr. E. A. Bowles, M.A., F.L.S. (in the chair); Dr. A. Voelcker, Messrs. G. S. Saunders, H. T. Gussow, de B. Crawshay, J. T. Bennett-Poe, H. J. Elwes, W. C. Worsdell, E. M. Holmes, J. Douglas, and F. J. Chittenden (secretary). Visitor, Rev. A. R. Upcher, M.A.

Malformed Narcissus.—Mr. W. C. WORSDELL reported that he had examined the malformed Narcissus J. T. Bennett-Poe sent to the last meeting by Messrs. HOGG & ROBERTSON, and found that the flower exhibited signs of fasciation, but this was only partial, since the perianth segments were only nine in number, as were the stamens; there were, however, two normal ovaries, each with its full complement of three carpels. The style was somewhat flattened, and springing from its base was a branch which was probably a second style. This had become petaloid and tubular, and in the tube thus formed a third style had developed.

Fasciation in Narcissus.—Mr. J. W. ODELL sent flowers of Narcissus Emperor which had been produced after all the normal flowers in the bed had died off, and which were fasciated, some having flattened stems bearing at the apex three flowers, each on a separate pedicel, others having the fasciation carried farther, so that the flowers themselves were coherent.

Peloric Calceolaria.—Mr. H. TYSOE, of the Lodge Gardens, Bedford, sent flowers of Calceolaria showing regular peloria. All the flowers on the main branches of the inflorescences of two plants exhibited this phenomenon.

Primula.—Mr. DOUGLAS showed on behalf of the Right Hon. the Earl of WALDEGRAVE some flowers of the green Primrose, in which the corolla is virescent and the stamens are but imperfectly formed. Rev. A. R. UPCHER, M.A., of Halesworth, Suffolk, showed a large number of flowers of Polyanthus of large size and much substance, and many with a very distinct eye. The calyx was large and very broadly campanulate in most of the flowers. Mr UPCHER had started some 30 years since with the old "butter" Polyanthus, and had pollinated this with pollen from Primula sinensis and P. Auricula; but although considerable variation in many directions was observable in the flowers shown, the committee did not consider that there was any evidence that the pollen of these species had had any effect in producing the results obtained. Some of the forms had fringed petals, and others smooth-edged petals, the petals in some were remarkably broad, the "eye" was well marked, and contrasted with the remainder of the corolla in some, while in others the deep colour was suffused over the whole of the petals. The collection showed in a marked manner the variation obtainable in Polyanthus through cultivation without the introduction of new blood. Mr. BOWLES showed a number of flowers of P. officinalis from a wild source lacking the deep yellow spot which is usually to be found in the flowers of this species. He asked that others would make observations in order to note whether this was a common phenomenon or not.

Seakale disease.—Mr. H. T. GUSSOW showed a specimen of Seakale which had become rotten, one of a considerable number in a plantation in Norfolk, which he said had been attacked by a bacillus, at present undescribed, differing in certain characters from Pseudomonas campestris. He considered that the attack of the organism upon the Seakale had been made possible by the methods adopted in forcing the Seakale, and that the attack might have been prevented if air had been admitted by raising the Seakale pots somewhat above the soil level.

Intumescence in Brugmansia.—Mr. G. S. SAUNDERS showed a leaf of Brugmansia exhibiting small warty growths, known as intumescences, a condition brought about usually by lack of a proper balance between the amount of water supplied at the roots and the humidity of the air, and a proper regulation of temperature.

Amaryllis sp.—Mr. H. J. ELWES, F.R.S., showed a plant apparently allied to Amaryllis solandræflorum, but having a rose suffusion upon the perianth. The flowers are of very elegant form, and the plant appears to be rarely seen in this country.

Moræa iridioides var. Johnsonii. Mrs. J. L. RICHMOND, of Woodlands, Lustleigh, South Devon, sent a flower and leaf of the very beautiful variety Johnsonii of Moræa iridioides (*see Gardeners' Chronicle*, May 11, 1907, fig. 121). The flowers are considerably larger than those of the type or the variety Macleayi, and the foliage is upright instead of being fan-shaped; the bud was picked on May 7, and the flower was still almost perfect on the 12th inst. The seed from which the plant originated was brought by a lady (Mrs. JOHNSON) from the mountains of Ceylon, where it had probably been originally taken from South Africa.

BRITISH GARDENERS' ASSOCIATION.

MAY 12.—We are informed that at the last meeting of the executive council, held on the above date, Mr. Chas. Foster in the chair, 78 new members were elected and two candidatures were rejected. Questions affecting the payment of wages due to a Northampton member, and the alleged grievances of men at Kew were considered, and will come up for further report. Arrangements were made for the annual general meeting, which will take place at the Essex Hall on Wednesday, May 27, at 7 p.m. A very large meeting is anticipated.

ROYAL BOTANIC.

MAY 20.—An exhibition was held under the auspices of the above Society on this date. Tulips formed the chief feature of the display, and amongst other exhibits of note was a collection of Roses staged by Messrs. WM. PAUL & SON, Waltham Cross, who showed tall plants of rambling varieties about 9 to 10 feet high, including the pretty single blush-red Kathleen; Stella, with twisted petals; Claire Jacquier, of amber colour, changing to white; Grace Thompson, Lady Gay, Paradise, and other well-known sorts. There were also fine blooms of La France, Grace Darling, Étoile de France, Madame Durand, Dora, Marquise Litta, Souvenir de Madame Eugene Verdier, and Madame Jules Gravereaux. (Gold Medal.)

Messrs. J. PEED & SON, West Norwood, exhibited a group of Japanese Maples, with Richardia (Calla) africana and Clematis interspersed amongst them.

The Misses HOPKINS, Mere Gardens, Shepperton-on-Thames, had a pretty arrangement of rock-garden and other hardy flowers.

The Misses E. & M. KIPPING, Hutton, Essex, also made a pleasing exhibit of rock-garden plants.

Messrs. R. WALLACE & Co., Colchester, staged about 150 large vases of Tulips, including Gesneriana lutea, lutea pallida, Gesneriana Major, Orange Beauty, &c. (Large Gold Medal.)

Messrs. BARR & SONS, King Street, Covent Garden, were awarded a large Gold Medal for a grand exhibit of Tulips, which included the varieties James XIV., Tak van Poortvliet, Auber, Inglescombe Pink, Calliope, &c.

Messrs. R. H. BATH, LTD., Wisbech, put up a choice collection of Tulips, which included some fine new varieties. Giant, a large purple-mauve flower, with dark base, was very fine; Feu Brilliant, of a deep crimson colour, with a blue base; and Haarlem, a large flower of rosy-pink shade, were all of merit. (Silver-Gilt Medal.)

Messrs. HOGG & ROBERTSON, Dublin, staged an exhibit of Tulips, chiefly of the Darwin varieties, but cottage garden Tulips were also well shown. St. Brigid Anemones were included in the display. The flowers were all of the best quality. (Gold Medal.)

CERTIFICATES OF MERIT.

Rose "Paradise."—A pretty rambling variety with starry single flowers, the petals being white at the base, and shading to pink. Shown by Messrs. W. PAUL & SONS.

Tulip Psyche (Darwin).—A pink variety, with pale blue base, the large flowers being of good substance.

T. "Millet" (Darwin).—The colour is deep maroon-crimson; the blooms are large and of good substance.

T. Afterglow.—A cottage garden variety, the colour being yellow, shading to deep red. These Tulips were shown by Messrs. R. WALLACE & Co.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

MAY 11.—The usual monthly meeting was held at the Horticultural Hall, Vincent Square, Westminster, on the above date, Mr. Charles H. Curtis in the chair. Five new members were elected and one nominated. The amount paid for sickness during the past month was £25 12s. The amount of sick pay up to May in 1907 was £199 11s., and to the same time this year it was £154 8s., being less by £45 3s. Five chronic sick members and five other members are on the funds at the present time. The annual report and balance-sheet has been posted to all honorary and benefit members.

CATALOGUES RECEIVED.

GEO. COOLING & SONS, Bath.—Roses.

THOMAS KENNEDY & Co., Dumbries.—Bedding, hardy herbaceous, greenhouse, and other plants.

CLARK BROTHERS & Co., 65, Scotch Street, Carlisle.—Summer flowering plants and florists' flowers.

G. H. RICHARDS, 234, Borough, London.—Horticultural sundries.

W. PAUL & SONS, Waltham Cross, Herts.—Roses, Cannas, Phloxes, &c.

CLIBRANS, Altrincham and Manchester.—Bedding plants.

THE PARMITER PATENT SPRING WIRE TOOTH HARROW, for surface weeding, &c.

COLONIAL.

C. A. NORBLIUS, Gembrook Nurseries, Emerald, Victoria, Australia.—Fruit trees, ornamental trees, &c.

FOREIGN.

HARLAN P. KELSEY, Salem, Mass., U.S.A.—American hardy Rhododendrons and bulbous plants.

AMERICAN NURSERY CO., 150, Broadway, New York.—Trees, shrubs, Roses, perennial plants, &c.

JULES DE COCK, Villa des Lauriers, Meirelbeke-Gand, Belgique.—Indoor plants.

FRANZ DE LAET, Contich, Anvers, Belgique.—Cactaceous plants.

V. LEMOINE ET FILS, Rue du Montet 134, Nancy, France.—Greenhouse and hardy plants.

OTTO MANN, Leipzig.—New plants.

FRANÇOIS GUILLEAUX, 21, Rue de Cronstadt, Nancy, France.—Plants.

J. FEED. WESTENHOEFF, Sassenheim, Holland.—Bulbs and flower roots.

HOLLAND PLANT COMPANY, Boskoop, Holland.—Rhododendrons, Roses, Clematis, Pæonies, &c.

WILLY MUELLER, Naples, Italy.—New and rare plants.

YOKOHAMA NURSERY CO., LTD., London address, Craven House, Kingsway, London, W.C.—Hardy Japanese trees and shrubs.

J. C. TISSOT, 7, Rue du Louvre, Paris.—Horticultural sundries.

GEORG HARTMANN, "Lindenhaus," Niederhochstadt, a Taunus, Prussia.—Orchids.

GARDENING APPOINTMENTS.

[*Correspondents are requested to* ***write the names of persons and places as legibly as possible.*** *No charge is made for these announcements, but if a small contribution is sent, to be placed in our collecting box for the Gardeners' Orphan Fund, it will be thankfully received, and an acknowledgment made in these columns.*]

Mr. I. RODGERS, for the past 4 years and 8 months Foreman to Lady HOLMPATRICK, Abbotstown, Castleknock, Dublin, as Gardener to the Marquise CONYNGHAM, Slane Castle, County Meath.

Mr. C. GREEN, late Gardener to E. A. HANKEY, Esq., Norton House Gardens, Lacock, Wilts., as Gardener to H. FAVAGER, Esq., Baldon House, Marsh Baldon, Oxon. (Thanks for contribution to R.G.O.F. box.)

Mr. H. HUMPHRY, for the past 2 years Gardener to Lady MARY HOLLAND, Knebworth Hall, Royston, and previously Gardener at Triggens Park, Ware, as Gardener to the Right Hon. Lord LUDLOW, Lamport, Northampton. (Thanks for contribution to R.G.O.F.)

Mr. J. CHILCOTT, for 3 years Orchid Grower at Knowsley Hall, Prescot, as Gardener to Mrs. TAYLOR, Chipchase Castle, Warkworth-Tyne.

Mr. S. BURGESS, for the past 9½ years Gardener to J. T. FRIEND, Esq., Northdown House, near Margate, Kent, as Gardener to Mrs. LAUBER, Preston Hall, Aylesford, near Maidstone, Kent.

Mr. FRED. STANBRIDGE, for the past 3 years Gardener to Lord ERNEST HAMILTON, Shantock Hall, Hemel Hempstead, as Gardener to H. W. CARR, Esq., Bury, Pulborough, Sussex.

Mr. A. DAVIES, for 5½ years in the gardens, Oakmere Hall, Hartford, Cheshire (the last 4 years as Inside Foreman), as Gardener to H. C. BURDER, Esq., The Elms, Warrington.

MARKETS.

COVENT GARDEN, May 20.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—ED.]

Remarks.—French Cherries are arriving in half-sieves, and there are reports that the prospects of a heavy crop this season are good. There are English Gooseberries from Kent and the West of England. Strawberries are still cheap and the supply seems greater than the demand. Mushrooms are much cheaper owing to the warmer weather. Peaches are selling fairly well, but the supply of these fruits is ample. Trade generally is quiet.—*E. H. R., Covent Garden, Wednesday, May 20, 1908.*

Potatos.

Remarks.—Trade is slow and consignments are very small. New Potatos are arriving from Jersey, and next week there will be considerable consignments from this island; they are realising to-day (Wednesday) 17s. 6d. per cwt. *E. J. Newborn, Covent Garden and St. Pancras, May 20, 1908.*

COVENT GARDEN FLOWER MARKET.

During the past week trade has improved considerably. There is now a large demand for bedding plants. The hot weather has rapidly developed Roses, Carnations, and other flowers, which are all abundant.

Pot Plants.

Pelargoniums are the most prominent flowering plants. The show and decorative varieties have not much favour among London buyers, but they have a demand in the provinces. Among Zonals, F. V. Raspail is still one of the most prominent, Snowdrop and Albion are the best whites, and Hermione is now the best double white; Mrs. Lawerence and King of Denmark are the most popular salmon-coloured varieties. Semi double pink varieties do not seem to open their flowers well in the season, but there are several good single pink varieties, Mrs. French and Mrs. Brown Potter being favourites. King Edward, Paul Crampel, and Gloriation are "scarlets" of merit. Ivy-leaved varieties include Madame Crousse Galilee, Souvenir de Chas. Turner, and Mrs. Hawley. Galilee is largely used for decorations. Ordinary plants for window-boxes, etc., are worth from 6s. to 8s. per dozen, but extra well finished plants in 48's realise 15s. to 18s. per dozen. Autumn sown Mignonette is very good, and well-flowered samples of the spring sown plants are obtainable. Intermediate Stocks are still procurable in well grown plants. The common Musk is good; Harrison's variety is not so much appreciated as it was a few years ago. Saxifraga pyramidalis is very fine. Roses include fine specimens of Hiawatha, Sweetheart, Dorothy Perkins, and other Ramblers. The hybrid perpetuals are also very good. Yellow Calceolarias are now procurable. There is an improved dwarf type of the yellow Chrysanthemum segetum. Plants of Marguerites can be had in various sizes. I have not yet seen any of the yellow variety. It is remarkable that we do not see any new varieties of Fuchsias in the market; such sorts as Rose of Castile, Mrs. Hextesbury, Arabella, Gertrude Pearson, Scarcity, and other old sorts remain favourites.

Bedding Plants.

Most growers of hardy flower roots still have large stocks on hand. Pansies and Violas sell fairly well, but the trade is beginning to fall off. All summer bedding plants are well supplied. Boxes of plants are considerably cheaper than they were a few years ago.

Cut Flowers.

Spanish Irises are abundant and cheap. English growers should cut them before they are very far advanced, as they would be more satisfactory to buyers; those from abroad are cut before the first flowers are open, and they quickly develop their buds after they are put into water. Poppies should also be cut before the flowers are expanded. Sweet Peas are now abundant in various colours. Narcissus poeticus and the double white variety are abundant. Many Roses are sold at very low prices, and the Carnation trade is nearly as bad. Liliums have developed rapidly since the hot weather set in. L. longiflorum is very fine. Callas are abundant and cheap. Lily of the Valley from the open ground is now plentiful. *R. H., Covent Garden, Wednesday, May 20, 1908.*

DEBATING SOCIETIES.

GUILDFORD AND DISTRICT GARDENERS'.—At the fortnightly meeting of this association, held on Tuesday, May 5, under the presidency of Mr. W. Hogsden, a lecture on "Water Gardening" was given by Mr. D. Watson, of Sutton Place Gardens. The lecturer gave details upon the formation and arrangement of water-gardens. He also stated the names of many of the more suitable aquatic and bog plants and gave hints on their cultural requirements. The planting and arrangement of shrubs and plants for effect in large masses near to the water-garden were also dealt with by the lecturer.

WARGRAVE AND DISTRICT GARDENERS'.—At a recent meeting Mr. E. Young, of Welford Park Gardens, Newbury, gave a short address on "The Cultivation of the Gloxinia." The lecturer referred to the methods of propagation by seed, cuttings and by leaves, describing minutely every detail for successful culture. The various ingredients used in the potting soil, the operation of watering, syringing, shading, and the use of artificial manures were described by Mr. Young, and he showed photographs of plants he had cultivated, some having as many as 60 flowers.

THE WEATHER.

The Following Summary Record of the weather throughout the British Islands, for the week ending May 16, is furnished from the Meteorological Office:—

GENERAL OBSERVATIONS.

The *weather* was generally unsettled, with much cloud, and more or less rain on several days. Thunderstorms or thunder only occurred in some parts of the kingdom on every day except Sunday most commonly about the middle of the week.

The *temperature* was rather above the average in the east and west of Scotland, and in the north-east and east of England, but rather below it elsewhere. The highest of the maxima were registered early on the 11th or 12th at several stations, but on the 16th generally. They varied from 67° in Ireland S., and 66° or 65° in most other districts to 60° in Scotland N. The lowest of the minima, which were recorded on rather variable dates, ranged from 31° in England S.E. (at Marlborough on the 11th) and 32° in the Midland Counties (at Cirencester on the 11th) to 37° in Ireland, Scotland W., and England N.E., and to 46° in the English Channel. The lowest of the grass minima reported were 27° at Cambridge, 29° at Crathes and Markree, and 30° at Balmoral, Oxford, Greenwich, Tunbridge Wells and Wisley.

The *mean temperature of the sea.*—Compared with the corresponding week of last year the water was warm on the north-east coast of Great Britain and cold in almost all other localities. The actual figures for the period ranged from 52·4° at Margate, 52·3° at Plymouth, and nearly 52° at Ballyglass and Seafield, to 45·8° at Bournemouth, and to 44·7° at Lerwick.

The *rainfall* was less than the normal in Scotland, the north of Ireland, and the north-west of Great Britain, but more elsewhere.

The *bright sunshine* was less than the average in all districts, as well as at almost every individual station. The percentage of the possible duration ranged from 39 in the English Channel and 37 in England S.W. to 32 over a large part of England and in Scotland N., and to 31 and 29 respectively in Ireland S. and N.

THE WEATHER IN WEST HERTS.

Week ending May 20.

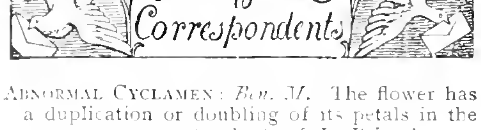
Three very warm days.—The first two days of the week were cold, but since then the weather has been unusually warm for the time of year. On the coldest day the temperature in the thermometer screen did not rise above 52°, whereas on the two warmest days the highest reading was 72°. The nights were all more or less warm. The ground is now 3° warmer at 2 feet deep, and 5° warmer at 1 foot deep than is seasonable. The first three days were wet, but since then the weather has remained fine. The sun shone on an average for 5¼ hours a day, or for half an hour a day less than a seasonable duration. The winds were as a rule light during the week. The atmosphere was very humid in the early part of the week, but the last few days the air has been very dry. A Blenheim Pippin Apple growing in my garden came first into flower on the 15th which is 10 days later than its average date for the previous 22 years, and later than in any year since 1888, or for 20 years. *E. M., Berkhamsted, May 20, 1908.*

SCHEDULES RECEIVED.

Women's Agricultural and Horticultural International Union's exhibition and sale of farm and garden produce at the Royal Botanic Gardens on Wednesday, July 15, 1908.

Winchester Horticultural Society's autumn show, to be held on Tuesday and Wednesday, November 17 and 18, 1908, at the Guildhall, Winchester.

Hanley Floral Fete will be held on July 1 and 2 in Hanley Park. The show will be the 12th in succession, and efforts are being made by the management to make the show a record one. A silver challenge cup is offered this year for the first time for the best trade exhibit. The secretary is Mr. William Poulson, Town Hall, Hanley.



Abnormal Cyclamen: *Ben. M.* The flower has a duplication or doubling of its petals in the manner common to plants of the Primulaceae.

Albino Form of the Scarborough Lily: *F. D.* An illustration of a white variety of Vallota purpurea was given in the *Gardeners' Chronicle*, August 27, 1904, p. 150, from a photograph sent us by Mr. James Whitton, Superintendent of Parks, and Curator of the Botanic Gardens, Glasgow. If you will refer to the text that accompanied the picture you will find much interesting information on White Vallotas.

Begonia Gloire de Lorraine: *J. C.* This plant may be easily trained into pyramidal shape. Place a central stake in the pot and train to this the main shoot, looping up the side branches and pinching any that require it in order to ensure a proper balance of growth.

BOOKS: *R. G.* The *Illustrations of New South Wales Plants*, by J. H. Maiden, is published under the authority of the Government of the State of New South Wales. It may be obtained from William Appleyard Gullick, Government Printer, Sydney, price 3s. each part.

BULBS FROM HOLLAND: *A. J. B.* The specimen which you sent us, and which you received from Holland for Snowdrops, is Ornithogalum nutans. This plant is often found as a "rogue" in bulb gardens.

CORRECTION. At the meeting of the Royal Horticultural Society, held on May 12, Messrs. R. H. Bath, Ltd., Wisbech, were awarded a Silver Flora Medal for an exhibit of Tulips and Narcissi and not a Bronze Banksian as stated in our report.

GARDENING EMPLOYMENT IN THE UNITED STATES: *G. W.* In our issue for February 2, 1907, p. 80, particulars are given by a gardener who had recently returned from America on the conditions of gardening employment in that country. He stated that the wages for head gardeners are from $50 to $100 per month, with house and coal. Situations in private gardens are hard to obtain, and an establishment employing five or six men is considered a large one. If you decide to go, do not buy any special clothes, but take what you happen to possess. Leave your hob-nailed boots behind; you will find they are of no use there, being too cumbrous. If you have no friends, you must have £6 in your pocket on landing. On arriving the first thing to do is to place your name on every employment register you can, whether of florist, seedsman, or nurseryman.

HOLLIES: *S. T.* It is not unusual for a few leaves of newly-planted Hollies to turn brown and fall off. In such cases all shrivelled shoots and branches should be removed, and if you can place tiffany or any similar light material over the specimens as a protection against the sun's rays and winds, so much the better. The covering material should be kept moist until the Hollies make new growth.

HORTICULTURAL TRAINING FOR A YOUTH: *W. F. L.* The best training for a youth who wishes to learn gardening is to commence in a good garden, under the care of an efficient gardener. He will thus begin at the very bottom of the profession and be taught all the duties, however small, and a knowledge of these minor duties will be of great assistance to him, should he afterwards reach a responsible position in the profession. There are, of course, several schools where gardening is taught, including that at Wisley, which is under the auspices of the Royal Horticultural Society. Full particulars for admission as students to the Wisley gardens can be obtained from the Secretary of the Royal Horticultural Society, Vincent Square, Westminster.

INSECTS: *J. G. B.* The small white insect found in the soil is one of the "springtails" (Lipura fimetaria, Linn.). It is very common, and often swarms in soil heavily charged with manure or leaf-mould. The insect on the Picea shoot is apparently Chermes corticalis, one of the Aphidæ. The micro-photograph you sent is very good.—*G. W. T. (subscriber).* The grub is known as the "Leather Jacket" or larvæ of the Crane Fly (Tipula sp.). You may trap them by placing pieces of turf between the infested plants. Gas lime is injurious to these pests, but it cannot be applied to land under cultivation.—*H. R.* The grubs you send are a species of Tipula. See reply to *G. W. T.*

MUSHROOMS DISEASED: *G. A.* Your Mushrooms are affected with a disease caused by Hypomyces perniciosus. According to the Leaflet No. 139, issued by the Board of Agriculture, numerous toadstools and other fungi suffering from the parasitism of different kinds of Hypomyces are common in woods and pastures every season, and spores are probably introduced into the Mushroom bed along with the manure or road sweepings commonly used. In some instances it is certain that the spawn is infected before it is placed in the Mushroom bed. In such cases, when the spawn commences to "run," the threads, instead of having a clear and sharp outline like white cord, present a fluffy appearance, due to the presence of the parasite on the surface of the strands; the branches are also much fewer in number than when the spawn is healthy and growing vigorously. Under such circumstances the entire bed should be removed before the parasite produces spores; otherwise, if the house becomes thoroughly infected, common experience has shown that the disease is exceedingly difficult to eradicate. When infection occurs through the introduction of spores into the house by wind or other causes, the disease may be confined to certain portions of the bed, and the prompt removal of infected Mushrooms as soon as the slightest symptoms are observed may check the disease from assuming the proportions of an epidemic. After removing the soil and manure of an infected bed, great care should be taken in cleansing the tools, boots, and even clothing; otherwise there is great risk of infecting other beds. Rejected soil and manure should be at once removed from the neighbourhood of the Mushroom beds. They may be applied to the land, as the contained spores, so far as is known, can only develop on some kind of fungus, and do not attack any other cultivated crop. When a house or other structure in which Mushrooms are grown has become infected, it should be completely emptied and thoroughly sprayed, both roof, walls, and floor, three times at intervals of ten days with a solution of sulphate of copper—one pound of sulphate to 15 gallons of water. During this period of spraying the house should be kept warm and moist, for the purpose of favouring germination of the spores of the parasite, which are destroyed with greater certainty when growing than when in a resting condition.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. *Correspondents not answered in one issue are requested to be so good as to consult the following numbers.*

FLOWERS: *P.* Ribes speciosum, the Fuchsia-flowered Gooseberry.

PLANTS: *W. F. B.* Erysimum cheiranthoides.—*J. B.* Senecio auriculatissimus, a species from British Central Africa. The fact that several nurserymen have this plant amongst Senecio (Cineraria) stellata with the idea of crossing the two will explain the appearance of your plant.—*R. S. P.* Moræa bicolor.—*W. K.* Lamium maculatum.—*A. J. W.* Schizostylis coccinea.—*E. F.* 1, Onychium japonicum; 2, Cyrtomium falcatum; 3, Cyrtomium fortunei.—*W. E. S.* 1, A small Odontoglossum loochristiense; 2, O. Andersonianum Rucklanum; 3, O. Andersonianum hebraicum; 4, O. Andersonianum lobatum; 5, O. Coradinei, very good variety; 6 and 7, O. Andersonianum, good varieties; 8, O. Adrianæ.—*Crispum.* A very pretty Odontoglossum, probably not a true O. crispum, for, like many which have been imported from the district from which O. Adrianæ comes with O. crispum, there is a slight trace of O. Adrianæ in it, and it would probably be more correct to name it O. Fascinator (crispum × Adrianæ).—*H. W.* Lælia purpurata, a very good, white-petalled variety; and Odontoglossum citrosmum, which you have grown remarkably well, and therefore it has produced a fine, branched inflorescence.—*Alpha.* 1, Cochlioda vulcanica; 2, Odontoglossum gloriosum; 3, Odontoglossum blandum; 4, Oncidium abortivum; 5, Aerides falcatum.—*P. P. S.* 1, Adiantum Capillus-veneris cornubiense, A. Capillus-veneris Mariesi; 3, A. Pacotii; 4, Lantana, garden variety; 5, Billbergia nutans. You should fix the numbers to the specimens.—*M. W.* 2, Begonia Ingramii; 4, B. parvifolia; 5, Pteris serrulata cristata. Specimens of the other plants should be sent again when in flower.—*G. D.* 1, Next week; 2, Conopodium denudatum.—*W. P.* Erica vagans white variety, Pyrus betulæfolia.—*Weekly Reader.* The form of Odontoglossum crispum sent is very distinct. The marking on the labellum is seldom seen so effectively displayed as in your specimen.—*R. R.* 2, Sedum Telephium; 3, Agathæa cælestis; 4, Juniperus chinensis; 5, Lonicera Xylosteum; 6, Mercurialis perennis; 7, probably a Spiræa (send when in flower).—*A. D.* 1, Lepidium Smithii; 2, Pedicularis sylvatica; 3, Polygala vulgaris; 4, Genista species; 5, not recognised.—*G. M.* 1, Escallonia macrantha; 2, Manettia bicolor; 3, send better specimen and state whether a greenhouse species.

PRIMROSE: *W. M., Naples.* The most similar plants in commerce to the flowers you have sent us are the bunch Primroses. Thanks for the specimens of Calanthe discolor.

SEED-PRODUCING POTATOS: *T. T.* We do not know any modern variety of Potato that produces seed freely. Many years ago some varieties did seed abundantly, but they were not good croppers. If the varieties were to seed freely they would simply reproduce themselves from seed. To obtain new varieties cross-fertilisation is necessary, and this can only be brought about by artificial pollination. You will find Puritan, Beauty of Hebron, Sir John Llewellyn, and Royal Kidney to flower freely, but none produces seed unless flowers on them be specially pollinated by hand, and to obtain new varieties the pollen must be taken from the flowers of another variety. Pollen is so difficult to obtain that it is not an easy matter to get sufficient to effect fertilisation.

SOIL FOR ANALYSIS: *J. H. B.* If you will send a sample to Dr. Voelcker, of 22, Tudor Street, London, E.C., he will undertake an analysis for you. His fee is reduced in the case of any persons who are members of the Royal Horticultural Society.—*G. L.* Our fungus expert reports that there is no disease present in the plants, and suggests that the trouble is in the soil. For particulars of soil analysis see reply to *J. H. B.*

STRAWBERRIES DISEASED: *Agricola and J. R. F.* Your plants are affected with the Strawberry mould disease that was described and figured in the *Gardeners' Chronicle*, July 16, 1904, p. 35. The fungus causing the complaint is Botrytris cinerea, a pest that is responsible for many diseases in cultivated plants.

SULPHURIC ACID REFUSE: *Interested.* Do not mix this corrosive substance with your manure, as this strong acid is fatal to plant life, and it may also have formed compounds that are highly injurious to vegetation. Try its effect as a weed killer on the garden paths.

TULIPS DISEASED: *J. S.* Your bulbs are suffering from a disease caused by Botrytis cinerea, a fungus often referred to in our columns. No remedy is known for the disease, and it is essential to destroy all affected bulbs to prevent the disease from spreading.

VINE LEAVES: *J. E.* There is no disease present in the leaves. Their discoloration and subsequent falling must be due to some error in culture. Have you applied too strong doses of manurial stimulants at the roots?

WEEVILS EATING ROSE BUDS: *T. C.* The insects you send are the common clay-coloured weevils. You should continue to hunt them at night time with a lantern. Spread a white cloth beneath the trees and shake the bushes, as these insects fall immediately a bright light is flashed near them. As regards poisoning them, we do not think quassia extract would be sufficiently strong, but you might try one of the arsenical compounds, such as Paris Green or London Purple. These mixtures can be sprayed on to the foliage by means of an ordinary syringe.

THE CRIMSON VARIETY OF CYTINUS HYPOCISTIS L.

I WAS delighted when staying at Hyères (Var) during last April to come across the beautiful little parasite of the Rock-roses. For some reason the Cytinus appealed to my zoological prepossessions. It is more like some tropical Anthozoon (coral) than a genuine leaf-bearing, root-and-branch-producing plant.

I found the commoner variety of the Cytinus, with orange-coloured bracts and yellow flowers, growing on the white-flowered Cistus, with sticky, narrow leaves. A second white-flowered Cistus, with broader, sage-coloured leaves, is nearly as common on the hills about Hyères as *C. monspeliensis*. I take it to be *C. salviifolius*, and I found the orange and yellow Cytinus on the roots of that species also.

But here and there were tracts of the *Maquis*, where the beautiful Cistus, with large, pink flowers, was predominant. It is apparently called *C. albidus*, a name which refers not to the colour of the petals, but to some other part of the plant. On the roots of this pink-flowered Cistus I found, in some 15 instances, the carnation or crimson variety of Cytinus, which is an even handsomer thing than the commoner orange variety. My specimens had carnation-coloured bracts and pure white flowers, and were stronger and more fleshy than the orange and yellow variety which I found on *C. monspeliensis* and *C. salviifolius*.

It certainly was the case within my limited experience that the carnation-coloured variety grew on the roots of the *pink*-flowered Cistus only, and that the orange and yellow variety grew on the *white*-flowered Cistus (of two species) only. If this observation were established as a definite law, it would indicate a bio-chemical connection of the rich carnation colour of the parasite with the pink pigment of the flowers of the host, and would have an interesting bearing upon the question of the pre-formation of a colourless chromogen substance and its storing in the root of the pink-flowered species of Cistus, whence it would be extracted and chemically developed into full carnation-glory by the root-parasite Cytinus.

With the kind assistance of Dr. Rendle, of the Natural History Museum, I have looked up what has been written on the Mediterranean Cytinus. It appears that, whilst the normal Cytinus Hypocistis L. has orange-coloured bracts and yellow flowers, a red variety has been recognised as var. rubra by Clus and var. kermesinus by Gussoni, whilst one author has proposed to consider the red variety as a distinct species *C. Clusii*. Arcangeli (*Atti. Congress Internaz. Botan.*, Florence (1874), published 1870, p. 155) has published a valuable anatomical account of Cytinus, as well as a discussion of its varieties and the hosts they frequent. He states that the red variety, which he calls var. kermesinus, grows on Cistus villosus in Tuscany. This is a red or pink-flowered Cistus, and is a synonym of *C. incanus*, whilst the pink-flowered *C. creticus* is a sub-species of the same. So far, Arcangeli's statement is in favour of the notion that the red carnation colour of the parasite may be due to the "chromogen" of the host plant. He, however, goes on to say that, where *C. monspeliensis* and *C. salviifolius* occur (that is to say, on the Ligurian Riviera), he always found the orange and yellow Cytinus on *C. monspeliensis*, and "only once" on *C. salviæfolius*. He further states that when he found Cytinus on *C. salviifolius* it was always, with this one exception, the red variety Cytinus Hypocistis var. kermesinus. If that is a correct observation, it makes an end of my suggestion. It is, however, possible that the question was not one which pressed itself on Arcangeli's attention, and he might have, by an oversight, assigned specimens of Cistus albidus without the inflorescence to the white-flowered *C. salviifolius*.

Perhaps some of the readers of this journal may be able definitely to settle the matter, now or at a future date.

I may add that, whilst my specimens of the red variety of Cytinus Hypocistis all showed carnation-coloured bracts and white flowers, it is stated that the flowers are sometimes also tinged with red. I have also seen a figure of the orange and yellow commoner variety, in which the corolla is represented not as pure yellow, which it certainly was in all my specimens, but as being partly flaked with orange. *E. Ray Lankester, May 20.*

THE BERLIN BOTANICAL GARDEN.

(Continued from page 327.)

THE collections under glass are exceptionally rich in species. Some of the groups, for example the Australian, South African, and tropical African, being far richer in number of species than are to be found elsewhere. The houses stand on high ground on the north side of the garden. They are divided into two departments, namely the nursery department where the plants are cultivated, and the show department. The public are not admitted into the former except by special permission. There are 12 spacious span-roofed houses devoted to this nursery work, and they are connected by corridors, so that in the coldest weather there is no difficulty in working them. In addition to these houses, there are three long, spacious pits, two of which are devoted to the cultivation of decorative greenhouse plants, the other serving as a store-house for plants requiring shelter in winter.

The show houses are grouped on an eminence not far from the nursery houses. There are 15 of them of various sizes arranged roughly in the form of a rectangle, and connected with each other so that visitors may go the whole round without having to go into the open air, an arrangement which is very advantageous in winter. These houses are constructed so as to admit the maximum amount of light, the sash bars being thin iron, but it must be difficult to maintain them at the required temperature during very frosty weather. There are double sets of doors at all the entrances from the outside.

The heating mechanism for the whole of these houses may be described as a new invention. Four large boilers erected in a roomy "machine house" supply the steam, which is led by steel pipes to the different groups of houses, where it passes into small tanks of water; and this, after it has been thus heated, circulates through hot-water pipes in the ordinary way. The arrangement of pipes, valves, tanks, &c., is such as no doubt may appeal to the engineer, but it looks far too costly and complicated to please the gardener. However, it works satisfactorily so far as the supply of heat is concerned. The great Palm house is heated by a complete circle of radiators situated in an open chamber extending all round the house below the ground level. All the houses are connected by an underground tunnel which is kept carefully locked against interfering persons, and it is used by the stokers at night so that they need not go through the open garden, which is guarded by two very large and savage dogs let loose every evening. These dogs have such a reputation that no one would dare to venture into the garden after closing time.

The Palm house is a large, elliptical-domed structure, 150 feet long by 80 feet wide, its height being 78 feet. All the plants in it are planted out in beds and borders, there being no stage of any kind. Tropical climbers are trained on the largest trees rather than against the glass, the aim being to produce as natural an effect as possible. The heating chamber and ventilating machinery are screened from view by means of a rockery, from the top of which is a waterfall, the water running down

through irrigating channels and serving the purpose of keeping up a moist atmosphere. A span-roofed house for Aroids, not yet finished, adjoins the Palm house, and from this the visitor passes into a large pavilion, 40 feet square, in which tropical dicotyledonous plants are planted out in the central portion or grown in pots on stages round the sides. Next to this is the Orchid house, 60 feet long and 20 feet wide, filled with tropical Orchids, many of them exceptionally fine specimens. From this house we enter another pavilion, in which Musas and other striking monocotyledonous plants are grouped. Following this is the house of Bromeliads, a very large collection being maintained. Then come the Ferns, beautifully grown and effectively grouped. The Victoria House is still in course of construction. The visitor passes on into two large houses filled with Cacti and other succulents, by far the best collection I have seen in any garden, its extent and condition being truly astonishing. Owing to the brightness and warmth of the Berlin summer, many of the succulent plants are placed outside from June till September. Tropical economic plants are a special feature at Dahlem, and they are cultivated with conspicuous success. Passing on to the houses containing what are known as greenhouse plants, there is first an Australian house, already so full as to be overcrowded; in fact, this is the condition of all the cooler houses during the winter, the plants they then contain being accommodated outside in summer. The temperate house stands by itself. Compared with the gigantic structure at Kew, it is small, its dimensions being 130 feet long, 60 feet wide, and 50 feet high. The general opinion is that it is too high for its width. It is filled with grand specimens of tree Ferns, Araucarias, Damaras, Acacias, and other plants such as are to be seen in houses of this character. To an Englishman, it is surprising to find that the common Holly, Cedar of Lebanon, and Araucaria imbricata must here be housed under glass in winter. *J. G. W.*

(To be continued.)

LEWISIA (CALANDRINIA) COTYLEDON.

FLOWERING for the first time in cultivation in this country, this new addition to a most interesting genus has proved an attractive plant. Altogether distinct in habit from all the other species of Lewisia or Calandrinia, this plant forms a rosette of leaves not unlike those of Saxifraga Cotyledon, without the white margin, and with crisped edges. The rosettes are about 4 inches in diameter, while the spathulate leaves are fleshy, and about 1 inch across at the widest part. The stem, like the leaves, is fleshy, 4 to 6 inches high, freely branched, and bears numerous flowers, several of which are open together. The 9 to 10 petalled flowers are about 1¼ inch in diameter, the petals being rose coloured with a broad white margin. The seven orange-coloured stamens have their white filaments more or less coherent at the base, while the sepals are also coherent and beautifully fringed like the bracts with reddish, glandular-tipped hairs. Plants of this beautiful species were received rather more than a year ago, having been collected in the Siskyon Mountains of Northern California, where it is said to be found growing on well-drained, rocky slopes, with a southern exposure. So far, Lewisia Cotyledon has been grown in a pot in a cold frame, but it is probably as hardy as any of the other kinds, provided that it is planted in a suitable position. Taken as a whole, the members of this genus are somewhat capricious in cultivation, but they are well worth a little care and attention on account of the beauty of their flowers. The best position for them is one exposed to full sunshine, planted in a mixture of loam, leaf-soil, and sand, with plenty of good-sized stones mixed with the soil. Another important point is to keep them as dry as possible in winter. *W. I.*

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM CRISPUM "LYNWOOD."

MR. H. HADDON, gardener to J. J. Neale, Esq., Lynwood, Penarth, sends a flower of a pretty, heavily-blotched O. crispum, taken from an inflorescence bearing 10 flowers. As the plant is a small imported specimen, it may be expected to develop flowers of still greater beauty. The flower is of good shape, the sepals and petals equally broad, and the lip proportionately showy. The flower is white, slightly tinged with purple on the sepals, which also have several large purplish-red blotches. The petals have eight to ten purplish-red blotches, and the lip bears a large one of the same tint in front of the light yellow crest, the whole being evenly distributed over the surface of the flower.

ODONTOGLOSSUM EXIMIUM "CENTENARY."

(ARDENTISSIMUM × CRISPUM, BLOTCHED VARIETY.)

THE upper three flowers of a strong inflorescence of this gorgeously-coloured Odontoglossum is sent by Mr. W. Stevens, gardener to W. Thompson, Esq., Walton Grange, Stone, Staffordshire, who considers it one of the best and showiest Odontoglossums in the collection under his care. It is a finely-formed flower, with almost equally broad sepals and petals, the latter having an extended crimped and fringed margin. The ground colour of Odontoglossums of this section is white, but this might be more correctly described as having the sepals and petals of a deep mauve-purple, as bright on the backs of the segments as on the front, the broad margins being white. The large labellum bears distinct evidence of O. Pescatorei, obtained through O. ardentissimum, the front being pure white, and the crest bright yellow with claret-coloured blotches around it. The upper side of the column is red, and the whole flower one of the most attractive of the many showy hybrid Odontoglossums.

ODONTOGLOSSUM FASCINATOR.

FROM the gardens of T. H. Lowinsky, Esq., Tittenhurst, Ascot, Mr. Joseph Timson sends a very pretty spotted Odontoglossum, which appeared among a small lot of imported Odontoglossum crispum purchased at Messrs. Protheroe and Morris' Rooms. The flower is white, densely spotted with claret-red, a lilac shade showing through from the colour at the backs of the sepals. It is just intermediate between O. Adrianæ (crispum × Hunnewellianum) and O. crispum and identical with some of the forms of O. Fascinator (Adrianæ × crispum), raised by Messrs. Charlesworth & Co., Heaton, Bradford, who first showed a selection of them at the Temple Flower Show, 1905. Without considering this cross, the flower of the imported plant would be very puzzling as it approaches closely to a spotted O. crispum, and bears little trace of the crimped and folded lip of O. Hunnewellianum seen in O. Adrianæ. There are doubtless many specimens of this pretty secondary hybrid in gardens, and probably a few among the varieties which have passed as O. crispum. A well-formed variety of O. Fascinator, distinctly blotched with cinnamon-brown, has recently flowered in the gardens of Sir Trevor Lawrence, Bart., K.C.V.O., Burford.

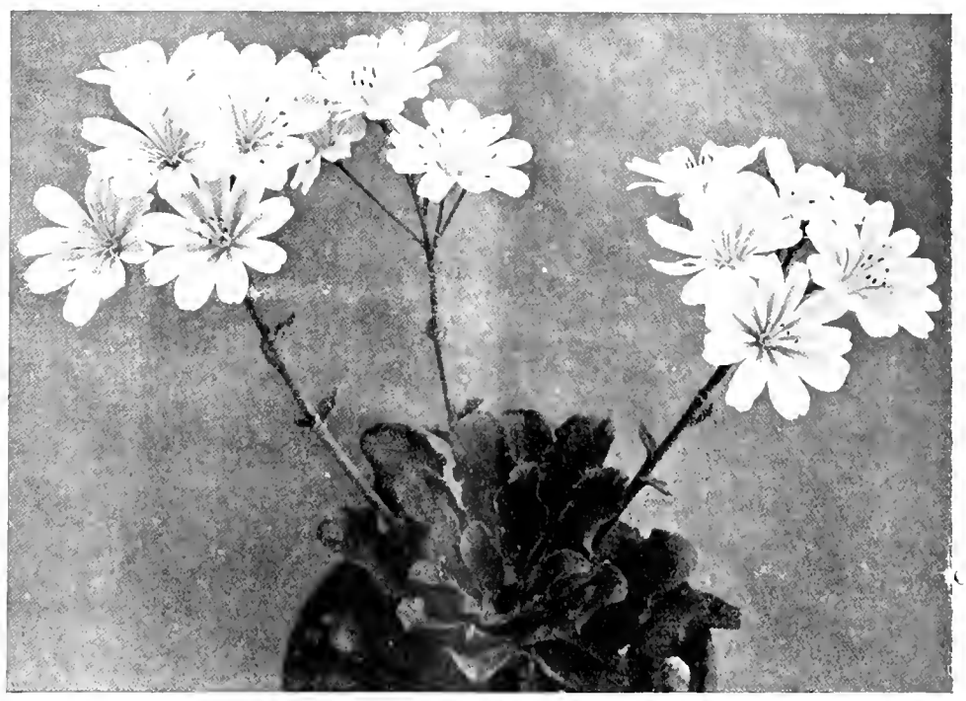

FIG. 151.—LEWISIA (CALANDRINIA) COTYLEDON, WHICH HAS RECENTLY FLOWERED, FOR THE FIRST TIME IN THIS COUNTRY, IN THE ALPINE HOUSE, KEW.

PLANT NOTES.

DENDROMECON RIGIDUM.

THIS rare Californian tree Poppy requires a sunny position, a well-drained soil, and shelter from the wind. Probably the plant would prove hardy in this country, or, at the most, lose the less well-ripened ends of the shoots from frost, unless slightly protected by Fir branches, &c. The natural season for flowering is June, but it may be obtained in bloom quite early in the year if grown under glass protection. The flowers are clear yellow, single, salver-shaped, and from 2 to 3 inches in diameter. The plant is raised from seeds, and it is necessary to sow these as soon as they ripen. It can also be propagated by means of cuttings, but this is a troublesome business. *M.*

TREES AND SHRUBS AT BATTERSEA PARK.

In no other public park in the metropolis is so large a collection of exotic trees and shrubs to be found as in Battersea Park, and at no other season than the present is the observer so well able to note the various shades of green in the foliage. I may mention a few of the more striking in leaf colour. Pale yellow is seen in Virgilea lutea, of which species of low-growing tree there are several in conspicuous positions, one being adjacent to the sunken panel garden at the north-west corner of the park. In the American Plane tree (Acer platanoides occidentalis) the young foliage is of a distinctly yellowish-green; and A. p. orientalis has leaves of a light green tint; those of Ailanthus glandulosus are of a golden brown, very distinct in tint, and appearing in large bundles; the foliage of the common Poplar trees, too abundantly in evidence on the islands in the lake, is striking in its brown colouring. The Kilmarnock Willow is a late-leafing tree, now beginning to unfold its buds, whilst the common Weeping Willow is already covered with its pendant shoots of the freshest green. A tree of Broussonetia papyrifera, growing on the lake side on the south side of the park, shows as yet (May 19) no sign of expanding leaf buds. The common Lime is in full leaf, but the leaves have not arrived at their full size, and the trees have, therefore, a less dense appearance than will be the case in summer. Of Pavias there are a few showing their brilliant spikes of scarlet and pink-coloured flowers; the red-flowered Horse Chestnuts in warm positions are loaded with flower-spikes.

Against the lighter tints of the deciduous trees the Hollies show nearly black by contrast, more especially the Hedgehog variety of Ilex Aquifolium. Ilex latifolia is pushing its new growths and the bushes of it are covered with the small white conical flower-heads. Young specimens of Salisburia adiantifolia have taken firm root, and are likely to grow into symmetrical forms, being seedlings, and not from cuttings or layers. Sombre-looking common Yew bushes have tender, green, new shoots, a tint they will keep till the end of July. White-flowered Lilac is blossoming freely where the sun has free access to the plants. In shady spots this variety is not so satisfactory. Persian Lilac is delightfully free in most parts of the park wherever it is given space for development and freedom from overhanging trees of large growth. Hawthorn bloom, in pink, scarlet, and white, is going to be a feature, and the flowers are expanding, hastened by the hot suns of the last few days. The Box bushes, now making new growth, exhale a most agreeable aroma. A tree of Magnolia conspicua in the "Sub-tropical Garden," is covered with its white, cup-like blossoms. It is a pity there are not more Magnolias planted in this park. Mention may be made of M. Soulangeana, a cross between M. Yulan and M. obovata discolor, M. purpurea, M. Lennei, M. nigra, &c. While we are in the "sub-tropical," we note a big round bed filled with Rhododendron sinense cut back two years ago and grown on in the reserve garden, with Cineraria stellata (tall), and other plants of C. aurita and C. lanata (dwarf). The taller varieties are intermixed with the Rhododendrons round about the middle of the bed, and the dwarf towards the circumference. Another bed in this part consisted of brown-coloured Wallflowers, and Tulips White Swan; and still another of Rhododendron sinense and purple Iris germanica. A mixed bed of yellow Wallflowers and scarlet Tulips was very effective. *F.*

VEGETABLES.

SEAKALE.

Seakale prefers a strong, rich ground that has been well enriched with manure and trenched to a depth of three spits. Almost any kind of manure is suitable. I find the best results are obtained from young plants, and for this purpose I annually raise a number of new "sets." These are obtained from portions of the roots of old plants, selecting the straightest portions about 6 to 8 inches in length. The shoots of the thickness of a lead pencil are to be preferred, and they may be taken from the old plants that were lifted and forced in the previous autumn. When trimming these pieces of the roots, it is well to make a straight cut across the top and an oblique one at the bottom, as by this means the proper end for inserting downwards can be readily determined. When prepared, the "thongs" or "sets," as they are termed, are tied in bundles of 100 or 50 and placed under the stage of a cool greenhouse or pit, and plunged in coal ashes. There they remain in a good condition until the following spring, when they are found to have developed a number of adventitious buds at the top. All these save the strongest should be removed, and this is best done with a sharp knife. Planting can be undertaken any time during April, provided the weather is favourable. The Seakale is a strong-growing plant, therefore it should be allowed plenty of room to develop, and not less than 2 feet between the rows, and the same distance between the individual plants is necessary. Planting should be performed with the aid of a long dibber, and as each portion of root is inserted it should be made firm. When planting is finished, it is a good practice to place a layer of ashes on each "set," as by this means slugs and other harmful insects will be kept in check. The subsequent culture consists principally of keeping weeds in check, and to see that not more than one growth develops from each crown. In the autumn, when growth is complete and the leaves have fallen, those intended for early forcing should be selected and lifted, and the smaller roots will provide the material for the next season's "sets." Those that remain in the ground may be forced where they are in the open, and a second layer of ashes should be placed over them. These crowns in the open may be forced by the aid of fermenting manure, or they may be forced and blanched under pots. In this garden we use a special Seakale-pot, that is very similar in appearance to a 4½-inch drain pipe, but with a fixed top, and by their aid we produce our finest heads of Seakale, and without the aid of any further materials.

In order to obtain the very earliest crop of this vegetable, seven crowns should be inserted in a 9-inch pot, and the soil be filled level with the top of the crowns. On this pot should be inserted another pot, bottom upwards. The "sets" should be transferred to a Mushroom or forcing house, and they will furnish a supply of the vegetable by the end of November. A succession can be maintained by potting a quantity of the crowns weekly, and introducing them into heat as described. The raising of Seakale from seed is a tedious process, but a simple one. The ground should be prepared as advised for the planting of the crowns, and the seed should be sown during April, placing two or three seeds at intervals of about 1½ feet. The strongest seedlings should be selected and the others destroyed. The ground should be kept clean of weeds, and beyond this little is required during their first season. In gardens where no convenience exists for forcing Seakale under glass, an early supply may be obtained by sowing seeds or planting the "sets" at the foot of a south wall, or some other warm aspect. When the Seakale-pot is placed over the crowns, the pot should be embedded in leaves mixed with long manure; but this latter must not be allowed to ferment too rapidly, otherwise the growths will become blackened from the excessive heat generated. Some growers produce satisfactory results by merely covering the plants with a layer of either ashes, sand, or leaf-soil, but the practice is not one to be recommended. *W. A. Cook.*

EPIGÆA REPENS.

The genus Epigæa includes a small group of plants consisting of but three or four species. The plants are found in widely different parts of the globe, E. repens being a native of the Northern United States of America, whilst another species is found in Japan. In America E. repens is known as the Mayflower, which appellation is in allusion to its season of flowering. The plant belongs to the Erica family, and, in common with members of the Ericaceæ, it should be given a rooting medium consisting chiefly of peat, and in which no lime or other calcareous material is present. The plant forms a creeping evergreen shrub, and, although it may be cultivated as a pot plant, it will thrive in a shady nook on the rock garden.

Propagation may be effected by division, but the work needs to be carefully done. Our illustration is from a plant growing in a pot in the Alpine house at Kew.

ALPINE PLANTS IN POTS.

After struggling for many years to grow some of the attractive plants from the highest Alps out of doors, I have reluctantly come to the same conclusion as Mr. Arnott (see *Gardeners' Chronicle*, May 2, p. —) as to the hopelessness of cultivating some of them in the open garden, however much care and attention we may bestow upon them. But a great deal of pleasure may be derived from growing the same plants in pots plunged in a cold frame in ashes during the sunny months, and removed to a shelf or stage of a dry, unheated, well-ventilated house when fog and damp days may be expected. But even then no mistake must be made, and there is ample scope for skill and attention.

Under certain conditions, I have found it possible to grow and to flower not only Eritrichium nanum, but also Androsace glacialis, A. helvetica, and A. imbricata. Of Eritrichium nanum I brought back five plants from the Alps last July. Of these four are flowering nicely. I may add that, in a 7-inch pot, I have four seedling plants of Eritrichium, the seed having been sown in April, 1906. These are all flowering, and I have seed pods on some of them fertilised with pollen from the partly-established plants. The seed was sown in chopped sphagnum-moss, granite chippings, silver sand, and a little peat dust. These four little plants are growing, and retain their natural habit. They are each now about as big as a half-crown piece. I have not ventured to handle them, and there seems no need to do so, as the pot is half full of drainage, and they are growing in a crust of about 4 inches in depth.

Androsace imbricata, shown in the photograph (reproduced at fig. 153), was chipped with a cold chisel out of a big boulder lying in the floor of a valley in the Valais in July, 1906, when it was about three-quarters of an inch across. I brought it home with almost no fibre to the 2 inches of tap-root, but it has never looked back and is now the picture of health.

I have also plants of Androsace glacialis, collected in 1906 and 1907. I grow them in the same way as Eritrichium nanum, planted in silver sand, granite dust, and a little peat, and surfaced round the collar with coarser granite chips. Several of my plants of both these species were potted on the mountain in their own soil, of which the above seems to be a satisfactory imitation. All the plants have done well under this treatment, and I think all have flowered—some of them profusely. A fine plant of Androsace helvetica, which I bought already established, has grown considerably since it came to me about a year ago. This species, of course, requires to be well fed in limestone, but the pot can be surfaced like the others with granite chippings.

Each pot is immersed again into a larger one, the object being to prevent damping off. The Eritrichium nanum plants are never watered directly, and the Androsaces only in spring and summer, when the air is bright and clear and there is a breeze. The outer pot is filled with silver sand for one-third of its height, and with granite chippings above that. The water given into the outer pot percolates quickly through the granite chippings, and much more slowly through the silver sand, and the silky roots of the plants have time to draw what they require, while the moisture does not hang about the collar, or near the foliage. Except when in full flower my plants are kept on the dry side, and in winter they are very seldom watered, and then only through the outer pot. But I have, in other years, lost plants of both Eritrichium and A. glacialis by keeping them over dry in the resting time. During the growing period my plants are plunged in ashes in a cold frame with ample provision for ventilation when the light is on. The bed of the frame is tilted to face the north, and the whole is placed in the sunniest and airiest possible position. In September the pots are transferred to the stage of a dry, cool house. Plenty of air and all possible sun is allowed. In very foggy weather and during a thaw I sometimes carry the Eritrichium plants across to a Carnation house, and stand them as far away from the pipes as possible and near a ventilator. I am indebted for the photograph to my friend, Mr. Digby Legard. *W. H. St. Quintin, Scampston Hall, York.*

FLORISTS' FLOWERS.

THE PICTORIAL HISTORY OF THE CHRYSANTHEMUM.

At the Chrysanthemum show held by the National Horticultural Society of France in Paris in November last, M. Georges Gibault, the librarian of the Society, formed the happy idea of exhibiting from the library of the Society a large number of books in which articles on the Chrysanthemum had appeared, together with many coloured engravings of old flowers that had been published in the various botanical and horticultural works in the possession of the Society.

My time was too much taken up with the show itself to do more than cast a very swift, albeit a very appreciative glance at the interesting collection, literary and artistic, which was staged in several glass cases. This is a precaution that is certainly necessary if any society expects the owners of rare books or prints to lend them for the purpose of public display. Fortunately M.

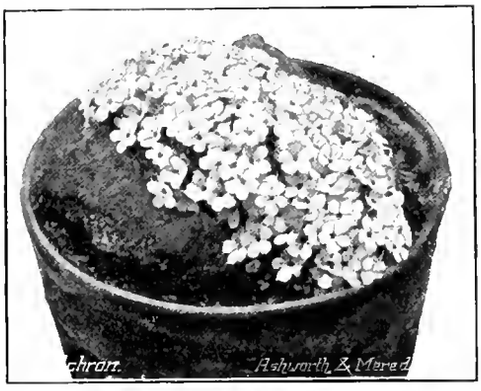

Fig. 153.—Androsace imbricata.
(The outer pot, containing sand and granite chippings, has been removed.)

Gibault gave in *Le Jardin* of December 20 a list of the principal items he staged, and, under the heading, "L'Exposition Iconographique Retrospective des Chrysanthèmes" will be found his notes, which are practically a catalogue of the principal illustrations and engravings that were shown.

It is interesting to note that the French growers and admirers of the popular autumn flower have in general a wider interest and sympathy in the literary and artistic features of their favourite than is the case with most English growers. This was made abundantly manifest to me when, after the judges' luncheon, the President of the Chrysanthemum section of the Society enquired whether I would be willing to help them by sending a few notes on the bibliography of the flower for insertion in their *Journal*. I was glad to be able to do so, with the result that the Society now possesses in its *Journal* (vide the December, 1907, number) the most complete and exhaustive bibliographical list that has ever been published on the Chrysanthemum. A small edition in independent form has been issued, and has been warmly appreciated by my French colleagues.

But to go back to M. Gibault's article in *Le Jardin*, those who see this excellent French journal will find that the list of coloured plates exhibited comprises most of the modern varieties. No history, pictorial or literary, of the Chrysanthemum can possibly be considered authentic or exhaustive unless reference be made to English authorities. The reason is that in the early days nearly the whole of the Chrysanthemums were introduced into Europe through the agency of the Horticultural Society of London, together with a few English amateurs who had become interested in the cultivation of the plant.

The first one, known as the old purple, was introduced by Blancard, of Marseilles. All the others between 1798 and 1832 were either sports or importations from China through English agencies. Some of these were introduced into France by M. Noisette, of Paris, but there is no evidence or record of further additions after the first, through French sources.

Interest having been aroused in the newcomer, our botanical magazines were not long in giving illustrations and descriptive articles concerning them, and it is just in these cases that the exhibit in Paris was the most deficient. They are of intense interest to the student of horticultural progress, for they show the immense advance that has been made in the cultivation of the flower; for it must not be considered, as many good people seem to think, that the first of the Chrysanthemums introduced was a wildling. It was certainly not that, but a cultivated flower, long grown by the Chinese florists, like most of its successors.

Sabine, whose name occupies a foremost place in the literature of our flower, did much to disseminate knowledge about the Chinese Chrysanthemum, and the plates, beautifully coloured as they are, which appeared in the *Transactions* of the Horticultural Society of London give to-day an exact idea of what the Chrysanthemums of nearly a century ago were like. But there were other books and other illustrations published in England, without which no pictorial history of the Chrysanthemum can be regarded as complete.

At this moment a more complete reference is not possible, but I think it will be serviceable to draw attention to most of those old plates that were not included in M. Gibault's article, and they are, briefly, as follow:—The purple, the changeable white, and the expanded light purple Chrysanthemums are figured in the *Botanical Magazine*. The quilled white, the superb white, the golden yellow, and the quilled pink Chrysanthemums are given in the *Botanical Register*. In Sweet's *British Flower Garden* we find excellent plates of the curled Lilac and the superb clustered yellow Chrysanthemums. The *Transactions* of the Horticultural Society of London are conspicuous for some of the best, and we there find pictures of the quilled flamed yellow, early crimson, large quilled orange, semi-double quilled pink, the quilled salmon-coloured, the semi-double quilled orange, the small yellow, the changeable pale buff, and the two-coloured Incurved Chrysanthemums.

The starry purple Chrysanthemum is figured in a very pretty plate in Morris' *Flora Conspicua*, and in the *Florists' Magazine* for 1835 we find Early Blush and Tasselled Yellow. After this period these descriptive names cease, and the present style of nomenclature came gradually into vogue. Duc de Cogliano and Minerva are figured in the *Florists' Journal* for 1843, and in many of the monthly publications, such as the *Floricultural Cabinet*, the *Floral Magazine*, *Florist and Pomologist*, &c., the Chrysanthemum in later years was freely and liberally dealt with. Unfortunately, in some instances, the figures are very indifferently executed, most of them being lithographs poorly coloured by hand. With the advent of colour printing an improvement has been made in the illustrations, but these are chiefly to be found in foreign horticultural publications.

It is very interesting to pass in review these old-time illustrations of a popular flower, and to note the gradual development and improvement of the flower all along the line. The idea has

taken root, and it is now announced that the National Horticultural Society of France will, at the next Paris Chrysanthemum Show, hold a special exhibition of literary and artistic objects. More complete particulars of the exhibition will be given later, but it is proposed that there shall be two main divisions, one to include old books, publications, prints, engravings, pictures, and old catalogues of Chrysanthemums; the other for blooms of old Chrysanthemums in cultivation prior to the year 1896. The idea is an original one, and, if properly supported, will materially help to keep up the enthusiasm of the Chrysanthemum lovers on the other side of the Channel. *C. Harman Payne.*

NOTICES OF BOOKS.

* "ORIGIN OF A LAND FLORA."

THIS is a book that will appeal rather to the botanical specialist than the public who might perhaps be attracted by its title. The author is well known for the extensive researches he has made on the structure of the vascular cryptogams, and on the problems connected with that important class of plants. The question as to how the land plants which we see around us have arisen, is closely bound up with the details of the life history of these lower forms; and our views are largely influenced by the interpretation we place on the relation existing between, for example, the prothallial generation of the Fern, and the Fern plant itself. It is generally recognised that the Ferns and their allies, as well as the Mosses, exhibit two sharply-marked phases in their life histories. The spores germinate and produce an organism on which sexual organs are produced, and from the fertilised egg springs, as a new generation, the Fern plant, or the so-called "fruit" of a Moss respectively. This germination does not give rise to sexual organs, but to spores, and from these the sexual generation once more springs. There is thus a clearly-marked alternation of the sexual and asexual phases in the life history of these plants, and many people believe that the latter has arisen as a specialised development from the fertilised egg, that the organism thus formed has reached independence (as in the Fern), and has become adapted to a terrestrial existence, whilst the sexual phase (the prothallium) remains specially fitted for aquatic conditions. According to this view, the terrestrial stage has gradually increased in importance from very small beginnings, forming, as it were, a local extension of the life history, until it has completely overshadowed the earlier aquatic parent. Professor Bower is an able exponent of this theory, which however, is far too complex to consider in detail here. It is hardly necessary to say that the book is essentially one for the advanced botanical student, and it is one that he cannot possibly neglect to study. Many of the arguments are, of course, open to criticism, and no doubt such will be forthcoming, inasmuch as there are many distinguished botanists who hold views that are quite at variance with those which are entertained by the author of this book. But the treatise itself is a masterly one of its kind, and, whatever be the ultimate fate of his theories, Professor Bower is to be congratulated on having produced a work, the permanent value of which is assured by the wealth of facts which it contains.

* *The Origin of a Land Flora*: a Theory based upon the facts of alternation, by F. O. Bower, F.R.S., Regius Professor of Botany in the University of Glasgow. London: Macmillan & Co. 1908.

[*Photograph by Chas. Jones.*

FIG. 154.—SILENE PENDULA COMPACTA, A GOOD BEDDING PLANT: FLOWERS PINK.

SILENE PENDULA.

THIS pretty pink-flowered species is a valuable subject for the flower border, where its spreading trailing branches form thick tufts which are in flower from May to August. As a border subject the plant is useful, and, in common with all the Catchflies, it will furnish a supply of flowers for the decoration of rooms, and it will associate well with the more pretentious Roses, Pæonies, Dahlias, and Carnations.

The plant, if allowed to ripen its seeds, will reproduce itself naturally by this means. A tuft of Silene pendula in flower is a pretty object on a rockery or wall garden. We remember to have seen in Paris a variety named ruberrima, with flowers more richly coloured than in the type, and it formed a very effective variety as bedded out in the Park Monceau.

Our illustration shows S. pendula compacta grown as an isolated specimen out-of-doors.

VIBURNUM CARLESII.

THIS Chinese species was shown by Sir Trevor Lawrence, Bart., at the meeting of the Royal Horticultural Society on April 14, on which occasion the Floral Committee granted the plant an Award of Merit. Although still uncommon it is in cultivation in a few gardens in this country. For the opportunity of figuring the species (fig. 155) we are indebted to our valued correspondent, Mr. W. E. Gumbleton, who sent us a flowering shoot from his gardens at Belgrove, Queenstown, Ireland, which contain so many new and rare plants. The flowers of Viburnum Carlesii when fully opened are of the purest white, and the expanded inflorescence may be likened to a glorified white Bouvardia. In addition to their beauty, the flowers are fragrant, and bunches of cut flower-sprays would form a choice subject for a vase. As a plant for embellishing a wall, this Viburnum should be especially useful. A full description of Viburnum Carlesii is given by Mr. W. Botting Hemsley in the *Journal of the Linnean Society* XXIII., p. 350.

The Week's Work.

FRUITS UNDER GLASS.

By T. COUMBER, Gardener to LORD LLANGATTOCK, The Hendre, Monmouthshire.

Queen Pineapples.—Plants on which the fruits are now swelling should have their roots watered once each week with tepid water containing a small quantity of Peruvian Guano. They need an atmospheric temperature at night of 70°, but a few degrees higher in mild weather will be better. Carefully ventilate the house early on bright days, gradually increasing the ventilation as the day advances, and close the house again in the afternoon at such a time that the temperature will rise to 90° for a short time. Maintain a moist atmosphere by lightly spraying the plants overhead, damping between the pots early in the morning and again at closing time during fine weather, and the paths also as often as may be required. Only one or two suckers, which may be required for propagation, should be allowed to remain on the plant; the remaining ones should be removed as soon as they are seen. Afford a little shade during the hottest hours of the day (by the use of thin tiffany blinds) to prevent the fruits or leaves from becoming scalded owing to the direct rays of the sun shining upon them whilst their surfaces are wet. When the fruits commence to ripen, watering must be discontinued; the atmosphere should be drier, and the ventilators may be left partially open at night. If too many fruits appear to be ripening at one and the same time, some of them may be retarded by placing the plants, as soon as the fruits commence to colour, in a moderately cool house or pit. Those plants that were potted into their final pots in February will require more liberal supplies of water now that their roots are becoming numerous, and a little guano may be mixed in the water. On no account, however, must the watering be excessive, it being better to err in the opposite direction. If the roots suffer from drought, the effect of this will be seen by the edges of the leaves becoming unduly contracted (cupped). Keep these plants entirely free from suckers. Ventilate the house, afford shade to the plants and promote atmospheric moisture, as directed, for the plants now swelling their fruits.

Smooth Cayennes and other varieties.—Plants of varieties of Pineapple which are expected to provide ripe fruits during next winter should be almost fully developed specimens by this date, and their pots should be well filled with active roots. Attend carefully to the routine management and maintain a bottom heat of about 85°. By midsummer the plants should

complete their growth and commence to develop their fruits. If necessary, this stage should be encouraged by keeping a drier atmosphere and somewhat restricting the supply of water to the roots, avoiding carrying this treatment to excess. The plants of winter-fruiting varieties that have been raised from suckers potted into 7-inch pots early in spring are now sufficiently well rooted to be shifted into well-drained pots 12 inches in diameter. Use a compost of light, fibrous loam (rejecting the fine particles), and mix with it a little bone meal and soot. Pull away a few of the bottom leaves from each plant, remove the crocks from the soil, and in repotting ram the compost firmly down around the old soil. Plunge the pots up to their rims in a bed having a heat of 85°, and let the atmospheric temperature be maintained at 70° at night, allowing it to rise 5° or 10° by day. Keep the atmosphere rather close and in a moist condition for a week or ten days following the operation, and spray the plants overhead each morning and afternoon. Provide shade from bright sunshine, bearing in mind that the Smooth Cayenne suffers injury more readily than any other variety if exposed to direct sunshine. The greatest care should be taken to avoid over watering freshly-potted plants, and equal diligence is necessary to see that the soil is not allowed to become too dry. Every care should be taken of the leaves during the operations of potting and plunging the plants, but it is not wise to tie the leaves of each plant into a bundle.

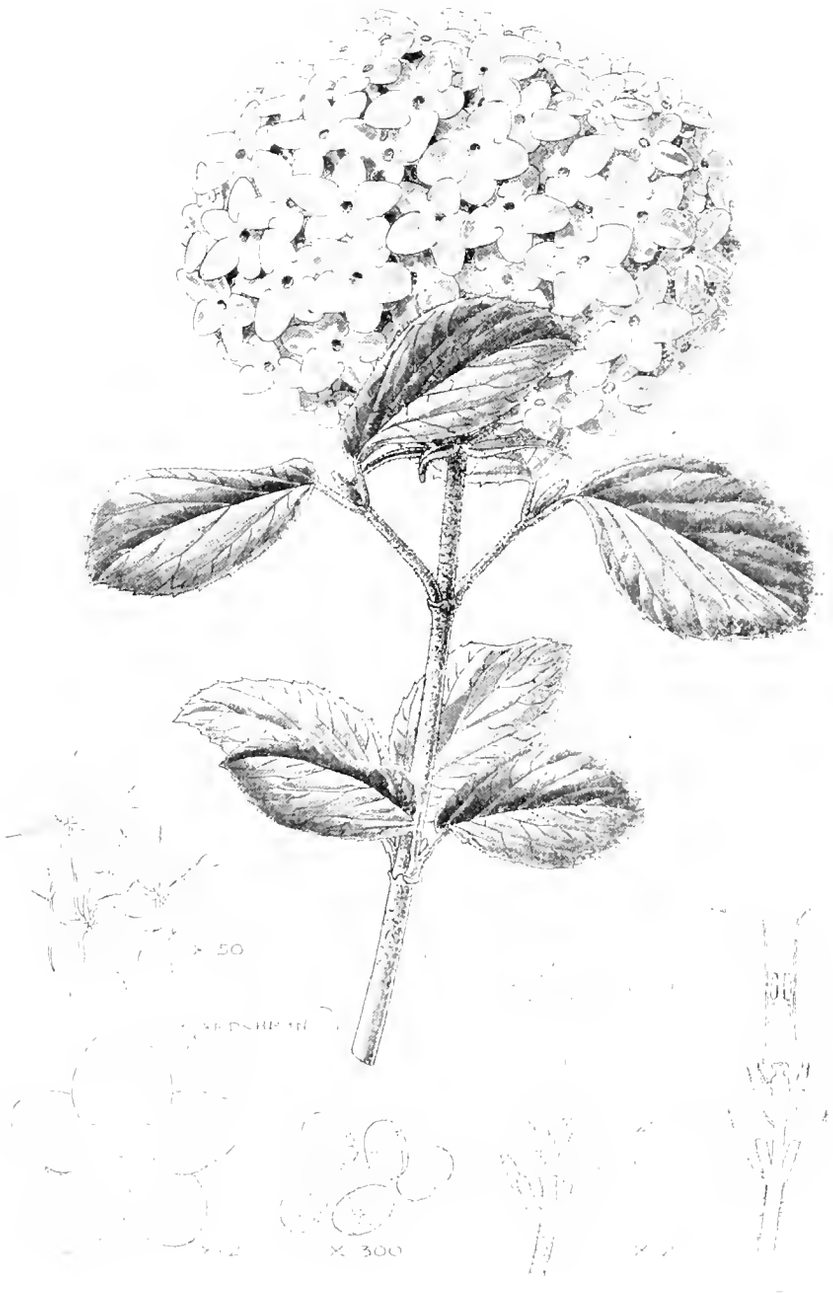

Fig. 155.—Viburnum carlesii: flowers white.
(For text see p. 345.)

THE ORCHID HOUSES.

By H. G. Alexander, Orchid Grower to Major G. L. Holford, C.V.O., C.I.E., Westonbirt, Gloucestershire.

Dendrobiums.—The evergreen species and varieties which flower at about this season are beautiful and attractive plants. D. densiflorum, D. Farmeri, D. thyrsiflorum, D. moschatum, D. Dalhousianum, D. fimbriatum, D. chrysotoxum, and D. suavissimum are free-growing plants that can be accommodated in an ordinary plant stove while making their growths during the summer months, and in the winter rested in a warm greenhouse. These plants usually commence developing their new growths and flower-spikes simultaneously, and by the time the flowers are past these young growths are somewhat advanced in making roots from the base. At this stage any necessary repotting or surfacing should be attended to. The dwarf-habited kinds should be placed in baskets and these suspended from the rafters; whilst the taller-growing ones are best cultivated in pots and placed on the stage. Avoid using receptacles of larger sizes than necessary, and in selecting them be careful that they are clean and sufficiently provided with drainage material. The plants, when well established, should be kept close up to the light, using a moderate degree of shade only to protect them from bright sunshine, syringing the foliage frequently during bright weather.

D. Phalænopsis Schröderiana.—With the warmer weather and greater amount of sunlight, this splendid species is pushing forth new growths rapidly. The plants are best cultivated in receptacles that can be suspended from the rafters in the warmest division. Very little shade being necessary, the thinnest of materials only should be employed, and this only during the hottest part of the day in summer. Any of these plants that need fresh rooting material should be given attention when the new growths have attained a height of 3 inches, for new roots will then emerge from the base of the pseudo-bulbs and quickly establish themselves in the compost. Well-drained pans should be selected for the plants, and when repotting these latter, remember that the best results are obtained from plants that have their rooting-space confined. When in full growth and the pseudo-bulbs are in course of formation, the plants should be examined each day for watering, a plentiful supply of moisture at the roots being necessary. The atmosphere should also be maintained very moist, and the syringe may be used freely amongst the plants on bright days.

D. formosum, D. infundibulum, and its variety Jamesianum.—D. formosum is a very useful Orchid where there is a great demand for the choicest white flowers in autumn. The plants, which are now commencing to grow, should be treated as I have advised for D. Phalænopsis. D. infundibulum is also growing and making new roots, and may be repotted or top-dressed according to the requirements of each plant. Their treatment is much the same as D. formosum, except that this species should be cultivated in a cool intermediate temperature instead of in the warmest division.

Potting compost.—For all the species I have mentioned a similar compost should be employed to that recommended in a previous Calendar for Dendrobiums. Exercise the usual care in watering all freshly-potted plants, and afford them extra shade on bright days, especially to those specimens which have had all the old materials shaken from their roots.

THE KITCHEN GARDEN.

By E. Beckett, Gardener to the Hon. Vicary Gibbs, Aldenham House, Elstree, Hertfordshire.

The season.—The welcome change in the weather a fortnight ago has done much to promote the growth of vegetation, and if we get no further spring frosts early vegetables, though somewhat late, are likely to be abundant and of good quality. Clear the ground of the remains of any vegetable crop as fast as these cease to be of further use. Nothing tends to impoverish the ground more than Cabbages or other species of Brassica, when they commence to flower.

Cucumbers.—Plants in full bearing, whether cultivated in houses, pits, or frames, will need to have the oldest of the growths thinned out and the new growths regulated and tied in. Rigidly avoid overcropping the plants, but apply abundance of water to the roots as well as liquid manure. If liquid manure is difficult to obtain, there are many forms of patent manure which are of very great value to this crop. In order to prevent attacks of black aphis, one or two fumigations with the XL-All vaporiser should be carried out. Apply a surface dressing of good loam and half-decayed horse manure, in equal parts, at intervals of about ten days. Employ a little ventilation early in the morning, but close the lights again early in the afternoon. Should any of the plants show serious signs of exhaustion, it will be wise at this season of the year to throw them out and start again with young plants and fresh material.

Tomatos.—Plants which have been well hardened and properly prepared for planting out of doors, may now be safely put out into sheltered positions. I have previously stated that it is almost useless to cultivate Tomatos in the open garden unless seed is sown early in the season,

so that at the end of May strong plants may be ready which will commence to fruit almost immediately after they are planted out. Wherever it is possible to do so, let the plants be put against a wall or building facing to the south. The soil should not be manured at the time of planting, and no stimulant will be required until a considerable number of fruits have set. Cut away all side growths, keeping each plant to one main stem. Make another sowing for raising plants to fruit under glass during autumn.

Asparagus.—Plants in the seed bed should be thinned out to distances of 4 to 6 inches apart, and the surface of the ground should be kept frequently stirred. Seeds may still be sown, if by any chance the operation has been neglected, or seeds have failed to germinate. The permanent beds should be examined each day, and the thickest shoots cut for use carefully with an Asparagus knife when they are about 3 inches in height. Hand-weed the beds to keep them perfectly clean.

Maize or Indian Corn.—In warm districts, and during favourable summers, Indian Corn may be induced to sufficiently develop their Cobs for consumption if the plants are raised under glass in boxes and planted out in a southern aspect in well-prepared ground. There are several improved varieties procurable.

PLANTS UNDER GLASS.

By Thomas Lunt, Gardener to A. Stirling, Esq., Keir, Perthshire, N.B.

Chrysanthemums.—Plants which are being cultivated for producing large blooms should now be repotted for the last time. Before commencing this operation, select a sufficient number of each variety, being careful not to retain more than can be properly accommodated in the houses in September, it being much better to cultivate a moderate number well than that a larger number should be more or less spoiled by overcrowding. Examine carefully for green fly, and if any of this pest be detected, let each plant be dipped in quassia water. The most suitable-sized pots for most varieties are those having a diameter of 10 inches. Use clean pots and provide each with ample means of drainage, as Chrysanthemums need an abundance of water during the summer months, but are not capable of thriving in a water-logged soil. Let the compost consist of rather heavy loam, leaf-mould and rough sand, as the roots will now require a soil rather richer and heavier than that which was used in the 6-inch pots. Immediately after potting provide each plant with a small stake in order that it may be kept firm at the neck. Cultivators in Scotland should place their plants in a position where it will be possible to afford them protection from frost; it is scarcely safe to expose them fully until the end of the first week in June. For their accommodation during summer, it is desirable to arrange the plants upon a square piece of ground which is covered with ashes. Place 7-feet high posts at distances of 15 feet apart, and in lines separated from each other by 6 feet. A strong fencing wire may then be stretched along the lines from post to post, and the stakes of each plant being tied to this wire, they will then be safe from injuries which would otherwise be caused by winds. Each one will eventually need two stakes, one placed on either side of the pot. The stakes should be tied across the top with a piece of string the same distance apart as at the base. When placing the plants in their summer position, it is essential that each should be given sufficient space that the shoots and leaves will be fully exposed to sunlight. When tying the shoots to the stakes, always make the ties upon firm wood, allowing the soft, unripened tops to sway under the influence of the wind. Suitable stakes are the red-wood stakes 5 feet long, and they are the cheapest in the end. These may be fixed firmly in the soil, whereas the smoother surfaced Bamboo stakes are apt to become loosened. A piece of crock about 3 or 4 inches square should be placed on the surface of the soil in each pot, and when applying water it should be poured on to this material. By its use watering can be carried out more quickly, and the surface soil will not be washed out of place. Planks 9 inches wide are useful for standing the pots upon whilst the plants are out of doors.

THE FLOWER GARDEN.

By W. Fyfe, Gardener to Lady Wantage, Lockinge Park, Berkshire.

Summer bedding.—Lobelia cardinalis and its varieties are amongst the most ornamental of bedding plants, and their value should not be overlooked. Under good cultivation the plants attain a height of about 3 feet, and if grouped together in beds formed on the grass, or by the margin of streams, they have a very fine effect. Useful plants for forming a groundwork for these Lobelias include Alyssum maritimum, Gazania splendens, and G. s. variegata, Dactylis glomerata, any of the dwarf Ageratums (such as Countess of Stair, and Veronica Andersoni. If these plants be used the Lobelias need not be planted so closely together.

Lantanas.—These plants are very free-flowering, and exhibit various colours, including shades of pink, white, lilac, crimson, yellow and rich orange. They are very handsome if trained as standards, and the practice of planting dwarf Lantanas to form a groundwork, and interspersing standards of a distinct colour is commendable.

Coleus Verschaffeltii is still the best Coleus for bedding out-of-doors. It is very effective if grouped alone, or if interspersed with standard plants of the white Marguerite.

Heliotropium and Calceolaria amplexicaulis.—Standard plants of these species have a very good effect over beds of herbaceous Pæonies, and they cause the beds to remain attractive for a longer period.

Miscellaneous groupings.—It is scarcely necessary to mention that beds planted with Madame Crousse Pelargonium, with a few standard plants of the same variety amongst them, are exceedingly attractive. The standard plants should be about 5 feet in height. Dwarf varieties of Ageratum, with plants of Abutilon striatum interspersed; Raby Castle Carnation, mixed with named varieties of Gladiolus and Montbretias; Celosias associated with Fuchsias; bronze and yellow-flowered Begonias mixed with standard plants of Streptosolen Jamesonii, are all pleasant associations.

THE HARDY FRUIT GARDEN.

By E. Jordan, Gardener to The Dowager Lady Newburgh-holme, Warter Priory, Yorkshire.

Cherries.—Kentish, May Duke, and other early varieties will now have set their fruit in most districts, therefore examine the trees carefully for black aphis and maggots. The aphis may be destroyed by syringing the trees with Quassia Extract or some other insecticide, but the maggots are hidden away in the curled leaves, and these leaves should be taken from the trees by hand, and burned. Trees of the variety Morella must be kept clean from aphides at all costs, or they will badly cripple the points of the shoots. If the attack of aphis is slight it is usually sufficient to dip the points of the shoots in weak tobacco water, and apply a syringing with clear water on the morning following that operation. Disbud any trees that are well furnished with shoots, removing back and foreright shoots, or any others that will not be required permanently for the trees (see also the "Calendar" published in the issue for April 25). Do not stop the leading shoots, or thin the fruits at the present, as it is probable that many of them will fall from the trees during the process of stoning.

Mulching.—This important operation in hardy fruit culture is practised for the purposes of conserving the moisture in the soil, applying plant food to the soil, and economising labour. Mulching upon heavy soil should be deferred until the ground has become warmed by the summer sun, except in cases of freshly-planted trees, which should be mulched with light litter only. Trees which are not bearing crops do not require dressings of rich manure, and its application might do harm by encouraging the trees to make gross and unfruitful growth. It is better to apply a good dressing of wood ashes or burnt refuse, covering this material with a little stable litter. Established trees, however, which are growing on light soils, and any which have been worked upon surface-rooting stocks and that have carried crops of fruit, require rich stimulants. These should be afforded a liberal dressing of stable manure, followed by a copious watering, repeating the mulch later in the season; this is better than making an excessively heavy application at one time. On all occasions, before applying the mulch, or before watering the ground, let the surface soil be slightly pricked up by means of a fork. Wall-trees growing in moderately deep and well-drained borders, and having their roots near to the surface, will not succeed perfectly unless they are given rich mulchings and liberal waterings.

General work.—Continue to use the hoe over the surface of the ground amongst hardy fruit trees, and do not neglect any of the little details that are necessary during this busy season to enable the trees the better to develop their crops.

PUBLIC PARKS AND GARDENS.

By James Whitton, Superintendent of the Parks and Open Spaces in the City of Glasgow.

Culture of hardy plants.—Amongst the many phases of present-day gardening, one of the most pleasing is the cultivation of hardy plants. I use this term "hardy plants" in its fullest sense, including in it all species that are capable of withstanding ordinary winters in this country. Formerly a large number of plants which had long been in cultivation in this country were either totally neglected or relegated to that plant purgatory, the back border. I will not discuss the causes which led to the former neglect or present appreciation of these plants; but, in welcoming the change which has saved many valuable subjects from oblivion, offer some observations on their value for the decoration of public parks. Before doing so, let me remark that it is necessary to keep always in mind the fact that the use of scarce plants in public gardening is not to be recommended unless under special circumstances. There is such a wealth of material nowadays at our disposal that there is no justification for extravagant expenditure of public money on plants which are costly because they are scarce.

Question of arrangement.—In some cases it appears to be the aim of the cultivator to dispose his plants in solitary isolation that each may exhibit its individual characteristics, but without regard to the creation of pleasing effects, whether by harmony of colour or contrast of form. While this method may be permissible in certain situations where arrangements that tend to the easy and convenient comparison of species is almost a necessity, it cannot by any stretch of the imagination be looked upon as artistic gardening. Though my own personal taste is in favour of the free and natural style, I am bound to admit that, in particular situations, the formal garden possesses features of beauty and grandeur peculiarly appropriate to its surroundings. In so far as this formalism applies to public gardens, it may be observed that the style is not only more costly to adopt, but also to maintain. Returning to a consideration of the value of hardy plants for park purposes, I will first speak of their use for naturalising in suitable situations. In how many instances are spring-flowering bulbs planted as freely as they might be? We see the annual displays made in beds of formal outline; but this is not what is meant. I want to emphasise the better plan of using them more freely in a natural manner in the wooded and more grassy parts, where they will afford a special interest to visitors, who watch with the keenest interest for the first appearance in spring of the Snowdrop and the Winter Aconite. Unfortunately, these two plants are not always a success in town gardens. They appear to be somewhat fastidious as to soil, and they dislike town smoke just as do the Hybrid Perpetual Roses. Where they are capable of thriving, and are planted in wide, irregular masses, they are appreciated as much as their more showy successor, the Crocus, which plant, being less fastidious, will often succeed where Snowdrops fail. The brilliant effects obtained by planting Crocuses in masses has been frequently described and illustrated in the *Gardeners' Chronicle*; but, despite these excellent object-lessons, they are often still planted in stiff lines and formal designs. In considering the Crocus, one has to remember the injury caused to the flowers by the house sparrow so common in urban districts. The birds appear now to be worse even than formerly, for, whereas they used to confine their attention to the yellow varieties, they now destroy the flowers irrespective of colour. Fortunately, however, the town Crocus is not so liable to injury from the short-tailed mouse as are the same plants when grown in the country.

(To be continued.)

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden W.C.

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Appointments for June.

TUESDAY, JUNE 2—Nat. Amateur Gard. Assoc. meet.

THURSDAY, JUNE 4—Linnean Soc. meet.

SATURDAY, JUNE 6—
Soc. Franç. d'Hort. de Londres meet. German Gard. Soc. meet.

MONDAY, JUNE 8—
Bank Holiday. Harpenden Fanciers and Agric. Soc. Sh. United Hort. Ben. & Prov. Soc. Com. meet.

TUESDAY, JUNE 9—
Roy. Hort. Soc. Coms. meet. British Gard. Assoc. Ex. Council meet. Nat. Rose Soc. Com. meet.

THURSDAY, JUNE 11—
Exhibition of Colonial Fruits in the Roy. Hort. Hall, Westminster (2 days).

WEDNESDAY, JUNE 17—
Roy. Bot. Soc. Summer Exh. (3 days). Yorkshire Gala, York, Jubilee Exh. (3 days).

THURSDAY, JUNE 18—Linnean Soc. meet.

SATURDAY, JUNE 20—German Gard. Soc. meet.

TUESDAY, JUNE 23—
Roy. Hort. Soc. Coms. meet. Oxford Fl. Sh.

WEDNESDAY, JUNE 24—
Richmond Fl. Sh. Hort. Sh. at the Franco-British Exhibition, Shepherd's Bush (3 days).

THURSDAY, JUNE 25—
Isle of Wight Rose Sh. at Ryde (provisional).

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—55·9°.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, May 27* (6 P.M.): Max. 75° Min. 55°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, May 28* (10 A.M.): Bar. 30·4; Temp. 70°; *Weather*—Bright sunshine.
PROVINCES.—*Wednesday, May 27* (6 P.M.): Max. 70° Guildford; Min. 57° Ireland N.W.

SALES FOR THE ENSUING WEEK.

WEDNESDAY—
Bedding Plants, Bulbs, Palms, &c., at 12; Lycoris, Nerines, &c., from Japan, also Palm seeds, at 3, by Protheroe & Morris, at 67 & 68, Cheapside, E.C.

FRIDAY—
Imported and Established Orchids, by Protheroe & Morris, at 67 & 68, Cheapside, E.C., at 12.45.

The Temple.

The institution of the Temple Show may be said to have come of age in the present week, for the exhibition that is still open as these pages go to press is the twenty-first that has been held by the Royal Horticultural Society in the historic grounds of the Inner Temple. The history of these shows has been characterised by an extraordinary degree of success, insomuch that their popularity has continued to grow until, at the present time, the very difficulties and inconveniences that attend them are attributable to the unparalleled attraction they present to the Fellows and general public. At the termination of such a considerable period the Society may well receive congratulations upon this satisfactory feature in its yearly calendar, and we may express the hope that no circumstances may arise to interrupt the favourable arrangement that exists between the Society and the Benchers.

Although it would be unwise to argue that the holding of exhibitions is the highest or most important work to which an influential society can direct its energies, it is none the less true that properly organised shows have a real value that is very generally appreciated, and the Temple exhibitions would still be necessary if they became a small tax on the Society's finance, a circumstance which makes it the more apparent that it is a matter for congratulation that they are not only self-supporting, but are a means of augmenting the funds.

It is entirely due to the restricted space available in these gardens that the inconvenience of overcrowding is felt so keenly as is the case at the present time, and on this occasion the Council has certainly shown a desire to serve the convenience of the Fellows as far as possible. With this object the price of admission was raised on the opening day from seven and sixpence to ten shillings, but so far as we could judge the number of persons present on Tuesday afternoon was as great as in former years! A greater boon to the Fellows was the regulation which excluded the general public from the exhibition altogether on the Wednesday morning until 12 o'clock noon, for this concession afforded the Fellows an opportunity to see the exhibits in some degree of comfort, which was quite impossible on

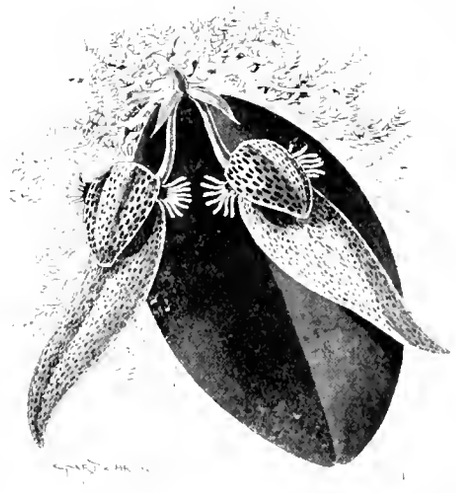

FIG 156.—BULBOPHYLLUM MIRUM, AN INTERESTING SPECIES EXHIBITED AT THE TEMPLE SHOW. (See p. 253.)

the Tuesday after the tents had been thrown open. The manner in which the Fellows have shown their appreciation of the facilities provided on Wednesday will no doubt induce the Council to make this arrangement a permanent one.

In several directions further efforts were made to relieve the congestion, and the alterations were certainly improvements. There have been frequent complaints in former years that the long narrow tent extending from the entrance gates became so thronged with people that a very considerable time was necessary to get from one end to the other, and in hot weather the atmosphere was so oppressive that ladies especially suffered considerable inconvenience and fatigue. By making an opening in this tent at the point opposite to the secretary's tent an opportunity was afforded to get out into the open air at half the distance, and this opening was also of great value for the admittance of air. The alteration in one of the other tents was of lesser importance, but its effect was in the same direction, whilst the battened way over the grass from the main entrance on the Benchers, or Fleet Street, side of the gardens allowed visitors to pass to the tents and return therefrom in a shorter space of time.

Of the event itself, it must be said that the display is very like former Temple shows. These exhibitions show but little variation from year to year, and, as we have remarked on several former occasions, it would be satisfactory if means could be devised that would introduce some new features. Having so recently witnessed the great exhibition at Ghent, in Belgium, some of those present at the Temple could not refrain from contrasting the methods adopted at Ghent for displaying the exhibits and the lack of method observable at our own shows. It is admitted that the enforced limitations of space at the Temple offer a serious hindrance to the adoption of any intelligent scheme for producing the best scenic effects, but that this is not the only reason for the neglect is proved by the Holland Park exhibitions, for at Holland Park there is an abundant space available, yet the methods of staging are usually little better than at the Temple. It may be stated here that the exhibits of Messrs. Cutbush, both in the tents and out-of-doors, have been arranged with more regard to effect than most others. The groups of Carnations in the Orchid marquee over a bright pink groundwork of Polyantha Roses may serve as an example, though perhaps the general tone of pink and rose colours was a little marred by the inclusion, in one corner, of a plant of Carnation with flowers of an orange shade not perfectly harmonious with the rest.

Apart from this question of arrangement there is little room for criticising the Temple shows. They are the means of bringing together a large number of exhibits which represent the very best cultivation practised in this country, and the general display just as perfectly illustrates general gardening in Britain as the Ghent show depicted the commercial horticulture of Belgium. It would not be easy to conceive a greater contrast than is presented by the two shows. In the one case the display consisted of an enormous number of splendid specimens of stove and greenhouse plants, with whole plantations of Rhododendrons, but with scarcely any hardy flowering plants represented, whilst one of the most striking features of the Temple Show lies in the enormous number of hardy flowers, thus testifying to the increased appreciation they now receive in this country. There were very choice Orchids at Ghent, but they were fewer in number than those staged at the Temple. But why attempt to compare the exhibitions? They are so essentially different that a visit to one but helps us to appreciate more highly the other!

We have said that the Temple shows illustrate in a satisfactory manner the gardening practised in this country, but this statement requires qualification on the present occasion for the reason that fruits and vegetables were less numerously shown than usual, and there was not a single exhibit of this nature from an amateur's garden. It is, of course, true that the date of these shows is very early for such produce, but on previous occasions

some satisfactory collections have been staged, and it would be a pity if these are to be discontinued, if only for the reason that foreign visitors will be led to think that the culture of fruits and vegetables is not given proper attention here, which would be quite contrary to the facts.

The present exhibition is not likely to be remembered for any outstanding novelty it revealed. Amongst Orchids the Odontiodas are now becoming familiar plants, and although the new ones shown by Messrs. Charlesworth and Mons. Henri Graire are interesting, they can hardly be expected to cause the same amount of excitement that was produced in 1904, when the first product of this bigeneric cross was exhibited by Mons. Vuylsteke. The Lælio-Cattleya Elva, Westonbirt variety, from Major Holford is a very showy flower, and the Cattleya Mendelii "His Majesty," shown by Mr. Francis Wellesley, also the blotched Odontoglossums from M. Vuylsteke, not to mention other new Orchids, which are described in our report, all afford matters of interest to Orchid cultivators, whilst the curiously-formed Bulbophyllum from Sir Jeremiah Colman, Bart., shown at fig. 150, has a botanical interest that is unapproached by many of the more showy species. Whilst referring to the Orchids it may be mentioned that the Veitchian Cup has been awarded to Mr. F. Menteith Ogilvie, and that Major Holford, so far from having exhausted his resources by his recent exhibit in Belgium, has a magnificent show of well-cultivated plants, some of which we illustrate in this issue.

Apart from the Orchids, some of the best novelties are the stove species exhibited by Messrs. Sander at Ghent and already illustrated in these pages, but a number of awards were granted to hardier plants which are described on another page.

On the opening day the exhibition was graced by the presence of H.M. The Queen and H.R.H. Princess Victoria.

It is interesting to note that the show includes contributions from one hundred and twenty-five exhibitors, including several from Belgium and France, a much larger number than was the case some years ago, when the area covered by the exhibits was equal to that available at the present time.

Our Supplementary Illustration represents a view of the roof garden at Cardiff Castle, a somewhat unique feature of the building. We understand that the creation of this garden was the idea of the late Marquis of Bute, whose tastes were pre-eminently antiquarian, and who loved to surround himself as much as possible with such things as were reminiscent of other ages. The roof garden—colloquially called the "Peristyle"—is situated at the top of an octagon tower about 100 feet from the ground level, and from windows on its four sides extensive views are to be obtained of the whole of the City of Cardiff and the surrounding country side. From the floor—which is mosaic—to the very tiles of the roof no expense has been spared in its construction, and its artistic embellishments are the wonder and admiration of all visitors. The fountain in the centre is constructed of bronze, and the animals represented are beavers—the top one full grown and the four lower ones its young. In the background is seen a large bronze statue of the Madonna and Child, the pedestal of which is a slab of white marble resting upon a base of polished Aberdeen granite. The beautiful paintings on the upper portion of the walls depict scenes from the life of the prophet Elijah, and the explanation of each picture is given in Hebrew characters below. Frescoes representing animal subjects occupy the lower portions of the walls. Needless to say, this is not an ideal roof garden from the plant grower's point of view, as it is too much shut in and shaded. Its beauty and interest depend solely on Art and not on Nature; and it is, after all, only a garden in name.

Kew Guild Dinner.—This annual festivity was celebrated at the Holborn Restaurant on the 25th inst., when 86 members of the Guild assembled. Prior to the dinner, the annual meeting was held, and the report of the year presented. Mr. Bean retires from the editorship of the *Journal*, and in future the Committee will edit the work. The demand for the *Journal* was larger in 1907 than in any previous year, 726 copies having been distributed. The total number of life members is now 254. The dinner was presided over by Mr. W. W. Pettigrew, superintendent of the Cardiff Public Parks, supported on the right hand by Dr. Otto Staff, and on the left by Mr. A. W. Hill, M.A., Assistant Director of the Royal Gardens, Kew. The chairman, in proposing the toast of the Kew Guild, said that such an institution was the means of binding the members together in friendship. Friends, and especially those made when young, are the most valuable possessions one can have. Kew, he said, afforded especial opportunities for forming friendships, and he urged the young men at present in the gardens to select their friends carefully, but with this reservation, make as many friends as they could. An institution such as the Kew Guild possessed great possibilities. Its members include some of the foremost horticulturists of the day, and these were scattered all over the world. It had power, if used aright, to influence the public and the Government to the benefit of gardening generally. He would like to see some recognised horticultural degree, and he thought that the Government, through Kew, might lead the way in this matter. He urged the young gardeners at present at Kew to embrace all the opportunities the gardens afforded them in learning both the practical and scientific sides of their profession. Mr. Daydon Jackson, in the absence of Mr. W. Botting Hemsley, F.R.S., responding, said that the faculty of cultivating friendships was a valuable one; old friends are the best, but unfortunately one is always losing them. Mr. Watson referred to the approaching retirement of Mr. Hemsley from his duties at Kew, and spoke in sympathetic terms of the indisposition of Mr. Geo. Nicholson, a vice-president of the Guild. Mr. R. Hooper Pearson proposed the toast of "The Chairman." He said that Mr. Pettigrew's work at Cardiff was of a character deserving the highest praise, and as an employer of young gardeners his conduct towards them was exemplary. Not only did Mr. Pettigrew take an interest in teaching them the practice, but also the science of their calling. At the same time he was a good disciplinarian, and enforced such habits as punctuality, which were in themselves of value to young men. Mr. Pearson referring to the chairman's speech, declared

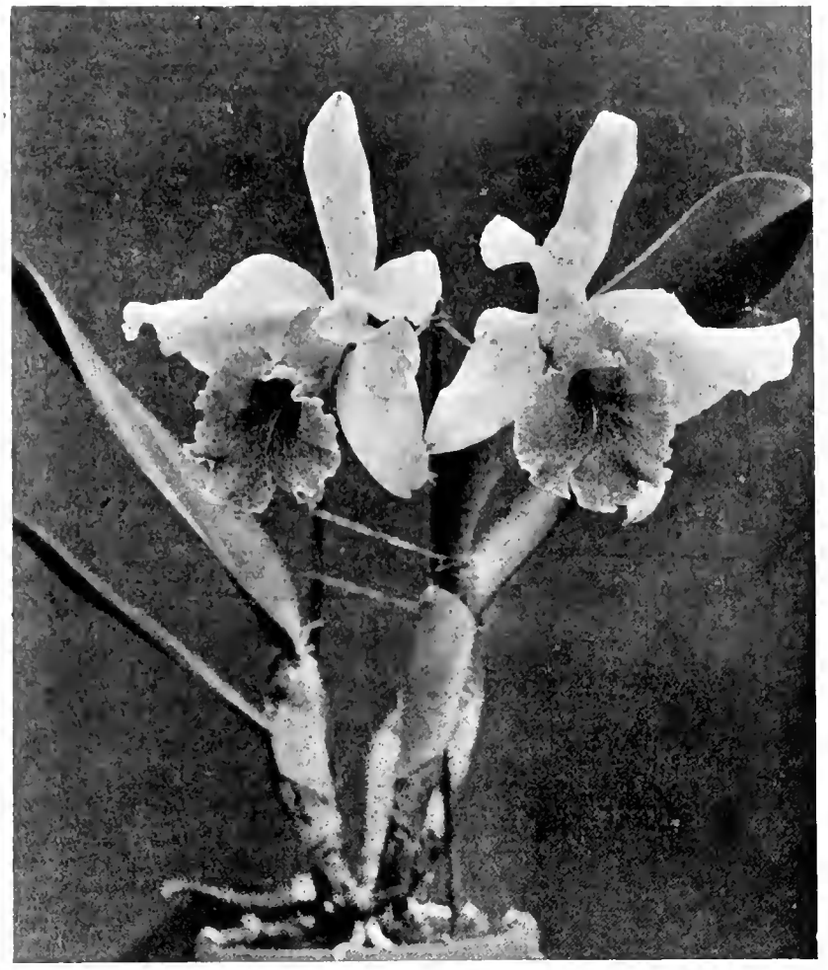

Fig. 157.—Lælio-cattleya "Elva," Westonbirt variety. Awarded a First-class Certificate at the Temple Show.

that it was an argument in favour of horticulture receiving State recognition, which was desirable from every point of view, and a matter that should engage the earnest attention of gardeners. The chairman responded, and shortly afterwards the meeting terminated.

FLOWERS IN SEASON.—We have received from Mr. W. BAYLOR HARTLAND a box of Tulips from his noted Irish nursery at Ard-Cairn, Ballintemple. Among the many beautiful varieties sent were Orange Globe, a variety having long petals of scarlet colour flushed with cerise and edged with orange; Mrs. Moon, one of the best of the yellow Tulips; Rosalind, of a pleasing shade of red, of good form, and not over large; Pompadour, a big, bold scarlet flower; Shandon Bells, with white ground splashed with pink; and Stella, of bright rose colour, with a white base.

M. ABEL CHATENAY.—English visitors to the Paris Salon, who are personally acquainted with M. ABEL CHATENAY, the genial secretary of the National Horticultural Society of France, will have no difficulty in recognising the large three-quarter length portrait as an excellent and life-like representation of this gentleman. The number is 864, the artist M. LEON ARMAND HUET, and although the title given is merely M. A. C. in the catalogue, those who know M. CHATENAY need no further information. It may be mentioned that in this year's Salon there are nearly 100 pictures of fruit and flowers in oil or water-colour, so that horticultural visitors to the Salon may be sure of an hour's interest outside that afforded by the ordinary exhibits.

FIG. 158.—SOME CHOICE VARIETIES OF HIPPEASTRUM, EXHIBITED BY MESSRS. KER AND SONS AT THE TEMPLE SHOW.

MR. THEODOR REIMERS, at Neumuhlen, near Hamburg, writes a correspondent, will celebrate his 50 years jubilee as superintendent of the well-known garden of HERR ETATSRATH DONNER on June 8 next. The garden was originally a very small one, but owing to Mr. REIMERS' work it is now one of the most celebrated and interesting in Germany. It is visited by a great many gardeners who have reason to go to Hamburg. Mr. REIMERS is well known to many of our readers.

LINNEAN SOCIETY.—The two new foreign members of the Linnean Society are Professor OTTO BUTSCHLI, well known for his remarkable investigations on the lower animals and on the structure of protoplasm, and Professor A. G. NATHORST, the distinguished Swedish palæontologist.

——— A meeting will be held on June 4, at 8 p.m., when the following papers will be read:—1, Prof. A. DENDY, F.R.S., "Note on the Spicules of Chirodota gemmifera, Dendy and Hindle"; 2, Mr. E. S. SALMON, F.L.S., "Two new Fungus Diseases"; 3, Mr. F. N. WILLIAMS, F.L.S., "The Caryophyllaceæ of Tibet"; 4, Mr. F. A. POTTS, "Polychaeta of the Indian Ocean"; 5, Dr. S. J. HICKSON, F.R.S., and Miss HELEN M. ENGLAND, M.Sc., "The Stylasteria of the Indian Ocean"; 6, Messrs. W. N. CHEESMAN, F.L.S., and T. GIBBS, "A Contribution to the Mycology of South Africa."

GARDENERS' ROYAL BENEVOLENT INSTITUTION.—Sir FRANK CRISP, LL.B., J.P., has forwarded the sum of £31 6s. 5d. in aid of the funds of the above institution, being a proportion of the proceeds of admission fees received for opening Friar Park, Henley-on-Thames, to visitors.

MR. W. HONESS who contributed the Weekly Calendar on "The Kitchen Garden" for these pages last year, has removed from Cobham Park Gardens to take up the position of gardener to WALTER RAPHAEL, Esq., Hopedene, near Dorking, Surrey. The new garden contains some excellent glass houses which afford good facilities for indoor fruit and plant cultivation.

RHODODENDRON EXHIBITION.—Messrs. JOHN WATERER & SONS, LTD., Bagshot, inform us that their annual exhibition of Rhododendrons in the Royal Botanic Society's Gardens, Regent's Park, will be opened on Wednesday, June 10, and remain on view throughout the month. Judged by former displays this exhibition is likely to be worth a visit by all those interested in garden Rhododendrons.

APPOINTMENTS ABROAD.—We learn that Mr ROBERT FYFFE and Mr. FRANK REGINALD LONG both members of the gardening staff at Kew, have been respectively appointed, on the recommendation of Kew, by the Secretary of State for the Colonies to the post of Superintendent of the Botanic, Forestry, and Scientific Department of the Uganda Protectorate, and Superintendent of the Government Plantations in the Federated Malay States.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

EDGEWORTHIA CHRYSANTHA.—A plant seldom seen in private collections is Edgworthia chrysantha. Its beautiful waxy, yellow flowers changing to white, have a pleasing fragrance during the winter and early spring months. If planted out in a cool house along with Daphne odora and Luculia gratissima, all these fragrant plants will flower well during a dull season of the year. Now is the best time to propagate the Edgworthia by inserting cuttings (which should be taken with a "heel" of the old wood) into small thumb pots filled with silver or coarse river sand, but having no hole at the base for drainage. Plunge the pots in a propagating frame having a moderate degree of bottom heat, and water them copiously twice daily. The cuttings will make roots in about three weeks' time if they are carefully shaded from bright sunshine. The Daphne and Luculia may be treated in a similar manner. *Wm. H. Jenkins, Northenden, Cheshire.*

NEW MELONS.—Although it is one of the regulations governing the action of the Fruit Committee of the Royal Horticultural Society that no awards can be made to any Melon by the committee unless previously grown for trial at Wisley, raisers still send fruits to Vincent Square. At a recent meeting two fruits named as new varieties were received and tasted, but had either been a second Diamond Jubilee it could have secured no award, according to the Council's regulations. But as those regulations are probably rarely seen by those who raise and send Melons, and some other subjects, I append the clause in Regulation 38 for their edification:—"No award will be made to Potatos, Peas, Beans, Tomatos, Cucumbers, Melons, and *similar* subjects, unless previously tested in the Society's gardens at Wisley as to their cropping qualities and distinctive merits." I put the word similar in italics because it is not made clear whether it applies to Melons only, or to all the kinds named. If it applies in that wide sense, then it seems doubtful as to what in vegetables the committee can deal with at the table. Naturally, with such conditions imposed, it should be arranged that a full trial of all the things named should take place every year. If such be not possible, then raisers will be handicapped in being deprived of their opportunity to secure the Society's awards. The two Melons sent recently had the too common fault of having two characters of flesh, the inner a soft watery pulp, the outer rather hard and unripe. The intercrossing of two diverse colours in Melons seldom produces other than these defects. *D.*

DEFINITION OF "AMATEUR."—A schedule of classes for the horticultural show to be held at the Franco-British Exhibition on June 24 and following days, such as should produce a very fine display, has just been issued. How far the liberal offer of medals made, or the less liberal sums as prizes may attract exhibitors remains to be seen. But the schedule includes "open" classes and classes for "amateurs." Seeing that anybody may compete in an open class no definition of status is needed. But when the term "amateur" is included, some definition of what the executive means by such a term should be given. The Royal Horticultural Society practically terms everyone as an amateur who is not a trader, including professional gardeners, who are, after all, but the agents of their employers. Other societies distinctly separate the professional gardener from the amateur. Possibly, for the show referred to, some definition of what is an amateur will be supplied. *A.*

Royal Horticultural Society.

THE TEMPLE SHOW.

MAY 26, 27 and 28.

THIIS important floral festival was held on the above dates. In the matter of weather the Society is to be congratulated, for although the opening day was somewhat dull it was not wet, and the second day saw perfect summer weather conditions. A slight difference of arrangement was seen in the tents this year, and they were conducive to the comfort of visitors, who appeared to be as numerous as ever, notwithstanding that the price for admission was raised on the opening day to ten shillings. As a flower show the exhibition was equal to any that have preceded it, but on this occasion no outstanding novelty was presented; this notwithstanding, awards to new plants were freely given. The exhibits of Orchids were quite equal to the best of former displays of these flowers at the Temple, and the same may be said of the Roses, hardy flowers, Begonias, and greenhouse subjects generally, whilst the Carnations were much in advance of those at any former Temple Show, partly because they have become more popular for decorative purposes as cut blooms. Messrs. Sander's new plants attracted considerable attention, and most of these have been already described in our columns. The management of this great exhibition was conducted without a hitch, and the thanks of the exhibitors and visitors are due to the officials, including the secretaries, the superintendent, Mr. Wright, Mr. Frank Reader, and the others. It was a matter of regret that the secretary, the Rev. W. W. Wilks, M.A., was absent from the exhibition through indisposition.

Orchid Committee.

Present: Harry J. Veitch, Esq. (in the Chair); and Messrs. Jas. O'Brien (hon. sec.), De B. Crawshay, R. Brooman-White, Sir Jeremiah Colman, H. Little, H. J. Chapman, C. J. Lucas, R. G. Thwaites, J. Wilson Potter, H. G. Alexander, W. Boxall, H. Ballantine, W. Thompson, A. Dye, W. Bolton, H. A. Tracy, N. C. Cookson, W. P. Bound, Gurney Wilson, F. J. Thorne, G. Shorland Ball, A. A. McBean, W. H. White, F. M. Ogilvie, J. Charlesworth, F. Sander, W. Cobb, and E. Ashworth.

There was a magnificent show of Orchids, the coveted Veitchian Cup being awarded to F. MENTEITH OGILVIE, Esq., The Shrubbery, Oxford, for a very fine group, admirably staged. Major G. L. Holford, C.I.E., C.V.O., who secured the cup last year, not being in competition.

Major G. L. HOLFORD, C.I.E., C.V.O., Westonbirt (gr. Mr. H. G. Alexander), occupied the first place on the right-hand side of the central stage in the large tent with a magnificent group of superbly-grown specimens staged in Mr. Alexander's usual excellent manner. The group was carried well up at the back, the sprays of Dendrobium Dalhousianum, large white Phalænopsis Rimestadtiana, Vanda teres, and other species mingling with the foliage of the Palms. Beneath these, in sections, were arranged a very fine selection of Lælio-Cattleyas, even the small plants being very heavily bloomed. Among the finest noted were Lælio-Cattleya Fascinator nobilior, with four spikes of 13 flowers; L.-C. Lustre magnifica, a brightly-coloured new hybrid; L.-C. Canhamiana Rex, a charming little specimen, bearing 12 white flowers with glowing crimson lip; L.-C. C. Wallaertiana, L.-C. G. S. Ball, L.-C. Elva, Westonbirt variety, a pretty new hybrid between Cattleya Warscewiczii and L.-C. Ingramii (see fig. 157); L.-C. Bedouin (L. purpurata × L.-C. Hycana), and varieties of L.-C. Aphrodite. Brasso-Cattleyas were represented by six distinct crosses bearing on the B. Digbyana hybrids 45 flowers, the handsome Westonbirt variety of B.-C. Digbyano-Mossiæ having eight large rose-tinted blooms. Miltonia vexillaria varieties staged in this group have never been equalled either for size or quality, the very healthy plants being densely set with flowers. Miltonia vexillaria virginale (see fig. 159) bore 10 spikes and 41 flowers; M. v. marmorata, three spikes of 17 flowers; two fine plants of the deep magenta-rose M. v. Empress Augusta Victoria 41 and 67 flowers respectively; M. v. Cobbiana, six spikes of 29 large, white-lipped blooms; M. v. Alfred, five spikes bearing together 27 flowers; a noble specimen of M. v. superbum bore 28 spikes with 134 flowers; and the handsome M. v. Westonbirt variety (see fig. 160), a companion of the famous M. v. Memoria G. D. Owen, two spikes with 10 flowers. Odontoglossums were very finely shown, the various specimens bearing over 100 spikes, with a total of upwards of 1,300 flowers, a plant of O. crispum having nine spikes with 124 flowers; another four spikes with 73 blooms. The fine varieties Madonna, Panther, Zoë Westonbirt variety, and other handsome forms bearing from 12 to 50 blooms each. The type of O. crispum grown at Westonbirt is good, and the manner in which the plants are developed to the highest degree presents them at their best. Cattleyas were very effectively displayed in the group, the pure white C. Dusseldorfei var. Undine raised at Westonbirt, of which 12 plants bearing together over 50 flowers were shown, being a telling feature. C. Mossiæ Westonbirt variety bore 22 fine flowers; the handsome C. M. Baroness, varieties of C. M. Reineckiana, the pure white C. M. Wageneri and its variety Mrs. E. Ashworth, and other fine forms were also shown, together with C. Skinneri alba, C. Warneri, varieties of C. Mendelii, C. Schilleriana Westonbirt variety, Lælia purpurata in fine varieties, including L. p. alba and L. p. Daintiness; L. majalis alba, a selection of Cypripediums, a grand lot of the orange-scarlet Masdevallia Veitchiana and the purple M. coccinea Harryana, Cochlioda Noezliana, and other showy specimens were also included.

Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate (gr. Mr. W. P. Bound), staged a splendid group on the other side of the stage at the entrance, a very large number of rare and interesting species being represented in the group, and a very fine selection of hybrids raised at Gatton Park. In the arrangement Mr. Bound displayed great skill, the rather narrow stretch of staging being made to present greater depth by the manner in which the elevated plants at the back of the group were arranged. High up among the tall Palms were the scarlet and orange-coloured heads of the useful hybrid Epidendrum Boundii, and the hybrids of it, E. Gatton orange and E. Gatton red, whose fine heads of bloom on tall reed-like stems well adapt them for decorative arrangement. Spathoglottis Colmanii and its varieties aurea and fulvissima gave bright yellow and red tints. Lælio-Cattleya Ruby Gem, L.-C. Highburyensis, L.-C. G. S. Ball, L.-C. Canhamiana alba var. Lady Edridge, and other varieties of L.-C. Canhamiana and L.-C. Nysa, all raised at Gatton Park, were very bright and variously coloured. In the centre of the group were fine specimens of Cymbidium Lowianum, together with the pretty pale greenish-yellow C. L. concolor Gatton Park variety; C. Colmaniæ and C. Lady Colman, two very pretty Gatton hybrids; and C. eburneo-Lowianum, in three very fine forms. Among these the deep reddish-scarlet Masdevallia Harryana Gatton Park variety and other richly-coloured forms and Renanthera Imschootiana gave bright colour. Odontoglossums were finely represented, the O. crispum having for the best O. c. Marjory Tyrrell Giles, a very pretty blotched variety; O. c. Mary Colman, also good and distinct; O. c. Colmaniæ, of fine shape and well marked; O. c. Lady Roxburgh, O. c. roseum-punctatum, O. c. purpureum, O. c. Rosy Queen, O. c. Richard Knight Causton, O. c. Colmanianum, and other rare forms. Other fine Odontoglossums noted were O. Wilckeanum The Don, O. W. Gatton Park variety, O. polyxanthum Gatton Park variety, O. triumphans aureum, the clear yellow O. Lindenii, now rare; O. cirrhosum Gatton Park variety, varieties of O. citrosmum, including the variety punctatissimum. Cattleyas were good and in great variety, those noted being C. Mossiæ Arnoldiana, C. M. Reineckiana "Major Lendy," C. M. Jeremiah Colman, a very handsome and distinct form; C. M. Horsmanni, and several other very distinct forms of C. Mossiæ; also good forms of C. Mendelii, C.

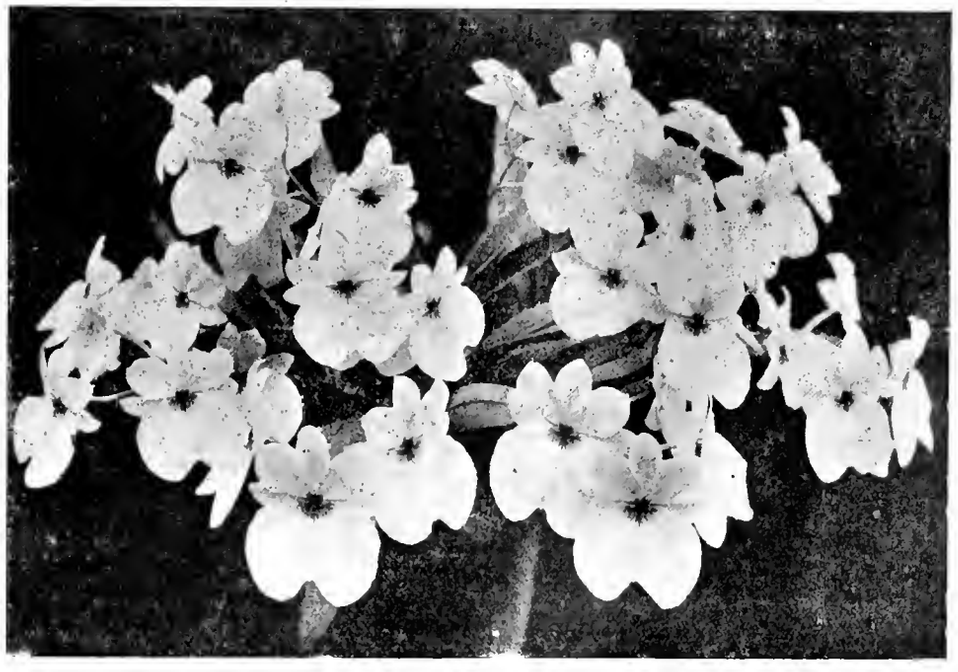

FIG. 159.—MILTONIA VEXILLARIA "VIRGINALE," AS EXHIBITED BY MAJOR HOLFORD AT THE TEMPLE SHOW.

Wm. Murray, and others. Miltonia vexillaria was represented by the varieties Colossus, Dainty, magnifica gigantea, and Cobbiana, all well bloomed; M. Bleauana Gatton Park variety was fine; so also were the varieties of Lælia purpurata. Other handsome plants remarked were Vanda teres Aurora and V. t. gigantea, the singular white Dia-Cattleya Colmanii, and several very interesting new hybrids of Diacrium bicornutum, Cypripedium Lawrenceanum Hyeanum, and other good Cypripediums; Cœlogyne Colmanii, some graceful Thunias, &c. Among specially interesting species of the order botanical, but many of them very curious and beautiful, were Cirrhopetalum gamosepalum, C. Cumingii, the fine C. pulchrum, Bulbophyllum Lobbii Colossus, B. Godseffianum, and the curious B. barbigerum.

F. Menteith Ogilvie, Esq., The Shrubbery, Oxford (gr. Mr. Balmforth), was awarded the Veitchian Cup for a magnificent group, admirable at all points, as well for the fine character of the exhibits as for the effective arrangement. The varieties of Miltonia vexillaria were splendidly shown, and among them M. v. Chelsiensis with six spikes, the white lipped M. v. virginale, and M. v. Cobbiana, and the finely-coloured M. v. Empress Augusta Victoria. On each side two arrangements of the emerald-green and white Cypripedium Lawrenceanum Hyeanum, C. callosum Sanderæ, and C. Maudiæ were very effective, no fewer than 50 flowers of C. callosum Sanderæ appearing. Besides them were a fine lot of the best coloured varieties of Cypripedium Lawrenceanum, including the variety Hackbridgense and a quantity of well-flowered plants of the pure white C. niveum and other Cypripediums. Among blotched forms of Odontoglossum crispum, O. c. Menteith was a grand flower, finely blotched, and of typical white and rose-tinted varieties; a very effective display of finely-grown, profusely-flowered plants was made. Hybrid Odontoglossums were good and numerous, one of the best being O. ardentissimum. The Shrubbery variety, a charming variety heavily blotched with deep reddish-purple, the tips and margins being white; and O. (cirrhosum × ardentissimum), a most floriferous and pretty hybrid. Other fine specimens noted were Cymbidium Devonianum with eight spikes, a good C. Lowianum concolor, Cattleya Skinneri alba, and a good selection of other showy Cattleyas, Cypripedium Honoriæ, &c.

Messrs. Sander & Sons, St. Albans, had a group of excellent quality. In the back was an arrangement of about 20 specimens of the large white Moth Orchid, Phalænopsis amabilis Rimestadtiana, beneath which were the scarlet Renanthera Imschootiana and Cochlioda Noezliana, and a profusion of pink and white Miltonia vexillaria. Cattleya Mendelii and various fine Odontoglossums entered largely into the composition of the group, which was most artistically arranged. Among the Odontoglossums, O. crispum festivum and O. c. transcendens, two blotched forms, with a new yellowish tint in the blotching, were noted; also O. c. Lusitania and O. c. Mauritania, two finely spotted forms, and among the numerous hybrids O. Lambeauianum, O. eximium, varieties of O. ardentissimum, and others of remarkable beauty. One of the finest plants in the show was Cymbidium Sanderæ, with a strong spike of several large white flowers, with crimson marking on the lip; in Aërides virens Sanderæ can be seen a rare albino, and A. Houlletianum, is uniformly pale yellow. Cattleya citrina maxima bore several large, wax-like yellow flowers; Dendrobium Bronckartii is a pretty new species, and the old Cattleya Skinneri and its white form, white C. Mossiæ, and other Cattleyas appeared to advantage. At one end a selection of plants of botanical interest included Masdevallia Obrieniana, M. xipheres, Vanda cœrulescens, Odontoglossum stellatum, Polystachya bracteosa, and other pretty species, and near them were a selection of the rare Odontoglossum platycheilum. Others of superior merit remarked were Cattleya Mendelii formosa, with a very fully coloured lip, and bearing four flowers; two good forms of the Odontonia Lairesseæ, illustrated in our last issue; Cattleya Niobe, of a very handsome type, &c.

Messrs. J. Cypher & Sons, Cheltenham, followed with a very fine group, in which Miltonia vexillaria, Lælia purpurata, and the large flowered Cattleyas predominated. Specially good were Miltonia vexillaria leucoglossa, and M. v. Empress Augusta Victoria; among Lælia purpurata the old L. p. Williamsii was the best. Cattleya Skinneri, varieties of Lælio-Cattleya Canhamiana, L.-C. Gannymede, the white Cattleya Dusseldorfei var. Undine, a fine selection of brightly-coloured Masdevallias, Cypripedium Maudiæ, C. Rothschildianum, good C. bellatulum, and other good things were also included.

Messrs. William Bull & Sons, King's Road, Chelsea, finished the staging on the same side with a group of Lælia purpurata, Cattleyas, Dendrobium thyrsiflorum, and other showy Orchids.

Messrs. Charlesworth & Co., Heaton, Bradford, staged a very remarkable group, rich in fine novelties in Odontoglossums, &c., the centre of attraction being their superb new Odontioda Charlesworthii, a marvellous flower of rich colouring (see Awards). At the back of the group, in the middle, was an arrangement of fine specimens of Vanda tricolor and V. suavis, such as are now seldom seen. Drooping around them were sprays of Oncidium macranthum and other graceful Oncidiums, and on each side fine forms of Lælia purpurata, Miltonia vexillaria, and banks of handsome Odontoglossums, of which O. Gladys, May Blossom (cirrhosum × Rolfeæ), and O. Eleanor (cirrhosum × Uro-Lambeauianum, O. Ossulstonii, and many others. Plants of special interest and well shown were Vanda cœrulescens, with many light blue flowers with violet lip; Bulbophyllum Godseffianum, Renanthera Imschootiana, with bright red flowers, a good specimen of Trichopilia tortilis, Epidendrum variegatum, the pretty little Physosiphon Loddigesii, with many sprays of dark orange flowers, the rare cream-white Dendrobium chlorops, and the blue D. Victoria Regina; Cœlogyne pandurata, Angræcum falcatum, A. Sanderianum, the rose-coloured Saccolabium ampullaceum, Vanda Bensoniæ, and of specially fine things the pale rose-spotted Cypripedium bellatulum Queen of Spain, the deep red-spotted Odontoglossum Phœbe magnificum.

Messrs. J. & A. McBean, Cooksbridge, the famous Odontoglossum crispum specialists, staged a group well worthy of them, the typical white forms of O. crispum being superb, and the blotched varieties very remarkable. Of these the central plant O. crispum Pride of Sussex was one of the finest known, its very large white flowers being almost covered with deep reddish-purple blotches, and in the front of the group the latest novelty, an unnamed form with the general features of O. c. Leonard Perfect, recently illustrated in the *Gardeners' Chronicle*, a very fine introduction. At the back were well-flowered Cymbidium Lowianum, in

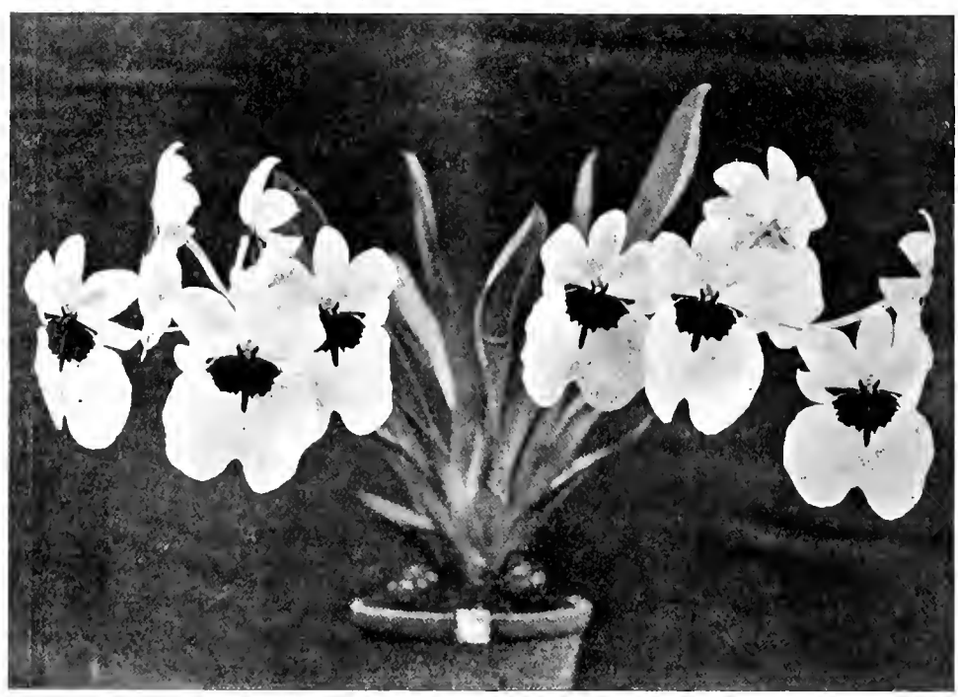

Fig. 160.—Miltonia vexillaria "Westonbirt variety," as exhibited by Major Holford at the Temple Show.

Skinneri) were two pretty novelties. Very pretty forms of O. Phœbe, and the fine Heaton strain of O. Rolfeæ, the pretty light-coloured O. amabile pallida, O. Othello Golden Gem, of a pale orange tint, and a large number of other handsome hybrid Odontoglossums were also represented. O. crispum were plentiful and good, some fine blotched forms being noted, the variety Président Fallières being very richly marked. Miltonia vexillaria alba, one of the finest pure white varieties; a grandly-flowered Cattleya Skinneri; fine forms of Lælio-Cattleya Fascinator; L.-C. Henry Greenwood, L.-C. Dominiana, and other Lælio-Cattleyas, three good specimens of the best white Cattleya Mossiæ Wageneri, and innumerable other fine Orchids were also included in this group.

Messrs. Moore, Ltd., Rawdon, Leeds, followed with a bright and interesting group, in which were excellent Odontoglossums and other favourite Orchids, and a selection of rare species of botanical interest. At the back were the long sprays of Cymbidium Lowianum, with the branched spikes of the yellow Oncidium Marshallianum, and other graceful species. Odontoglossum crispum were good and finely flowered, and some good spotted forms were included. Of the hybrids noted were good O. Phœbe, O. front of which was a very fine variety of the rare Oncidium superbiens, and others of its class. Beside them were good forms of Cattleya Mendelii and C. Mossiæ, some brilliant scarlet Cochlioda Noezliana, the heavily blotched Odontoglossum crispum F. K. Sander, the singularly marked O. crispum Rosslyn Sunset, and O. c. Sunrise, and a remarkably good Miltonia vexillaria Chelsiensis.

Messrs. Armstrong & Brown, Tunbridge Wells, had one of the most artistically arranged groups in the show, the alternate concave and convex outline being very effective. High up at the back was a grand specimen of Cœlogyne Dayana, with a large number of long drooping racemes of flowers. With it were sprays of the large yellow Oncidium macranthum, and around an effective arrangement of Odontoglossums and scarlet and red Masdevallias and Odontoglossums, the central ones being the handsomely-blotched O. ardentissimum var. Mrs. Temple; the cream-white O. Wilckeanum Urania, which has light cinnamon-brown blotches, good O. percultum, and other hybrid Odontoglossums, the clear white O. crispum virginale, and some nicely spotted forms. In the concave sides were selections of very fine Cypripediums, the best being C. Chamberlainianum magnificum, a

large and very dark coloured flower; C. callosum Sanderæ, some specially handsome C. bellatulum, &c.

Messrs. Hugh Low & Co., Enfield, completed the arrangement of that side of the central stage with a fine group, in which their superb strain of Cattleya Mendelii, which has produced so many fine forms, made the principal feature. Among their Cattleya Mossiæ the finest was C. M. Le Président, one of the best ever imported. Odontoglossums were also well shown by Messrs. Low, and of other good and rare things noted were Cirrhopetalum Wendlandianum, with long yellow and red flowers with fringed upper sepal and petals; the curious Oncidium unicorne and O. cornigerum, Dendrobium cymbidioides, D. Bensoniæ album, Diacrum bicornutum, Epidendrum prismatocarpum, with many spikes; the pure white Odontoglossum Pescatorei virginale, and Dendrobium albosanguineum.

Mons. Chas. Vuylsteke, Loochristi, Ghent, showed a selection of fine Odontoglossums, including the pretty blotched O. crispum Blushing Bride and O. c. Rainbow. For others see Awards.

Mons. Jules Hye de Crom, Coupure, Ghent (gr. M. J. Coene), showed his new Miltonia Hyeana, white with lilac mask at the base of the lip.

Baron Sir H. Schroder, The Dell, Egham (gr. Mr. Ballantine), sent the finely blotched

Fig. 161.—odontioda charlesworthii, awarded a first-class certificate at the temple show.

Odontoglossum crispum F. K. Sander, O. c. Doris, O. c. Veitchianum, O. c. Haroldianum, and the pretty hybrid O. Emma; also a fine plant of the handsome Miltonia vexillaria Memoria G. D. Owen.

Mr. J. Robson, Altrincham, showed fine Phalænopsis Rimestadtiana, Odontoglossums, a good white Cattleya, &c.

R. Ashworth, Esq., Newchurch, Manchester (gr. Mr. Pidsley), staged a small group of good Odontoglossums, &c., including O. crispum Black Prince (a very dark blotched form), O. c. Starlight, O. c. Marjorie, O. Pescatorei Charlesworthii, O. P. Ashworthii, &c.

Mrs. Collingwood, Lilburn Tower, Alnwick (gr. Mr. Lovett), showed a group of very finely-flowered Vanda teres.

H. S. Goodson, Esq., Fairlawn, Putney (gr. Mr. G. E. Day), showed Odontoglossum crispum Goodsoniæ and O. c. Président Fallieres, both handsomely blotched varieties.

Mr. J. Birchenall, Alderley Edge, Cheshire, sent a green and white form of Bollea Lalindei, a pretty blush-white Cattleya Mendelii, and Schlimmia trifida.

H. T. Pitt, Esq., Rosslyn, Stamford Hill (gr. Mr. Thurgood), showed Odontoglossum crispum xanthotes "Snow Queen."

Messrs. Jas. Veitch & Sons, Chelsea, arranged a nice selection of Odontoglossums, Cattleyas, &c., with their fine group of foliage plants.

AWARDS.

First-Class Certificates.

Lælio-Cattleya Elva Westonbirt variety (C. Warscewiczii × L.-C. Ingrami), from Major G. L. Holford, C.I.E., C.V.O. (gr. Mr. H. G. Alexander). A showy flower, with light rose-coloured sepals and petals, and deep ruby-crimson lip with a small pale yellow spot on each side of the disc. (See fig. 157.)

Cattleya Mendelii His Majesty, from Francis Wellesley, Esq., Westfield, Woking (gr. Mr. Hopkins). A superb Cattleya of great size, thick wax-like texture to the flower, perfect shape, and very delicate colouring. Sepals and petals blush-white; lip pure white with a yellow disc, in front of which is a small blotch of purplish-rose, the broad, crimped margin being white.

Odontioda Charlesworthii (Odontoglossum Harryanum × Cochlioda Noezliana) (see fig. 161), from Messrs. Charlesworth & Co., Heaton, Bradford. A great triumph for these patient Orchid hybridists, the plant in question being very beautiful, the flowers of good size and unique, almost indescribable in colour. The flowers in size and shape equal an ordinary Odontoglossum Pescatorei. In colour of a uniform deep ruby-crimson with a reddish glow when the light is raised, the spiny crest being yellow.

Odontoglossum illustre luxurians, from Mons. Chas. Vuylsteke, Ghent. Flowers large and of fine form, reddish-purple with white margin and tips.

Odontoglossum eximium Queen Alexandra, from Mons. Chas. Vuylsteke. Flowers deep reddish-purple, with slight lines and margin of white.

Cypripedium ventricosum, from Messrs. W. Cutbush & Son, Highgate. A very handsome, hardy species, native of Siberia, and allied to C. macranthum. The large ventricose labellum is deep rose colour.

Awards of Merit.

Odontioda St. Fuscien (Cochlioda Noezliana × Odontoglossum Adrianæ) (see fig. 162), from Mons. Henri Graire, St. Fuscien, Amiens, France. A very pretty hybrid, with a light yellow ground to the flower, closely blotched and margined with scarlet, the front of the lip tinged with rose.

Odontoglossum hibernicum (Hallii × hastilabium), from Messrs. Charlesworth & Co. An attractive novelty, with brown-barred sepals and petals and with sulphur-coloured tips. Lip brown at the base, white in front.

Cirrhopetalum pulchrum, from Sir Jeremiah Colman, Bart. A strong-growing species, with umbels of reddish flowers.

Odontoglossum laudatum, from Mons. Chas. Vuylsteke. A very handsome hybrid of rich colour and good form.

Odontoglossum crispum Kenneth, from Norman C. Cookson, Esq. (gr. Mr. H. J. Chapman). A very large white flower, heavily blotched with reddish-purple.

Odontoglossum Lindenii, from Sir Jeremiah Colman, Bart. (gr. Mr. W. P. Bound). The now rare clear yellow species formerly more frequently seen in gardens.

Cattleya Mossiæ "Le Président," from Messrs. Hugh Low & Co. A grand and finely-coloured variety, the very broad crimped lip being of a deep crimson-purple with light margin.

Botanical Certificate.

Bulbophyllum mirum, from Sir Jeremiah Colman, Bart. A very singular species (see fig. 156), with whitish flowers closely spotted with deep chocolate-purple, a whitish fringe decorating the sides of the central part of the flower. It is described by Mr. J. J. Smith and figured in *Icones Bogorienses*, tab. ccxxi., and recorded from Padang Pandjang, Sumatra. It is a remarkable and pretty species, the fringing with which the small nearly ordicular petals is furnished being very singular. (See fig. 156, p. 348.)

Cultural Commendation.

To Mr. H. G. Alexander, Orchid grower to Major G. L. Holford, C.I.E., C.V.O., for the splendid specimen of Miltonia vexillaria mentioned previously.

GROUPS OF STOVE AND GREENHOUSE PLANTS.

Messrs. Sander & Sons, St. Albans and Bruges, shared the honour with Messrs. James Veitch & Sons, Ltd., of presenting the most extensive collection of recently-introduced plants. They had their noted specimens of new and rare plants that won for them the premier position in the class for new plants at the recent Ghent Exhibition, most of which have formed the subjects of recent illustrations in the *Gardeners' Chronicle*. Others of much merit are Sansevieria Laurentii, a species with zebra-like marking and golden margins to the erect leaves; a variegated variety of Bougainvillea glabra; a magnificent specimen of Anthurium Scherzerianum, Bilbergia Forgetiana with green stripings and broad yellow bands on the handsome foliage; Furcræa Watsoniana, an Agave-like plant, the leaves of which have broad golden bands and a green margin; Polypodium Knightiæ, a Fern with long fronds, the pinnæ being laciniated, not unduly, but just sufficient for giving extra gracefulness to the plant; Linospadix Petrickiana; Anthurium Sanderi, with fine metallic green colour and lighter veining; Pandanus Sanderi var. superba, having handsome yellow and green striped leaves of great length; and Salmia Laucheana, a plant resembling a Ravenala with a leaf divided two-thirds from the apex and all the foliage arising in the same plane.

Messrs. James Veitch & Sons, Ltd., King's Road, Chelsea, made a bold exhibit with stove

Fig. 162.—odontioda st. fuscien, awarded an award of merit at the temple show.

and greenhouse plants, having chiefly handsome specimens of ornamental-leaved species, and with a number of flowering plants for relief. Fine examples of Caladiums, Anthuriums, Alocasias, Marantas, Codiæums (Crotons), and Dracænas formed the principal objects, and above these and interspersed with them were plants of Croton caudatus, C. tortilis, a handsome specimen of Nepenthes Mastersiana, Aralia triloba, and on either corner in the foreground magnificent examples of Dracæna Doucettii var. de Grootei. In addition was a fine plant of Medinilla magnifica, finely in flower, also brightly-coloured spathes of Anthuriums, a group of Odontoglossums, and other Orchids, Carnations, with Ferns, Palms, Asparagus, and numerous other pretty subjects. In the same tent, Messrs. Veitch exhibited hardy plants, the collection embracing many things of interest, some being quite new. There was a Rhubarb not yet in commerce named Rheum Alexandræ. This Chinese plant has small yellow leaves coloured like some of the Euphorbias.

Messrs. Wm. Bull & Sons, King's Road, Chelsea, showed a collection of ornamental-leaved plants of exotic species, the most prominent in which was a magnificent plant of Heliconia illustris. The large Canna-like foliage was beautifully coloured with its red striations and petiole. Two large well-grown plants of Dracæna Victoria were also noticeable, and, in addition, were Bertolonias, Caladiums, Aralias, Filicium decipiens, Asparagus, Palms, Ferns, &c.

Messrs. JAMES VEITCH & SONS, LTD., King's Road, Chelsea, had a large assortment of useful flowering plants suitable for indoor decoration. Many were of uncommon species, and all were worthy of notice. There were Streptocarpus in great numbers, mostly of the Achimenes-flowered type, and very large in their flowers; the range of colouring was wide. The uncommon Malvastrum grossulariæfolium were represented by many well-flowered plants. Kalanchoe was represented by K. flammea and K. kewensis ×, the latter exhibiting exceptionally fine heads of blooms. There were, as is usual in Messrs. VEITCH'S exhibit at these shows, a fine batch of handsome Phyllocactus. Mention must also be made of Amphicome Emodi, Coreopsis Grantii, Boronia heterophylla, Lantanas, Lobelia tenuior, and many plants of greenhouse Schizanthus.

Messrs. JAMES CARTER & CO., High Holborn, London, W.C., made an attractive display of florist's flowers at the entrance of the long tent near to the main gateway. Immediately on entering the tent was a group on either side, the one of brilliantly-flowered Cinerarias arranged as a bank with skill, and on the opposite side a rock garden furnished with suitable species. The central table facing the entrance was gay with Carnations, Begonias, Gloxinias, Cinerarias of the small-flowering strain, and Schizanthus. These latter plants were shown with flowers of many shades of colours, all so densely flowered that they appeared as masses of flowers. Schizanthus were also planted in hanging baskets that were suspended from a central festoon, along which was trained long growths of Smilax. The various subjects on the table were well blended for colour effect.

Messrs. HUGH LOW & CO., Bush Hill Park Nursery, Enfield, London, N., showed an assortment of showy flowering plants of greenhouse species, such as Ericas in variety, Chorizema, blue-flowered and other kinds of Hydrangeas, Boronias, Gazania splendens, Lotus pelorhyncus, the long trails of which bore numerous red flowers, and Gerbera Jamesonii. Interspersed in the exhibit were several large plants of the Bottle-Brush Tree, Meterosideros floribunda, and the showy-leaved Dracæna Victoria.

Messrs. H. B. MAY & SONS, The Nurseries, Upper Edmonton, showed a few flowering plants next to their fine group of Ferns.

Messrs. H. CANNELL & SONS, Swanley, Kent, showed a mixed group of flowering plants and a display of Cacti, including forms of Echinocactus, Cereus, Pilocereus, and Euphorbias. A brightly-flowered Bougainvillea named Maude Chettleurgh (see Supplementary Illustration to our issue for November 12, 1904), attracted attention. There was also a fine batch of herbaceous Calceolarias, Hydrangeas in small pots with huge inflorescences, Fuchsias in variety, and a group of Cannas. These last-named were not so fine as on some former occasions, but this, we were informed, was due to the backward season. We recorded as varieties of outstanding merit, Dr. Nansen, a dwarf-habited variety, having very pale yellow flowers; Julius Metz, suitable for bedding purposes on account of its dwarf growth; J. B. van der Schoot, yellow with red spots; Venus, rose-pink, a new shade in this flower; Prof. Dr. Balz, crimson with a yellow centre; Hesperide, orange; &c.

Messrs. SUTTON & SONS, Reading, occupied a prominent position in the largest tent with an exhibit of showy greenhouse flowering plants, including Gloxinias, Schizanthus, Calceolarias, Nemesias, Nicotianas, Begonias, &c. The display furnished the entire end of the marquee, and although the design was somewhat formal, the general effect was good. There were semi-circular bays of Schizanthus at either end, then others of herbaceous Calceolarias, with a central one of Cinerarias, principally of the "star" type. The intervening spaces were occupied with handsome Begonias of the tuberous-rooting kinds, Gloxinias of the erect-flowering type—all large, handsome plants, representing a choice strain of this flower, &c. There were several clumps of Nicotianas with coloured flowers, with Palms and Ferns for relief, and a finish to the group was formed by an edging of Grass in its seedling stage.

The beautiful Pelargonium Clorinda was never shown more effectively than in the magnificent group of these plants displayed by Mr. Edwin Beckett, gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree. There were about 15 plants, each of standard shape and trained to a stout bamboo stake.

A remarkably good and extensive group of Streptocarpus was staged from the same garden. The Aldenham strain of these plants is a choice one, and much improvement is manifest in the splendid range of colouring, size, and form seen in the flowers shown by Mr. GIBBS.

Hippeastrums.—A group consisting of about one hundred of these plants was staged by Messrs. KER & SONS, Aigburth Nursery, Liverpool. Dark-coloured varieties were arranged at the back of the exhibit with the lighter-flowered kinds in the foreground. Messrs. KER'S strain of these plants is of repute, and although not so fine perhaps as we have seen earlier in the season, they made a grand show, and found many admirers. Notable varieties were Empress Crimson, the name being significant of the colour; Virginia, a bold flower of rose colour; Virgin Queen, having four large expanded blooms each pale in colour and striped with rose; Cerise Queen and Margot, both of cerise colour; Zephyr, a pale-coloured variety, &c.

Gloxinias.—A group of these greenhouse plants was shown by Messrs. JOHN PEED & SONS, West Norwood, London, S.E. The flowers, although somewhat stiff, are excellent in their colouring and markings, some of the choicer kinds being especially attractive. Such are King Edward VII. (crimson), F. H. Goodwin (pale crimson), Lord Roberts (deep purple, a very fine variety), E. L. Peed (plum colour), Princess Ena (heliotrope veining), Howard Peed, and Countess of Carnarvon.

Messrs. SUTTON & SONS, and Messrs. CARTER & Co. both made extensive exhibits of these plants in their groups referred to above.

Begonias.—One of the choicest of these exhibits was put up by Messrs. BLACKMORE & LANGDON, Twerton Hill Nursery, Bath. The group was not over large, but of sufficient size to embrace most of the best kinds in commerce, and every plant was worthy of inclusion. A pretty feature was provided in three baskets suspended from tall iron supports, and furnished with the varieties Fleur de Chrysantheme (pink), Alice Manning (yellow), and Carmina (carmine). These have trailing growths that hang down, bearing their pretty flowers freely. Among the tuberous-rooting section mention may be made of Lady Tweedmouth, the rose-salmon petals being crenated at their margins; Percy Foster (scarlet), Col. Turnor (crimson), Princess Mary (orange, edged with pink), Duchess of Portland, Pink Pearl, and Brilliant.

Mr. JOHN R. BOX, West Wickham and Croydon, displayed a group of tuberous-rooting Begonias, making a special feature of varieties having crimped margins. Of this section may be mentioned Mrs. Cole Child (coppery red), Mrs. Pankhurst (yellow), Glory (orange), and Mme. Tettazzini, a new variety of pink colouring. Of the commoner type mention may be made of Mrs. Barclay Walker, Miss Alice Attrill, Queen Alexandra and Rev. Canon Horsley, the flowers of which were shades of salmon colour; Scarlet Queen, and Miss P. Moule.

Another choice group of these plants was exhibited by Messrs. T. S. WARE, LTD., Feltham, Middlesex. The group was one of the most extensive devoted to these flowers, and they were shown in excellent condition. We may select as choicer kinds Maud Wolland (apricot), Wm. Marshall (scarlet), Marchioness of Bute (white), Lady Ebury (salmon-red), Sonning Joy (cerise), Mrs. Geo. Pike (crimson), King Edward VII. (crimson), Mrs. Moger (a delicate salmon colour), and Dr. Clement Godson (rosy salmon).

Mr. A. LL. GWILLIM, Cambria Nursery, New Eltham, Kent, contributed an exhibit of tuberous-rooting Begonias, all finely flowered and exhibiting excellence of culture. The group was prettily arranged, and embraced, amongst other varieties, Mrs. J. C. Gwillim (salmon-red), Oriflamme, with crinkled petals, the colour being red; Mrs. H. Harris, the wavy petals being very large and coloured orange-pink; Mrs. Moger, of Camellia shape and a handsome shade of salmon or pink; Marguerite Gwillim, yellow, &c. There was also a selection of single-flowered kinds, and several having pupillæ-like outgrowths on the segments. The whole was relieved with Ferns and Asparagus species.

A group of Begonias was also displayed by Messrs. JOHN LAING & SONS, Forest Hill, London, the plants being well displayed and not crowded.

CALADIUM.

Messrs. JOHN LAING & SONS, Forest Hill, made an interesting show of Caladium, the plants ranging from 2 feet to 4 feet in height. Very striking in colouring were Mrs. Laing, having a white ground and crimson netting, edged green; The Mikado, having leaves with a crimson centre, and green-bordered; bicolor sericeum, rather lighter in tint than the last-named; Orphie, candidum, Gerald Dow (a big crimson leaf), Reine de Danemarck, and King Haakon (with foliage almost white).

Messrs. J. VEITCH & SONS, LTD., Royal Exotic Nursery, Chelsea, showed, in association with other fine foliage plants, splendid specimens of Caladium, and of these we append the names of the more striking varieties: Henry Lovatt, Reine de Danemarck, Thomas Tomlinson (a very beautiful leaf), Gustave Cruyer (one of the finest of the crimson-leaved kinds), Rose Laing, Souvenir de M. J. Burn, Baron de Rothschild, Princess of Teck, and Sir Henry Irving.

Messrs. JOHN PEED & SON, West Norwood, London, S.E., showed a number of large-leaved Caladium, all of exquisite colouring and very delicate in appearance. Massed against a groundwork of greenery composed of Adiantum Ferns, the beautiful leaves appeared to advantage, the tints ranging from red through many shades to almost white, and not the least beautiful were those having green tints. Mme. Marie de Flacourt is of delicate colouring, being a suffusion of rose on the creamy lamina with an indication of green in some of the veining. Henry Lovatt commanded attention in its lovely red and green tinting. John Peed is also worthy of inclusion amongst the best kinds.

CLEMATIS.

Messrs. G. JACKMAN & SON, Woking Nursery, Surrey, showed a grand group of Clematis in variety. The brightest colours were observed in Ville de Lyon, King Edward VII., Molly Moser, the flower in this case having a rose-pink band on a white ground. Henry is quite white, all but the anthers; Lord Neville is still unbeaten as a large-flowered purple Clematis. Jackmanii rubra has a strikingly fine crimson-purple tint. Among double-flowered varieties mention should be made of Belle of Woking, a white flower with a shade of purple pervading it.

Messrs. R. SMITH & CO., St. John's Nurseries, Worcester, had a fine exhibit of Clematis. Of double-flowered varieties we remarked Enchantress (white), Venus, and Victrix (pale lilac). Among single-flowered Clematis, King Edward VII., Fairy Queen, Lawsoniana, Mrs. G. Jackman (white), Sensation (a rich satiny-mauve), and Beauty of Worcester are deserving of general cultivation.

A small collection of Clematis was shown by Mr. L. R. RUSSELL, Richmond Nurseries, Richmond, Surrey.

CARNATIONS.

A fine group of Souvenir de la Malmaison Carnations, each plant carrying four to six blooms each, was shown by CECIL F. RAPHAEL, Esq., Porter's Park, Shenley, Herts. (gr. Mr. Grubb). This group consisted of the varieties Princess of Wales (old rose), Maggie Hudson (deep crimson), King Arthur (scarlet), and the type having flowers of a pale flesh tint.

Messrs. CUTBUSH & SONS, Highgate, London, N., and Barnet, exhibited small groups consisting of Carnations in each, and these were shown of one variety over a groundwork of varieties of Rosa polyantha, the effect being remarkably good. We may mention such fine varieties as the Pasha (an orange and scarlet flower), Mrs. Martin R. Smith (a rich pink "Malmaison"), Francis Samuelson (a scarlet flower with an orange tint—a taking colour), Elf King (one of those indescribable purplish tints that would go well with mourning attire), Baldwin (large bloom of a deep pink colour), Cecilia (pale lemon-yellow, double, and good of shape), Maggie Hudson, Marmion (a light-tinted

"fancy" of the "Malmaison" form, the florets edged with white, and having white at the base), Mercia (crimson flower of large size), King Arthur, &c.

In their group of ornamental foliaged plants Messrs. J. VEITCH & SONS, LTD., Royal Exotic Nursery, Chelsea, set up neat, round groups of tree Carnations of such varieties as Winsor, Enchantress (both pink and white-flowered), the curiously-coloured Mikado, Deacon (a scarlet flower of middle size and fairly full), the lovely Lady Bountiful, &c. These Carnation groups harmonised exceedingly with the bright tints of foliage and flower surrounding them. "Malmaison" Carnations were set up to the number of 18 large plants, carrying 20 and more large blooms.

Messrs. HUGH LOW & Co., Bush Hill Park Nurseries, Middlesex, excelled any of their previous displays of Carnations, these, as cut blooms, being shown in extraordinary profusion. We noticed the various forms and tints of Enchantress, White Perfection, Lady Rose (a "Malmaison," with spoon-shaped florets), Mrs. Burnett (one of the prettiest flowers), Victory (a vivid scarlet flower), Winsor, Princess of Wales, &c.

Mr. W. H. PAGE, Langley Nurseries, Hampton, exhibited a group in which we noted the scarlet-flowered Beacon, very fine Princess of Wales, Lady Bountiful, Britannia, Mrs. H. J. Brooks (a small, neat white bloom), Aristocrat, President Roosevelt, and the old esteemed variety, Uriah Pike.

Mr. C. F. WATERS, Balcombe, Sussex, made another exhibit of the same extent as the last-named. The finest display was made with Princess of Wales, and many of the finer varieties of the Souvenir de la Malmaison type now grown were noted. Of less well-known varieties mention may be made of Helen Goddard (a flower of a cerise colour), Lady Rose, Aurora, Lady Grimston, Glendale, &c.

Mr. H. BURNETT, Carnation specialist, Guernsey, showed Carnations in profusion, and of the highest quality. Most of them were so fine that it was very difficult to make a selection. Mrs. H. Burnett is the finest variety of its colour rose-pink. R. Craig, Mrs. Lawson, and the variegated form of this variety, and Mikado were excellent; Winsor and many unnamed seedlings.

Mr. C. ENGELMANN, Hornybrook Nursery, Saffron Walden, made a moderate display with most of the favourite varieties of the day: Jessica (a fancy with scarlet stripes), Harlowarden, Enchantress in variety, Pink Patten (a flower with flat petals and sufficiently double to be a good flower).

Messrs. BELL & SHELDON, Castle Nursery, Guernsey, had a fine exhibit of choice varieties, including Beacon, Enchantress, Evangeline (a very fine double, pale pink flower), Sensation, Harlowarden, Winsor, &c. These Guernsey flowers seem to excel in brightness of colour.

Mr. S. MORTIMER, nurseryman, Rowledge, Farnham, Surrey, showed a large number of Carnations of native and American origin. We noted Flamingo, Victory, The Belle (a neat white bloom), Fair Maid (one of the flat floretted section, of a very pale pink tint), Adonis (a bright scarlet), and several of the older varieties.

Mr. THOS. WARE, LTD., Feltham, Middlesex, made a small display, and among the more popular sorts we observed the novelty Conway (a flower of fair size and of a soft rose-pink tint). Winsor, Enchantress, and other favourites were the preponderating varieties.

Mr. A. F. DUTTON, The Nurseries, Iver, Bucks., made one of the more important exhibits of Carnations. Besides the usual varieties seen in collections, which were admirable specimens of cut blooms, we noted Mabelle (a flower having flat petals of an old rose tint), Pink Imperial (cerise), Red Riding Hood (a fine scarlet flower), Imperial (having rosy-red flakes on a suffused pink ground), and Aristocrat.

Messrs. G. & A. CLARK, LTD., The Nurseries, Dover, had an exhibit of American and English varieties of Carnations. They showed the new variety Burswood (a scarlet-coloured Carnation).

W. JAMES, Esq., Chichester (gr. Mr. W. H. Smith), showed a fine group of Carnations, and adjoining these was a number of tree Pæonies shown by the same exhibitor.

ROSES.

Mr. CHARLES TURNER, Royal Nurseries, Slough, displayed Roses in great numbers, and of many sections. There were dwarf bushes of Teas, Hybrid Teas, and Hybrid Perpetuals, of Rambler Roses, Polyantha Roses, both single flowered and double flowered. The biggest blooms of any of the Roses were those of Princess C. de Ligne, which measured 7 inches in diameter, a loosely-built bloom. The blooms of Frau Karl Druschki were also of great size, and those of Pierre Notting, a flower resembling a Maréchal Niel in tint. The blooms of Madame Victor Verdier were good. Mrs. E. Mawley, a Tea Rose, has a dull pink tint; the variety Bessie Brown was well shown on a standard plant; Merveille de Lyon, Niphetos, Mrs. R. G. Sharman-Crawford, and Souvenir de Madame Eugene Verdier were excellent. The show of plants was magnificent.

Messrs. PAUL & SON, The Old Nurseries, Cheshunt, made a charming display with a corner group in the largest tent. It was arranged with a low foreground of dwarf bush Roses, Teas, Hybrid Teas, and H.P.s. Of these we may call attention to Wm. Shean, a H.T.; Mrs. Miles Kennedy, a grand Tea of a creamy white, tinged with orange in the centre; Yvonne Vacherot, a creamy white flower of Niphetos shape; and very fine blooms of Cherry Ripe, Ulrich Brunner, Elizabeth Barnes, Mildred Grant, Nellie Johnstone, and Richmond, which were especially worthy of notice. Among these dwarf Roses, and in a triple line at the rear, standard, pillar, umbrella, and other forms in which Roses look well were disposed, and these consisted of Polyantha and Rambler varieties, blooming in great profusion. Rose Wichuraiana var. Lady Godiva opens with a pink coloured centre and changes to white; Rosa Polyantha Martha is of a bright pink shade and semi-double. The H.T. Dorothy Page Roberts is a flower of a sprawling form when it expands, and as such it may find admirers; the colour is uncommon—a salmon-pink. H.T. Dean Hole is pretty as a bud, but it must be caught young.

Messrs. W. CUTBUSH & SON, Highgate, N., had dispersed among their pink and white-flowered dwarf Rosa Polyantha tall, slender plants of such Ramblers as Dorothy Perkins, Hiawatha, Rose Paradise, Mrs. F. W. Flight, &c. The effect was excellent, and there were many encomiums from the visitors.

Messrs. H. CANNELL & SONS, Swanley, Kent, exhibited a bank of dwarf plants of Rambler Roses, including Mme. N. Levavasseur (Baby Rambler), Lady Gay, Debutante, Hiawatha, Crimson Rambler, and American Pillar, a large-sized single-flowered Rose.

Mr. G. PRINCE, of Oxford showed tall and dwarf Rambler Roses, among them a new variety named Lady Violet Henderson, a white semi-double Rose, that is said to be a continuous bloomer; Mrs. Longworth, a sport from Caroline Testout, a flower of pink and white tints, full before it is fully open (new); The Lion, H.T., a pretty filbert-shaped bloom of a salmon-pink colour, with a tint of copper in it; Delight is a new variety of Rosa Wichuraiana, pink, with a white centre, the flowers of the build of Hiawatha.

Messrs. W. PAUL & SON, Nurseries, Waltham Cross, made a somewhat similar display, but larger. There were the same Rambler Roses in tall examples, splendidly flowered. Beneath these there were arranged pot Roses of Teas, Hybrid Teas, Hybrid Perpetuals, &c., with flowers as fine as possible. Dora, a H.T., had blooms nearly 6 inches in diameter, and which were very full and compact. A plant of Frau Karl Druschki carried a dozen fine blooms. Marquise de Sinety (H.T.), a beautiful globular flower, full and above the usual size; the colour a shade of pink, should become a favourite. Aennchen Muller is a new form of R. polyantha, with voluted petals. The display of dwarf potted plants of the finest varieties was of the best. Elaine, a H.T., pure white, a fine bedder, obtained an Award of Merit.

Mr. G. MOUNT, Nurseryman, Canterbury, made a small exhibit of Roses of the choicest kinds, and in the finest possible condition. Unusually fine were Mrs. John Laing, Ulrich Brunner, Joseph Lowe (H.T.), a sport from Mrs. W. J. Grant; Richmond, and Frau Karl Druschki. Rambler Roses in variety as standards, arches, and pillars, formed the back of the stand.

Messrs. B. R. CANT & SONS, Colchester, made a show of cut blooms of Roses, backing them with tall Rambler Roses. The cut blooms consisted chiefly of admired varieties of Teas, Hybrid Teas, and Hybrid Perpetuals, and shown in the best condition. A boxful of Maréchal Niel were very meritorious.

Messrs. HUGH LOW & Co., Bush Hill Park, Middlesex, had an exhibition of Roses on the grass in the open air, Ramblers forming the bulk of the plants, and these were present in quite dwarf as well as tall plants.

RHODODENDRONS AND AZALEAS.

Messrs. JOHN WATERER & SONS, LTD., Bagshot, Surrey, showed hardy Rhododendrons in many beautiful varieties. They displayed the beautiful Pink Pearl in excellent condition, the sprays being crowned with the huge pink-coloured blooms. Francis B. Hayes, white, with chocolate-red markings; Francis Waterer, red (as a standard plant); Marquis of Waterford, a beautiful specimen, with long pyramidal inflorescences of a pleasing red colour, with deeper-coloured margins; Mrs. Holford, Kate Waterer, Cynthia, Prometheus, Gomer Waterer, and a host of others of equal beauty.

Mr. CHAS. TURNER, Royal Nurseries, Slough, had a number of pyramidal-trained plants of Azalea indica. The white Madeleine, Apollo (red), Comte de Chambord (soft pink, with splashings of deep pink in the upper petals), Roi d'Holland (red), Vervæneana (a semi-double variety, having pink colouring on a white ground), Mme. Van Houtte (of perfect form), and Roi d'Holland (red) are a selection of the best varieties shown.

Messrs. R. & G. CUTHBERT, Southgate, Middlesex, displayed a very large group of Azaleas of the Mollis, sinensis, and Ghent or pontica types, with hybrids of these species. They also showed some handsome varieties of the occidentalis breed, notably a new variety labelled Magnifica. The clusters of bloom in this variety are fragrant, the upper petal having yellow markings, the other segments being white. Another variety named Graciosa will be found described under Awards. We also noticed Fanny, pale lemon spotted with orange; Nancy Waterer, a fine yellow-flowered kind; hybrids of the Altaclerense type, with flowers of exceptional beauty; Peter Koster, Consul Ceresole, &c.

Mr. R. GILL, Tremough, Cornwall, brought trusses of Rhododendrons and other plants from his noted gardens, which enjoy a favoured climate. There were magnificent "heads" of R. Falconeri, R. Aucklandii, Beauty of Tremough, Gill's Goliath, Gill's Triumph, the unique R. Roylei, and a new variety in R. Gillii, with deep rose-coloured flowers.

Messrs. H. LANE & SON, Berkhamsted, contributed Rhododendrons as pot plants, amongst which we noticed good examples of Cynthia, Purity, and the double-flowered form of R. fastuosum.

HERBACEOUS AND ALPINE PLANTS AND CUT FLOWERS.

In the exhibits of hardy plants there is little fresh to record, and it would almost appear that any great advance, so far as the extent and quality of the subjects are concerned, must be a matter of great difficulty. In certain directions, while the exhibits as a whole display great care in their preparation, the same care has not in every case been extended to the method of arranging the subjects. Rock gardens and improvised rockery arrangements have become a feature at the Temple Show, and while these arrangements are certainly good in some instances, and very suggestive in others, it is curious to note how a moisture-loving subject can be placed high and dry on an exposed rockery, whilst an encrusted Saxifraga—fit subject for a rocky ledge—should find itself with Trilliums or allied things in quite wet situations, or among bog plants. A rock-garden exhibit should be the subject of much thought and careful treatment, and nature should be copied as faithfully as may be possible. But taken collectively, the displaying of the exhibits was good, while their numbers and their quality generally, in a season by no means too favourable, affords the best proof of the increasing popularity of these hardy

plants. Inside the entrance to No. 1 tent Messrs. Carter & Co., High Holborn, arranged, as in former years a rock-garden exhibit planted freely with choice and suitable Alpines, such as Phloxes, Saxifragas, Primulas, Aubrietias, &c. Examples of Saxifraga pyramidalis were especially pleasing. Near by Messrs. Wm. Artindale & Son, Sheffield, had a showy group of herbaceous subjects, amongst which Primula japonica, Ranunculus aconitifolius, Gerberas, Cypripedium calceolus, and other plants were prominent.

Mr. R. Farrer, Craven Nursery, Clapham, Yorks., exhibited a delightful assortment of the choicest Alpines, arranged with judgment and skill. In this exhibit it was apparent that the person who was responsible for it possessed an intimate knowledge of the plants and their natural environment, and cranny and crevice alike had its quota of the choice things displayed. Thus were seen Ramondias, Androsace villosa, A. sarmentosa, A. Chumbyi, Edraianthus serpyllifolius, with its rich violet "cups" or "bells"; the lovely Daphne rupestris, exceptionally rich in colour; Primula farinosa, Gentiana verna, many delightful Saxifragas, and, not least, one of the boldest displays of Trillium grandiflorum ever brought to the Temple Show. A few suitable shrubs completed a very charming and decidedly instructive bit of grouping.

Messrs. J. Cheal & Sons, Crawley, had a bolder arrangement, suggestive somewhat of the natural rock unearthed. Bold prominences and recesses were alike skilfully treated and suitably planted with such plants as Erinus, Tiarella, Pinguiculas, Sarracenias, Dianthus neglectus, Edraianthus serpyllifolius, &c.

Messrs. George Bunyard & Co., Maidstone, contributed a fine display of herbaceous cut flowers and Tulips; such things as Eremuri, Irises in great variety, Pæonies, Genms, Meconopsis cambrica, Saxifraga Cotyledon pyramidalis, single and double Pyrethrums and Gerbera Jamesonii may be instanced as affording abundant proof of the representative character of the group. The Tulips alone were a great feature, and were much admired.

Mr. John R. Box, West Wickham, contributed a small rockery, pleasingly arranged with Alpines and allied plants.

Mr. Amos Perry, Enfield, showed a collection that was largely composed of the more showy perennials disposed in handsome colonies with occasional breaks and recesses of choice things arranged in a natural manner. The finer of the Liliums, as L. Hansonii, L. auratum, L. speciosum in variety, L. testaceum, and L. longiflorum, were seen to advantage, while the more hardy Sarracenias, as S. flava, S. f. rubra, S. variabilis, and S. purpurea, were associated with a small arrangement of Water Lilies, Aponogeton, &c., with Gunnera and other water-loving plants in the background. Hardy Cypripediums, choice Primulas, including P. pulverulenta and P. Cockburniana, the pretty Calochorti, and stately Eremuri were also noted, while the newer forms of Phlox canadensis occupied a prominent place. Tulips, too, presented a blaze of colour at the one end of the group.

Mr. B. Ladhams, Shirley, Southampton, included in his group such excellent things as Incarvillea grandiflora, Aquilegia Stuartii, together with Rehmannia angulata, tree Pæonies, &c.

The Misses E. & M. Kipping, Hutton, Essex, had a small but prettily-arranged rockery, on which were arranged Alpine, herbaceous and flowering shrubs.

The collection of hardy plants from Mr. G. Reuthe, Keston, Kent, was of a more comprehensive character, and in addition to a large assortment of small Alpines in pots, was seen a very handsome collection of the finer species of Rhododendrons. Embothrium coccineum in full beauty. Droseras, hardy Cypripediums, a rare Himalayan Saxifraga, S. Brunoniana, pretty groups of Ramondia, the rare Dryas Drummondii with pleasing yellow flowers, Mertensia lanceolata, pretty colonies of Primulas, Androsaces, the curious Clintonia borealis and many more beautiful, rare, and interesting plants.

Showy Oriental Poppies in many varieties were well displayed by Mr. W. J. Godfrey, Exmouth, Devon; while Mr. N. Lowis, Bridgewater, had near by a fine group of the beautiful St. Brigid Anemones.

Messrs. Gunn & Sons, Olton, near Birmingham, had an excellent collection of Phloxes, including P. suffruticosa and P. decussata in variety, the former including such beautiful varieties as White Swan and Mrs. Hunter, the latter perhaps one of the most beautiful of its class. The white flowers are of good form, and have a pink centre. In the centre of the group was a fine batch of the purple-flowered Viola cornuta.

Mr. M. Prichard, Christchurch, Hants, arranged a capital collection of the more showy herbaceous species chiefly as cut flowers. He made prominent displays of the beautiful Scilla nutans in many good varieties, single and double Pyrethrums, Spanish and other Irises, Oriental Poppies, the earlier-flowering Pæonies, Eremurus, Anemone sylvestris, &c. Among dwarfer plants we noticed Saxifraga Aizoon lutea, S. A. rosea, Dianthus glacialis, Veronica rupestris alba (a delightful plant), and many more.

A very showy and interesting array of herbaceous plants, choice shrubs, &c., were well staged by Mr. R. C. Notcutt, Woodbridge, Suffolk. The group included fine examples of the yellow-flowered Piptanthus nepalensis, Viburnum macrocephalum, Berberis Knightii (a strongly-spined species with clusters of clear yellow flowers), the white-flowered Azalea latifolia, said to be quite hardy, together with Pyrethrums, Thalictrum aquilegifolium, Cheiranthus Allioni, Irises, &c.

Mr. J. Forbes, Hawick, displayed freely Pansies, Polyanthuses, Pentstemons, and other hardy plants in a good group.

Messrs. Lister & Son, Rothesay, showed a collection of Violas in many shades of colour, a somewhat exceptional group of Ixias, also Sparaxis and Irises of several sections.

Early-flowering Gladioli came from the nursery of Mr. Lilley, Guernsey, who also had plants of the curious Arum crinitum.

The Misses Hopkins, Shepperton-on-Thames, displayed in a free manner on a rockwork exhibit, Phloxes, hardy Cypripediums, Primulas, Saxifragas, and other plants of a similar character.

The King's Acre Nursery Company, Ltd., Hereford, had a showy group of perennials in flower, amongst which were Incarvilleas, Phlox canadensis, Saxifraga Cotyledon pyramidalis, and other hardy plants in variety.

Tulips in many kinds and in good condition came from Messrs. Wm. Bull & Sons, Chelsea.

Messrs. R. Smith & Sons, Worcester, set up a mixed arrangement of Irises, Tulips, early Gladioli, and other plants.

A capital arrangement of Alpines with rock-shrubs and herbaceous plants was staged by Messrs. Geo. Jackman & Sons, Woking. We noticed varieties of Primulas, Columbines, Heucheras, also Gentiana verna, the pretty Daphne Cneorum, Lithospermum Gastonii, Ranunculus aconitifolius (double-flowered variety), Trilliums in variety, single and double Pyrethrums, &c. The method of grouping was well carried out in this exhibit.

Messrs. Barr & Sons, Covent Garden, London, W.C., had a very extensive and comprehensive group, which included choice Alpine and herbaceous plants and perhaps one of the most gorgeous displays of Tulips ever seen at a Temple show. The blooms of these bulbous plants were in every way excellent, and quite remarkable in a season like the present. The Darwin and May-flowering sorts naturally predominated, and among them we noted such handsome yellow-flowered sorts as Inglescombe Yellow and Walter T. Ware, a pair difficult to excel at this season; also Zulu Sophrosyne, Orange Beauty, Lord Curzon, Clara Butt, Salmon Prince, and Louis XIV. Apart from these were many of the English or old florists' Tulips in good condition. In addition, Ixias, Cypripediums, Early Gladioli, Irises of many sections, Primulas, Columbines, &c., were shown in considerable numbers. One of the showiest things in the collection was the orange-coloured Dimorphotheca aurantiaca, a pretty annual from the Cape, having Marguerite-like blossoms some 2 inches in diameter.

Lady Northcliffe, Sutton Place, Guildford (gr. Mr. J. Goatley), had a group of seedling plants in flower of the somewhat rare Meconopsis racemosa. The colours are exceedingly variable, and certainly not so showy as the originally introduced species.

A very excellent group of the perpetual-flowering Pink Progress was shown by Mr. C. H. Herbert, Acock's Green, near Birmingham. The plant is obviously a good grower, producing strong stems fully 2 feet in length, on which are borne handsome, fragrant, perfectly-formed flowers of Lilac pink colour. The plant is worthy of inclusion in gardens.

Mr. J. Walker, Thame, Oxon, had a very interesting collection of the English or florist's type of Tulips.

Messrs. Gilbert & Son, Bourne, Lincolnshire, exhibited a rich display of Anemones in many showy varieties. Hardy plants, with Tulips, were freely displayed by Messrs. G. & A. Clark, Dover, the group including not a few of the more showy herbaceous subjects. A collection of tufted Pansies and Violettas was shown by Mr. Howard Crane, Archway Road, Highgate, N. They formed a feature near one of the entrances to No. 1 tent. The blossoms were pleasingly arranged in pans in a somewhat natural manner, and in this way displayed both their beauty and value to advantage. There were some three or four dozen of these pans, containing as many different sorts, the group, and especially its arrangement, exciting a good deal of interest. The Violettas were exceedingly charming, having a miniature, almost Alpine character of growth, and they are very free in flowering.

Messrs. Baker's, Wolverhampton, had a very extensive grouping of Alpines, Liliums, and other showy subjects as Primula japonica, P. pulverulenta, Trilliums, Incarvilleas, in addition to a very handsome collection of bedding and other Pansies displayed in pyramidal sprays.

Messrs. Hogg & Robertson, Dublin, had a delightful display of Tulips of the Parrot, Darwin, May-flowering, and other sections.

A group of Alpine, rock-shrubs, and other hardy plants was shown by Mr. A. R. Upton, the Hardy Plant Nursery, Guildford. The collection was full of interest, and was arranged with taste and skill. Primulas, Gentians, Saxifragas, Androsaces, Ramondia, Haberlea, &c., were displayed with freedom, and gave an excellent estimate of their value in the rock-garden.

The large collection of Darwin and other Tulips from Mr. Alex. M. Wilson, East Keal Manor, Spilsby, was one of the finest of its kind ever staged, and of a very representative character, the giant cups impressing all by their boldness and beauty.

Messrs. R. H. Bath, Ltd., Wisbech, also showed a rich and varied collection of Tulips displayed to advantage.

Tree Pæonies and single and double Pyrethrums were shown by Messrs. Jas. Kelway & Son, Langport, Somerset. In the large Orchid tent, Messrs. R. W. Wallace & Co., Colchester, in addition to a very fine lot of Tulips, arranged a group of herbaceous and bulbous plants in flower. Liliums were well represented in such species as L. Hansonii, L. testaceum, L. Monadelphum Szovitzianum, &c., while Irises of many kinds, Incarvilleas, Heucheras, the scarlet Habranthus pratensis, with Ixias, Anchusa italica "Opal," Eremuri, and others, contributed to an excellent group of the best and most worthy hardy garden subjects.

SWEET PEAS.

Mr. C. W. Breadmore, Winchester, showed bunches of Sweet Peas in excellent condition, the sprays of blossoms being of a good colour and well flowered. Some of the finest varieties were Helen Lewis (of a rich orange tone), Miss Willmott, Etta Dyke (perhaps the finest white variety in commerce), Elsie Herbert (an edged flower of white and rose), Mrs. Collier (cream), King Alfonso (deep carmine), and Audrey Crier (pink).

Messrs. G. Stark & Co., Great Ryburgh, Norfolk, had a small exhibit of these flowers, the finer blooms being Mrs. W. King, Helen Lewis, Queen Alexandra (rich carmine), and Gladys Unwin (pink).

Messrs. Robert Sydenham, Ltd., Tenby Street, Birmingham, had a display of Sweet Peas, of which the best varieties were Navy Blue, King Edward VII. (rich carmine), Paradise (pink), Herbert Smith (carmine rose), and Scarlet Gem (a variety very rich in colour).

Messrs. E. W. King & Co., Coggeshall, Essex, exhibited Mrs. W. King (rose), Helen Lewis, Queen Alexandra (rich carmine), and others of merit.

FERNS.

Messrs. H. B. MAY & SONS, Edmonton, arranged an imposing group of choice species and varieties of Ferns. The space for staging being limited, the plants were arranged to a great height. Nephrolepis, shown on tall standards, had long drooping fronds, whilst Davallias, grown on tall stems, were also imposing. The new plumose forms of Nephrolepis were a feature. The latest addition, N. exaltata Amorpohlii, is certainly one of the most beautiful Ferns in existence. N. elegantissima, N. Whitmanii, N. superba, and N. todæoides are all grand Ferns. Pteris Summersii and P. Childsii are beautiful plumose varieties. Pteris aspericaulis, Lomaria L'Herminieri, Adiantum macrophyllum albo-striatum, Didymochlæna truncatula, Adiantum Veitchii, Gymnogrammes, and Polypodium Mayi gave pretty shades of colour to the group. Polypodium Knightiæ, Acrostichum aureum, Goniophlebium subauriculatum, Platyceriums, Drymoglossum spathulatum, Polypodium vaccinifolium, Asplenium obtusilobum, and others on tree trunks were all well cultivated and shown in the best possible condition. The climbing Lygodium was also well shown.

In the open ground Messrs. MAY also arranged a pleasing group of hardy Ferns. The North American Osmundas were well shown, and crested Scolopendriums were a great feature. Of varieties, we may instance S. ramocristatum, S. corymbiferum, S. digitatum marginatum grandiceps, S. cristulatum, and the curious little S. densum, all of which were very pretty. Athyrium Filix-fœmina plumosum multifidum, one of the finest of the Lady Ferns, A. F.-f. cristulatum, A. F.-f. formoso-cristatum, Pteris aquilina conglomerata (a pretty variety of the common Bracken Fern), Cyrtomium falcatum Mayi, Lomaria chilensis, Polystichum angulare diversilobum grande, and other choice varieties were all well shown.

Messrs. SANDER & SONS, St. Albans, exhibited Adiantum species nova, a very distinct Fern from Columbia. The frond somewhat resembled A. lunulatum, but they were larger and of more substance than that species. A grand specimen of Polypodium Knightiæ was also shown by this firm.

Messrs. J. HILL & SON, Lower Edmonton, staged a very fine group of Ferns, in the centre of which was a grand specimen of Platycerium grande. There were also fine plants of P. Willinckii, P. Hillii, and P. Veitchii, Nephrolepis Amorpohlii, N. todæoides, and N. amabile (a new variety), Adiantum Veitchii, A. cyclosorum, A. tinctum, A. macrophyllum, A. renforme, Asplenium multilobatum (a very distinct new species), Osmunda javanica, and Davallias in several choice varieties. Filmy Ferns included examples of Trichomanes crispum, Todea superba and other choice sorts.

THE OUTDOOR EXHIBITS.

These were as full of interest as those of previous shows, but, generally speaking, there was more diversity in the style of arrangement. This was partly caused by the fact that it was found necessary to diminish the extent of space allowed along the paths for individual exhibits, and the depth was increased to compensate for this. Some alteration was consequently compulsory where the groups were large.

Near the north entrance to the Orchid tent, Messrs. J. VEITCH & SONS, Chelsea, had two handsome groups of plants most effectively arranged, all presenting considerable variety in colour and habit. A few pyramidal and standard Bays in tubs helped to diversify the general form, and the bases of the taller specimens were surrounded by brilliant yellow, orange, salmon, and red hardy Azaleas; contrasting with these were groups of the pure-white Viburnum macrocephalum and a large white Clematis. Brilliant colours were furnished by plants of Rose Hiawatha and other varieties. Amongst smaller notable exhibits in this collection were admirable examples of the delicate pinkish Statice Suworowii, with long, cylindrical, interesting spikes of flowers. The Blue Hydrangea Hortensia, various ornamental species of Vitis, many Primulas, including P. japonica, P. pulverulenta, and P. Veitchii; also the yellow Meconopsis integrifolia and the rose-flowered Rehmannia angulata were all conspicuous.

Myosotidium nobile was admirably shown by J. D. ENYS, Esq., Enys, Cornwall. The plants were in three large tubs about 2½ feet in diameter, the leaves large and glossy green, and a dozen or more heads of pink and blue flowers.

The Bottle-Brush tree—Metrosideros floribunda—was in strong evidence, Messrs. HUGH LOW & CO., Bush Hill Park, contributing a group of 40 or 50 specimens in pots. Some were in dwarf bush form, with 20 or 30 brilliant red heads of flowers, and others were in standard style. The decorative value was heightened by the free use of variegated plants as a margin in the group. Carnations and Rambler Roses also formed two beautiful groups from Messrs. HUGH LOW & CO., in both cases the background was formed of standard Bays, but the flowering plants were very informally and tastefully displayed, many telling varieties being included.

Messrs. DAVID RUSSELL & SON, Brentwood, exhibited an extensive collection of hardy shrubs and ornamental trees, with Roses, Rhododendrons, Azaleas, and Viburnums. Shrubs and other plants, with variegated or golden-coloured foliage, were very conspicuous, the species Dimorphanthus mandschuricus standing out boldly, together with Maples of many kinds.

Pigmy Japanese trees from Messrs. J. CARTER & Co., High Holborn, again commanded a large share of attention, and a considerable variety of forms was represented, both in an old and a young state; the dark shades of the Conifers were relieved by the coppery or green tints of Japanese Maples.

The water garden and group of hardy plants arranged by Messrs. WM. CUTBUSH & SONS, Highgate, was one of the special feature of the display outside the tents, and an admirable effect was produced. The Japanese Irises and Osmundas had an excellent appearance on the border of a pond of water. Liliums, Eremuri, Lupins, and Pæonies, with the Dropmore variety of Anchusa italica, and white Campanulas helped the general effect. On the higher point of the background hardy Azaleas and Rhododendrons were massed, with Japanese Maples and Bamboos. In the front of the group collections of Incarvillea grandiflora, with large crimson flowers, the blue Phlox Laphamii and hardy Cypripediums were notable; especially conspicuous amongst the latter was the deep crimson-purple Cypripedium ventricosum, for which a First-Class Certificate was awarded. Groups of glowing scarlet Vallota purpurea, a new Coleus with peculiar large red verrucose leaves named Cordelia, and the soft-tinted Astilbe (Spiræa) Peach Blossom were additional attractions.

Mr. AMOS PERRY, Enfield Nurseries, exhibited groups of the blue Phlox canadensis Perry's variety, in contrast with the darker but smaller Laphamii—both useful and distinct, the former being particularly floriferous. Several other choice hardy plants were shown at the ends of these groups.

Mr. L. R. RUSSELL, Richmond Nurseries, Surrey, supplied a charming group of ornamental shrubs and trees, arranged in an uncommon manner with a curving path through the collection; they also furnished a fine margin to one of the entrances to the large tent. Golden leaved trees were prominent, especially Quercus concordia, Golden Standard Ivies, Cornus alba Spathii, and Golden Maples. The rich dark copper Beech (Fagus sylvatica purpurea), the copper Hazel, and the silvery Elæagnus macrophylla imparted diversity of colour, while many Genistas, Cytisus, and Ceanothus also furnished floral attractions.

Messrs. J. CHEAL & SONS, Crawley, arranged a choice and handsome collection of ornamental shrubs and trees, with flowering plants, in a novel and effective manner. The front part was in semi-circular form, a narrow path separating this from the taller background. Oaks, Maples, Beeches, Aralias, Clematis, Rhododendrons, Azaleas, and Lilacs were the chief features.

Messrs. RICHARD SMITH & CO., Worcester, showed a fine collection of Rhododendrons, Lilacs, Azaleas, and various ornamental shrubs and trees, which had many admirers. Rhododendron Pink Pearl, in the centre of the group, was a conspicuous favourite.

Japanese Maples were grandly represented in a group from Messrs. W. FROMOW & SONS, Chiswick. The plants were healthy, and showed the wonderful diversity in leaf-form and colouration, which distinguish these graceful plants, to perfection. The majority were in the form of standards, especially the red-leaved varieties, but some of the finely-cut bright green forms, like dissectum palmatifolium, were shown both as bushes and standards.

Messrs. JOHN WATERER & SONS, LTD., Bagshot, contributed specimen Hollies, Rhododendrons in choice varieties, Kalmias, and various Conifers. The group was boldly and effectively arranged, and the Rhododendrons comprised many choice varieties.

Messrs. T. CRIPPS & SON, LTD., Tunbridge Wells, had a group of Japanese Maples in excellent condition, the red and yellow forms being most prominent, and with them were tall specimens of ornamental vines and a few Conifers. This was a very charming group, and might have had more space with advantage.

Tasteful examples of rockeries from Messrs. PULHAM & SONS, 71, Newman Street, Oxford Street, occupied a large corner near the Embankment entrance, and indicated in an unpretentious but effective way the methods this firm adopt with such good results.

Messrs. WM. CUTBUSH & SON, Highgate, had an extensive collection of examples of topiary work, chiefly in Box and Yew. With them were tall standard conical Bays and other trees. A great variety of forms was included, and they attracted the attention of many visitors.

Choice Alpine and herbaceous plants from Mr. MAURICE PRICHARD, Christchurch, filled a table in the grounds. Amongst them were numerous varieties of hardy subjects, Aubrietias, Saxifragas, and Dodecatheons, all interesting and pretty.

Messrs. BARR & SONS, King Street, Covent Garden, filled a large amount of table space with Japanese pigmy trees in all their grotesque forms, several exceeding 100 years in age, though not more than 2 or 3 feet high. Japanese Maples, similarly diversified, were also included, together with the elegant but seldom seen Zelkova acuminata.

Messrs. H. B. MAY & SONS, Upper Edmonton, exhibited the brilliant scarlet Salvia Pride of Zurich, a number of new Coleus, and handsome Verbenas, with Lobelias, Heliotropes, &c.

Mr. G. REUTHE, Keston, Kent, showed a small collection of hardy plants, amongst which the brilliant blue Gentiana verna was notable amongst other choice Alpines.

Mr. W. PINGO HORTON, Cravenhurst, Seaford, Sussex, showed a small collection of Alpine and herbaceous plants, arranged on cork-edged shelves.

MISCELLANEOUS EXHIBITS.

Mr. A. J. A. BRUCE, Chorlton-cum-Hardy, showed a collection of insectivorous plants of hardy kinds, including Sarracenias, Darlingtonias, Droseras, and Dioneas. Many of the Sarracenias and Darlingtonias were pleasingly marked in their upper parts, and some were coloured deep red. There were many named varieties of the various species in this meritorious exhibit, and all the plants exhibited excellence of culture.

A large batch of show or Regal Pelargoniums was put up by Mr. W. J. GODFREY, Exmouth, Devon.

Messrs. BAKER'S, Wolverhampton, showed a large assortment of Violas and Pansies in numerous varieties, also Lily of the Valley, Primulas, Spiræas, &c.

The KING'S ACRE NURSERY CO., Hereford, showed Carnations, Schizanthus, and Heliotropes. These latter flowers were in variety, some having relatively huge inflorescences, notably those labelled Argus and Anthys. The same firm showed a pretty rose-coloured Petunia.

Messrs. HEATH & SON, Cheltenham, showed many well-flowered plants of show Pelargoniums.

Herbaceous Calceolarias were finely shown by Messrs. WEBB & SONS, Wordsley, Stourbridge. The plants were crowned with their large flower heads, the flowers representing all the shades seen in this useful decorative subject.

Messrs. J. GARRAWAY & CO., Clifton, Bristol, showed a group of plants of their noted strain of Schizanthus wisetonensis.

Messrs. JARMAN & CO., Chard, displayed their pretty hybrid Centaureas in white, heliotrope, and yellow-coloured flowers.

Messrs. W. & J. Brown, Stamford, displayed Verbenas, Heliotropes, Cytisus, Ageratums, Roses, Lotus peliorhyncus, and other subjects of a like nature.

Messrs. Geo. Paul & Son, Cheshunt, showed Lilacs in variety, a plant of Lonicera Hildebrandtii in flower, an ornamental-leaved Catalpa named C. syringifolia pulverulenta, a grand plant, in a pot, of Hydrangea arborescens, &c.

Mr. Jannoch, Dersingham, Norfolk, showed Lilacs in variety, an outstanding plant being one of the white Mme. Lemoine variety, the flowers of which are duplicated in their petals. Mr. Jannoch also showed Lily of the Valley.

Mr. W. J. Godfrey, Exmouth, Devon, displayed several named varieties of Verbenas, the most promising of which was the beautiful kind named after Miss Willmott.

Roberts, T. W. Turner, W. P. Thomson, H. J. Cutbush, Chas. Blick, Chas. T. Druery, W. G. Baker, W. Bain, N. F. Barnes, Chas. Dixon, J. W. Barr, Jas. Walker, Edward Mawley, and R. Hooper Pearson.

AWARDS.

First-Class Certificates.

Dracæna Doucettii var. De Grootei.—A handsome ornamental-leaved plant, with long, narrow leaves rather more than 1 inch in their widest part. The lower leaves curve gracefully downward, the others being erect, together forming a stove plant of exceptional beauty. The long, narrow leaves are margined and striped with yellow, the mid-rib being red, and this colour is suffused through the lower portion of the foliage. Shown by Messrs. James Veitch & Sons, Ltd., Chelsea.

Tulip Walter T. Ware.—This is a handsome flowers. Shown by Messrs. R. & G. Cuthbert, Southgate.

Begonia Empress Marie.—A large flowered white variety of the tuberous-rooting section. The blooms are of the Camellia form, and the petals have handsome waved outlines. Shown by Messrs. Blackmore & Langdon, Twerton Nursery, Bath.

Codiæum (Croton) Fred Sander.—This beautiful yellow and green variety was described in our issue for April 25, p. 258, and illustrated on p. 275 in the succeeding number.

Rose Elaine.—A dwarf-habited Hybrid Tea variety, white with a faint trace of rose, especially in the younger blooms. The form of the flower is good, the petals being much reflexed. Shown by Messrs. W. Paul & Sons, Waltham Cross.

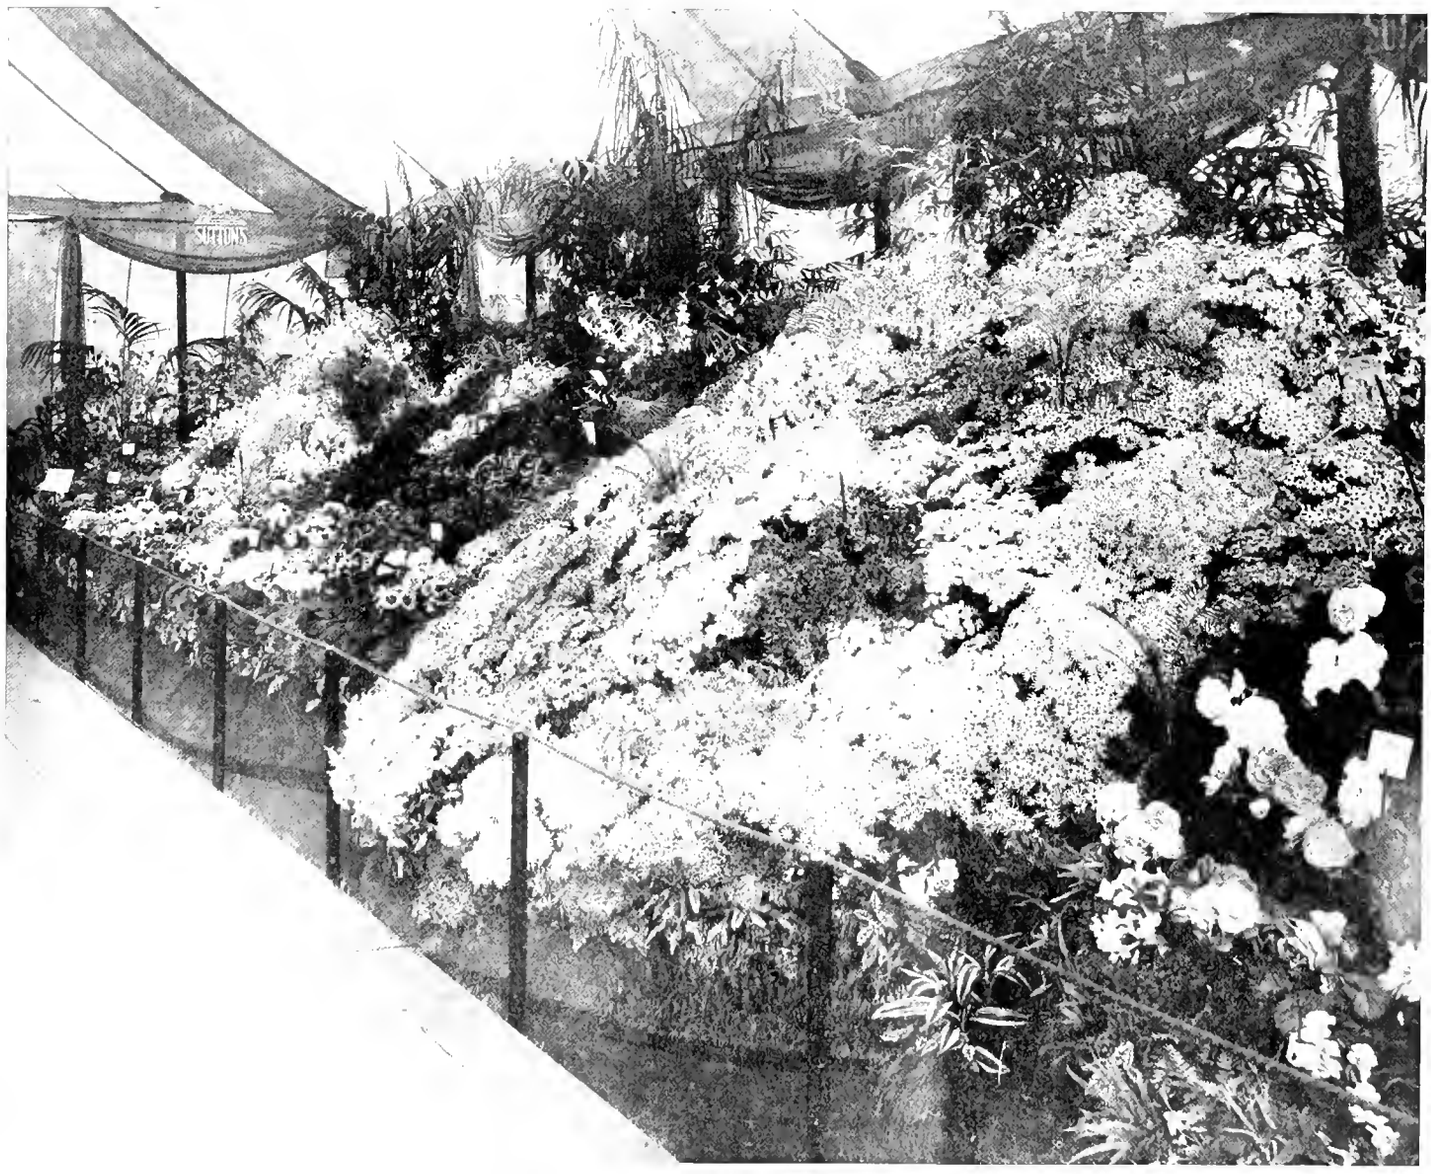

Fig. 163.—Messrs. Sutton and Sons' exhibit of cinerarias, gloxinias and other plants at the temple show.

Messrs. W. H. Rogers & Son, Ltd., Red Lodge Nursery, Bassett, Southampton, made a small exhibit of Rhododendrons, Astilbe (Spiræa), and Clematis montana rubens.

Messrs. W. Paul & Son, Waltham Cross, Herts., had trusses of Rhododendrons of hardy varieties, bunches of Lilacs, and the yellow-flowered Genista hispanica.

Mr. W. R. Chaplin, Jovinges Nursery, Waltham Cross, exhibited Petunia

Floral Committee.

Present: W. Marshall, Esq. (Chairman), and Messrs. W. J. James, W. Cuthbertson, G. Reuthe, (Jno. Green, C. J. Salter, F. Page

May-flowering variety that has previously received an Award of Merit, and on account of its general excellence it was granted a First-Class Certificate on this occasion. The colour is deep golden-orange of a shade probably unique among late-flowered kinds. Shown by Mr. Walter T. Ware, Bath, and Messrs. Barr & Sons, Covent Garden.

Awards of Merit.

Azalea amœna alpha "gracilis."—Large trusses of blooms, white with blotchings of yellow on the upper petals are the characteristics of this fine variety. The blooms are fragrant, and there is a suspicion of rose in the younger

Rose Tausendschon.—An excellent rambling Rose with rose-pink blooms hanging in large bunches from the ends of long side growths. Some of the inflorescences measured more than 9 inches in diameter, and for this class of Rose the individual blooms are also large. The plant is a free grower, and has bright foliage of very healthy appearance. Shown by Messrs. W. Paul & Sons, and Hobbies, Ltd., Dereham, Norfolk.

Rose White Dorothy.—A white climbing Wichuraiana variety, said to be a sport of the popular Dorothy Perkins variety. Shown by Messrs. Paul & Sons, Cheshunt, and Messrs. B. Cant & Sons, Colchester.

Dimorphotheca aurantiaca.—This plant is a showy and beautiful annual from the Cape, with Marguerite-like blossoms 2 inches or more in diameter, coloured a rich orange-gold, and rendered the more conspicuous by the rather dark coloured disc. The plant, as shown, is about 18 inches high, neat in habit, and profuse in its flowering. From Messrs. BARR & SONS, Covent Garden.

Pæonia decora alba.—A single-flowered variety like P. Emodii, with rounded petals that are cupped, and giving a saucer-like outline to the flower. From Messrs. R. W. WALLACE & Co., Colchester.

Tulip Duchess of Westminster.—A very handsome rose-coloured Darwin Tulip with shapely flowers that are delicately tinged with pinkish-white near the edges. It is a conspicuous variety in a selection of these bulbous flowers. From Mr. ALEX. M. DICKSON, East Keal Manor, Spilsby.

FRUIT.

For so huge an exhibition, the display of fruit was very meagre, being limited to three trade collections, not a single private garden being represented by an exhibit. Such a deficiency is apt to lead strangers to British horticulture to assume that the food products of gardening are lightly esteemed, when compared with the marvellous wealth of flowering material seen on every hand. To assume so much is to materially undervalue British fruit culture under glass. Still its comparative non-representation on this occasion calls for remark.

Messrs. THOS. RIVERS & SONS, Sawbridgeworth, as usual, had in the large Orchid tent one of their customary collections of fruit trees in pots. There were some three dozen Peach, Nectarine, and Cherry trees of large size, all in fine fruit. The Peaches were both first early varieties being Duke of York and Duchess of Cornwall; the Nectarines were all of that superb variety Cardinal, and the Cherries were Early Rivers, Frogmore Bigarreau, and Elton. There were also several small Fig trees and a collection in pots of the Citrus family.

Messrs. G. BUNYARD & Co., Maidstone, staged a remarkable collection of 100 dishes and baskets of well-preserved Apples, and, apart from the general excellence of the samples, the way they had been preserved created wide interest. These dishes were backed by several pot trees of the early Cherry Guigne d'Annonay. Specially fine Apples were Calville Rouge, High Canons, Smart's Prince Albert, Ontario, Belle de Pontoise, Calville Malingre, Wagener, Calville des Femmes (large and handsome), Newton Wonder, Norfolk Beefing, Alfriston, Prince Alfred (very fine), Farmer's Seedling, Bramley's Seedling, Tibbett's Pearmain, King of Tompkins' County, Lane's Prince Albert, Mère de Ménage, Winter Queening, Belle Dubois (very fine), Gabalva, Beauty of Herts, and Brownlees's Russet; also Pears Belle des Arbes and Easter Orange.

Messrs. LAXTON BROTHERS, Bedford, sent up a most attractive collection of Strawberries of picked samples. There were 16 baskets and dishes, and two dozen plants in fine fruit. These latter comprised Laxton's Pineapple, Epicure (rich dark fruits), and Bedford Champion. In addition to the above, Royal Sovereign was largely represented. The firm added to the exhibit in dozens, in baskets, superb fruits of Early Alexander Peach and Cardinal Nectarine, and a few dishes of brown Turkey Figs.

VEGETABLES

were moderately shown, only trade or market products being presented. The most interesting collection certainly was one of Messrs. SUTTON & SONS, Reading, of Potato tubers and plants of divers species in pots. The tuber display comprised 52 varieties, shown in dishes, the product of planting in frames on beds of leaves giving very mild warmth on February 26. None were large, but all were of most acceptable table size. Of those kidney-shaped and specially noticeable were Gladiator, Superlative, May Queen, White Beauty of Hebron, Myatt's and Sutton's Ashleafs, Seedling 159, and Supreme, whilst of coloured kidneys, King Edward VII., Purple Eyes, and Mr Bresee were the best. Of white, round forms, British Queen, Up-to-Date, Sutton's Seedling, Sir J. Llewellyn, Abundance, Nonsuch, Ideal, Harbinger, and Early Puritan were good, and of coloured rounds, Reading Russett, Lord Tennyson, The Dean, and the Sutton Flourball. The pot plants included those of Blue Giant and Commersonii Violet to show identity, and of species S. Commersonii from Uruguay, and other forms; S. etuberosum, with foliage most resembling that of the garden Potato; S. maglia, S. tuberosum, S. verrucosum, and others.

Messrs. WATKINS & SIMPSON, Henrietta Street, London, sent a collection of imported vegetables, the most meritorious of which was a number of fine white solid heads of Cauliflower Early Six Weeks. There were numerous bunches of Early Frame Carrot, Early Long White Radishes, and Romaine Early Frame Cos and Cold Frame Cabbage Lettuces, neither good-hearted samples.

An interesting collection came from the Thatcham Fruit and Flower Farm, Berks, of glass-grown samples, prominent amongst which were numerous bunches of Early Frame Carrot, similar to what had been seen in the imported collection. There were quantities of the long white Marteau Turnip, like Jersey Navel, very good Paris white Cos Lettuce, white Dutch Cabbage Lettuce, and French Breakfast Radishes. These products were stated to have been grown on the "Maraiber" systems.

Very fine oval-shaped bundles of Asparagus came from Mr. R. STEVENSON, Burwell, Cambridge; oblong bundles from Mr. GODFREY, and round bundles from Mr. HARWOOD, both of Colchester, all the samples being remarkably fine.

Awards made by the Council.

VEITCHIAN CUP.

F. Menteith Ogilvie, Esq., for Orchids.

GOLD MEDALS.

J. Veitch & Sons, Ltd., for foliage plants, flowers, &c.; W. Cutbush & Son, for Roses, Carnations, Alpines; Sander & Son, for Orchids and foliage plants; Charlesworth & Co., for Orchids; Major G. L. Holford, C.I.E., C.V.O., for Orchids; Hugh Low & Co., for Orchids, Carnations, &c.

SILVER-GILT FLORA MEDAL.

T. S. Ware, Ltd., for Begonias and Carnations; H. Cannell & Sons, for Roses, Calceolarias, Cannas, &c.; J. Carter & Co., for flowering plants; G. Mount, for Roses; Hobbies, Ltd., for Roses, G. Reuthe, for herbaceous plants, &c., Alex. Dickson and Sons, Ltd., for Tulips; J. Hill & Son, for Ferns; A. J. A. Bruce, for Sarracenias; Armstrong & Brown, for Orchids, H. Burnett, for Carnations, A. F. Dutton, for Carnations; R. Ashworth, for Orchids.

SILVER-GILT KNIGHTIAN MEDAL.

T. Rivers & Sons, for fruit trees in pots; Laxton Bros., for Strawberries.

SILVER CUPS.

Sutton & Sons, for miscellaneous plants; Barr & Sons, for herbaceous plants; G. Bunyard & Co., Ltd., for herbaceous plants and fruit; J. Waterer & Sons, for Rhododendrons, &c.; May & Sons, for Ferns, &c.; L. R. Russell, for Clematis, shrubs, &c.; R. Smith & Co., for Clematis and herbaceous plants, C. Turner, for Roses and Azaleas; G. Paul & Sons, for Roses, &c.; Jackman & Son, for herbaceous plants; Pulham & Son, for Alpines, &c.; J. Cheal & Sons, for trees, shrubs, and herbaceous plants, W. Paul & Son, for Roses, &c.; T. Cripps & Son, for Acers, &c.; R. P. Ker & Sons, for Hippeastrums, A. Perry, for herbaceous plants; R. & G. Cuthbert, for Azaleas, &c.; Hon. V. Gibbs, for Pelargoniums and Streptocarpus; C. F. Raphael, for Carnations, &c.; Blackmore & Langdon, for Begonias; R. Wallace & Co., for herbaceous plants; Sir J. Colman, Bart., for Orchids; W. James, Esq., for Carnations and Peonies, J. Cypher & Sons, for Orchids, &c.; M. Prichard, for herbaceous plants.

SILVER-GILT BANKSIAN MEDALS.

J. Peed & Son, for Caladiums and Gloxinias; Baker's, for herbaceous plants, J. R. Box, for Begonias; Craven Nursery Co., for Alpines; Fromow & Sons, for trees, shrubs, &c.; R. C. Notcutt, for herbaceous plants.

SILVER LINDLEY MEDAL.

F. Menteith Ogilvie, Esq., for Orchids.

SILVER KNIGHTIAN MEDALS.

Thatcham Fruit Farm, for vegetables, Stephenson, for Asparagus.

SILVER FLORA MEDALS.

F. Cant & Co., for Roses, D. Russell & Son, for trees, shrubs, &c.; J. Laing & Sons, for Begonias, Caladiums, &c.; C. W. Breadmore, for Sweet Peas, A. R. Upton, for herbaceous plants; Webb & Son, for Calceolarias; B. R. Cant & Sons, for Roses, Dobbie & Co., for Violas, &c.; Hogg & Robertson, for Tulips; J. & A. McBean, for Orchids; J. W. Moore, for Orchids; R. Gill, for Rhododendrons.

SILVER BANKSIAN MEDALS.

J. D. Enys, for plants of Myosotidium; W. P. Horton, for Alpines; King's Acre Nurseries Co., for herbaceous plants; A. M. Wilson, for Tulips; W. Bull & Sons, for Orchids and foliage plants; H. Crane, for Violas; Misses Hopkins, for Alpines, &c.; F. Lilley, for bulbous plants; G. Prince & Co., for Roses; Watkins & Simpson, for vegetables; R. H. Bath & Co., Ltd., for Tulips and Carnations; A. H. Gwillim, for Begonias; A. J. Harwood, for Asparagus; T. Jannock, for Lilacs, &c.; B. Ladhams, Ltd., for herbaceous plants; W. H. Page, for Carnations; Bell & Sheldon, for Carnations.

MARKETS.

COVENT GARDEN, May 27.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—ED.]

REMARKS.—Tasmanian and Australian Apples are arriving in large quantities, and their prices are easier except for the choicest samples. The demand for Strawberries this week has been good, notwithstanding increased supplies. There is also an improvement in the Grape trade. Asparagus, both home-grown and French, is considerably cheaper. Cherries in boxes and half-sieves from France are selling freely at reduced prices. *E. H. K., Covent Garden, Wednesday, May 27, 1908.*

COVENT GARDEN FLOWER MARKET.

The warmer weather has materially improved trade. The sale of summer bedding plants has militated against the disposal of hardy flower roots, and many growers are left with stocks unsold. The warmer weather has caused flowers to develop rapidly. Liliums have been very cheap, but they may advance in value any day. This morning (Wednesday) their prices showed a slight rise, and I found on visiting some growers a few days since that the stocks of retarded bulbs were nearly exhausted. This week will nearly see the finish of the Narcissus season. Gladioli are very good, but it is only the varieties of Colvillei that are seen. One grower informs me that he has G. Brenchleyensis almost ready to cut. Irises are now prominent. I. germanica in some colours sells well if the flowers are cut early. The Spanish Irises also make better prices when they are cut before the blooms are well advanced. Iceland Poppies are very good, but some growers will not cut them until the flowers are open, and when the salesmen unpack them many of the flowers drop. English growers are sending some good double white Stocks. Stephanotis, Gardenias, and Callas are plentiful, but very few Eucharis have been seen for some time.

POT PLANTS.

There is no great change to record in this department. The nurserymen are sending in large quantities of bedding plants, and they have been selling fairly well. Trade in hardy shrubs, climbers, &c., is not very good. Hydrangea paniculata is good, also H. Hortensia and the variety Thos. Hogg. H. Mariesii with flowers of a blue shade are in demand. Intermediate Stocks are nearly over. The spring crop of Mignonette is now good. Fewer nurserymen are growing Lobelia this season, and consequently its value is higher. Other subjects include Marguerites, Zonal and Ivy-leaved Pelargoniums, Spiræas, Roses, Ericas—including E. Cavendishii, E. perspicua erecta, E. ventricosa magnifica, &c. Foliage plants are well supplied. During the past week the trade in them has been moderately good. *A. H., Covent Garden, Wednesday, May 27, 1908.*

THE WEATHER.

THE WEATHER IN WEST HERTS.

Week ending May 27.

Slight frosts on two nights.—This was on the whole a cool week. On only one day did the temperature exceed the average, and on two nights the exposed thermometer fell slightly below the freezing-point. The ground is now at about a seasonable temperature, both at 1 and 2 feet deep. Small quantities of rain fell on three days, and hail on one of those days. With these exceptions there has been no rain for over 10 days, and consequently there has been no measurable percolation through either of the soil gauges for several days. The sun shone on an average for 5¾ hours a day, which is 20 minutes a day short of the mean duration for the time of year. The winds have been light, and the direction of the air currents variable. The mean amount of moisture in the air at 3 o'clock in the afternoon exceeded a seasonable quantity for that hour by 3 per cent. The first Rose to flower in my garden in the open ground was a variety of Rosa alpina which was out on the 20th, or 10 days later than last year. *E. M., Berkhamsted, May 27, 1908.*

ANSWERS TO CORRESPONDENTS.

*** *Owing to unusual pressure on our space we have to hold over several society reports, including those of the Royal National Tulip Society and the National Horticultural Society of France.*

NAMES OF FRUITS: *W. G. D.* Apple Pinner Seedling.

NAMES OF PLANTS: *E. V. B.* Tellima Heuchera.—*G. S.* We do not undertake to name varieties of Tulips; the coloured bloom is probably Cottage Maid, the white one is probably Tulipa Didieri alba.—*Alpine.* 1, Saxifraga decipiens; 2, Aubrietia deltoidea purpurea; 3, Lithospermum purpureo-cœruleum; 4, Aubrietia tauricola; 5, Saxifraga muscoides; 6, Phlox nivalis.—*J. W.* Maranta bicolor.—*H. W.* Zephyranthes carinata.—*A. K., Dover.* Crinum flaccidum.—*G. D.* Laurelia aromatica.

THE BERLIN IRRIGATION MEADOWS: *Correspondent.* These meadows, or Rieselfelder as they are called, are situated in the neighbourhood of Blankenburg, and several other small towns a few miles north of Berlin. They cover several thousand acres of land. The scheme comprises the sewage disposal of the town. The sewage is pumped into central lakes, from whence it is run out over the whole area through a network of shallow canals, thus forming an excellent dung material for enriching the soil. Owing to the level nature of the land, this work has been somewhat easy, but in some cases the water has to be led underground by pipes before it can find its own level, for the main object is to prevent a rapid flow of water and thus allow the nutritive materials to be absorbed to the best advantage. The system has been in natural operation for a long time, but it was only about 25 years ago that any real effort was made to cultivate the land. An experimental station was established and tests of all kinds carried out under the supervision of competent officers, who spared no effort in the attempt to establish plants for all purposes. Fruits of all kinds, including Apples, Pears, Plums, Cherries, Currants, and Gooseberries, and vegetables and flowers likely to find a ready market were all tried with conspicuous success. Even medicinal plants were given a trial, and the results obtained were sufficient to guarantee a source of income when grown on a larger scale. Reports were published yearly setting out the results of the various experiments, and it was soon realised that from an agricultural and horticultural point of view the fields were of exceptional value. The area is now largely sub-let to various tenants, who make use of it to the best advantage. The largest area is devoted to vegetables, which grow to quite an unusual size, but are, according to popular opinion, somewhat lacking in flavour. This is to be explained by the nature of the soil, for the plants stand in almost pure dung, in many cases with their roots practically in water. Cut flowers form a large source of income, bulbous plants, Chrysanthemums, Dahlias, Pentstemons, Roses, and other plants, bloom well and find a ready sale. As stated in the note published in our issue for January 25, the fruit trees are mostly planted by the sides of the service roads, of which there are an enormous number. Apples particularly revel in the nourishment that they find here, and last year afforded a profit half as much again as in previous years. Corn of various kinds is also cultivated and the results are very successful, whilst Hemp has proved of exceptional value. It must not be thought that the whole of the area is in use. A large part of it is grass land which is at present lying idle, but the development is progressing by leaps and bounds, and bids fair to double its present income in a few years. All reasonable precautions are taken against the spreading of disease and unpleasant smells.

TO DESTROY ANTS: *T. W.* A simple plan is to pour boiling water on their nests, but probably the best remedy is a little bisulphide of carbon or vaporite inserted in the ground when the fumes will cause death to the ants. A preparation known as the Ballikinrain Ant Killer, is efficacious in destroying these pests in plant-houses, but we have no experience of its value on an open lawn. It is POISONOUS. Many thanks for the contribution to the Gardeners' Royal Benevolent Institution.

TULIPS: *A. E., Birmingham.* No Tulip mould has been found on your specimens. The injury is caused by a millipede (Julus pulchellus). It is not necessary to destroy the bulbs; they should be thoroughly dusted with a mixture of flowers of sulphur and quicklime, using half as much of the latter as the former material.

VINE LEAVES: *E. S.* We have been unable to find any parasitic fungus on your vine leaves. The Coleus leaves show two moulds, but neither of them is parasitic. The fact that the damage seems to be confined to the under side of the leaves suggests the attack of some animal pest, but none was seen. Perhaps close observation on the spot might reveal the cause of the mischief, but in the meantime we still have the matter under investigation to determine whether there may be a bacterial origin for the spotting.

WINDMILL PUMPS: *T. E. B.* Write to a firm of horticultural sundriesmen and they will obtain them for you.

WOODLICE: *Constant Reader.* These may be trapped by placing pieces of some vegetable such as Carrot, Turnip, Potato, &c., in their haunts. The baits may be poisoned by soaking them in Paris Green or white arsenic if desired. Steiner's "Vermin Paste" has also been found useful in destroying these pests. Mix the poison with barley meal or middlings and put the mixture on pieces of glass, wood or tin, and place in their haunts.

THE TRADESCANTS.

ONE of the glories of my few square yards of back garden is a fine patch of double purple Virginian Spider-wort, otherwise Tradescantia. It brings to mind two interesting personalities whose names, though perhaps not writ large on the pages of general history, are of special interest to flower lovers. These are the two John Tradescants, father and son. Their names live for us in their beautiful American plant, which we call Tradescantia.

In the famous Ashmolean Museum at Oxford there is a half-length portrait of the younger Tradescant, which represents him leaning on a spade—the implement of his craft. For, as the inscription on their tomb in Lambeth Churchyard states, they were "both gardeners to the Rose and Lily Queen." This was Queen Henrietta Maria, wife of Charles I., and the two Tradescants were both Royal gardeners in the reign of this monarch. One or other of them also laid out grounds for the Duke of Buckingham. Both the Tradescants were much more than gardeners. The inscription on the tomb speaks of three John Tradescants, "grandsire, father, son." The last-mentioned died young, but the elder two, as the inscription goes on to say, "Lived till they had travelled Art and Nature through." They were, in fact, botanists, travellers and collectors. Their house became known in consequence as "Tradescant's Ark." Herrick, in his *Hesperides*, alludes to "Tradescant's curious shells." He also writes, taking strange liberties with the spelling of the name:—

"Thus John Tradeskin starves our greedy eyes
By boxing up his new-found rarities."

One wonders if by any chance the name *Trade skin* is intended for a sort of pun on the eager collecter of skins, &c. Quoting again from the inscription on the tomb, it was a choice collection "Of what is rare in land, in sea, in air. . . A world of wonders in one closet shut." It is said, by the way, to have possessed two feathers of the "Phœnix tayle," a claw of the "bird Roc," and a "Dodad" from Mauritius. Izaak Walton quotes the Tradescant collection in justification of some of the mendacious tales with which he has been beguiling his readers. He has been discoursing, for example, of the river in Epirus which puts out a lighted torch and kindles one not lighted, of the Arabian river which dyes vermilion the wool of all the sheep that drink of it, of the merry river that dances at the sound of music and ceases when the music stops, and others. To assist his readers in swallowing these romances, he says:

"I know, we islanders are averse to the belief of these wonders; but, there be so many strange creatures to be now seen collected by *John Tradescant*, and others added by my friend Elias Ashmole, Esq., who now keeps them carefully and methodically at his house near to *Lambeth*, near London, as may get some belief of some of the other wonders I mentioned."

As here indicated, the contents of the Tradescant ark came into the possession of Elias Ashmole, who added to it, and kept it in a sort of private museum in his house. He left it to the University of Oxford, where it is now housed. It is known as the Ashmolean Museum, though possibly the greater number of specimens were collected by the Tradescants.

The elder John Tradescant established the first Physic Garden, or, as we should now call it, Botanical Garden, in this country. The younger Tradescant travelled much, collecting specimens for this garden. In America he came across a pretty little blue flower with broad, grassy leaves. It is now known as the Virginian Spider-wort. It used to be called Ephemerum Virginianum. When Ruppius published, in 1718, his *Flora Jenensis* he called it Tradescantia. Linnæus adopted the name, and so it obtained the impress of authority.

According to Loudon the younger Tradescant also introduced the Lilac, Acacia and Occidental plant.

The inscription on the tomb ends appropriately, saying that the two Tradescants,

"Transplanted now themselves sleep here; and when
Angels shall with their trumpets waken men
And fire shall purge the world, these hence shall rise
And change this garden for a paradise."

—*G. W. B.*

THE BERLIN BOTANICAL GARDEN.

(Concluded from page 342.)

Considering that the furnishing of the garden was not begun until five years ago, the extent and condition of the collections generally is highly creditable to all concerned. The work of bringing the plants from the old garden at Schonberg was only finished at the end of last year.

In addition to the garden, there is also a large, imposing building containing the herbarium specimens, library, and the museum collections. The State horticultural school adjoining, but independent of the gardens, is another important institution, which takes full advantage of the teaching facilities provided in the Botanic Garden.

The staff consists of a director (Dr. Engler), an assistant director (Dr. Urban), and various botanists. The executive staff is headed by Mr. Ledien, recently appointed curator in succession to Mr. Perring, and previously curator of the Botanic Garden, Dresden. His principal assistant is Mr. Peters, whose special charge is the outdoor departments. There are two principal foremen, Mr. Behnick, late of Cambridge and Kew, and Mr. Vorwerk. Under these there are 23 sub-foremen, each of whom has charge of a department. These are all experienced gardeners, their ages ranging from 22 to 30, and form the permanent garden staff; they are all housed in the gardens, and their wages are about £5 a month. Under the sub-foremen are the temporary garden assistants, who are engaged in spring for a period of about six months. This temporary help in summer is occasioned by the amount of outdoor work during hot weather, while in winter practically no work is possible owing to the frost. Their wages are 18s. or 19s. a week; from 25 to 30 are employed for the six months, about 10 of them being kept on in winter. Sunday duty is paid for at the ordinary rate. These men may be said to fill the place of journeyman gardeners under the English arrangement. There are no labourers. In addition to these, there are the improver gardeners, mostly youths of from 17 to 20. They are engaged for a year, but there is no hard-and-fast rule. They also perform Sunday duty at the same rate of pay.

The working hours for gardeners are from 6 to 6, with half an hour for breakfast, an hour for dinner, and half an hour for tea. In winter, the hours are from 7 to 4.30, with the same time for meals, excepting tea. The arrangements for providing food for the garden staff are quite exemplary, a spacious, well-furnished canteen, situated inside the garden, with a competent cook and a staff of servants, being provided by the authorities, and the food supplied is not only of good quality and well cooked and served, but it is also cheaper than it could be obtained elsewhere. This canteen is open all day, and food may be obtained in it until quite a late hour at night. Compared with the cost of living for gardeners employed near London, say, for instance, at Kew, the cost to the gardeners at Dahlem is about the same.

A mutual improvement society, no doubt a copy of that at Kew, holds fortnightly meetings in a room provided in the gardens. The meetings are well attended by the gardeners and the papers read are of a superior quality. There is also a reading room or library, but as the books are lent out to the gardeners the reading is generally done at home. The conditions of employment in Germany are so different from those in England that comparisons cannot easily be made. Comparing the hours, wages, and other conditions for gardeners employed in the Dahlem gardens with those of gardeners generally in this part of Germany, the Dahlem conditions are not satisfactory. Wages paid in nurseries are higher. *J. G. W.*

ORCHID NOTES AND GLEANINGS.

CATASETUM DISCOLOR WITH MALE AND FEMALE FLOWERS.

A STOUT inflorescence of Catasetum discolor, bearing three female flowers on one side and three male flowers on the other, is sent by Mr. G. Reynolds, gardener to Leopold de Rothschild, Esq., Gunnersbury Park, Acton, who states that another spike, bearing male flowers only, was also produced. On the inflorescence sent the male flowers are greenish, changing to yellow, the shallow galeate labellum being furnished with purplish filaments, arranged moustache-like on either side. The female flowers are about 2 inches in length from the tip of the upper sepal to the base of the deep pot-like fleshy labellum and about twice the size of the male blooms. Both are similar in colour, but in the female flowers the fringe on the sides is reduced to a slightly fringed serration on the margin. In both sets of flowers the labellum is uppermost. Since Catasetum discolor belongs to the section in which the rostellum of the male is not prolonged into antennæ, serving the purpose of bringing about the ejection of the pollinia when they are touched, the columns of both sexes closely resemble each other. In the female, however, it is much the stouter, the ovary also being proportionately thick.

Male and female flowers from the same spike of C. Bungerothii were illustrated in the issue of *Gardeners' Chronicle* for *April 13, 1889*, p. 461.

BELGIAN HORTICULTURE.

M. VUYLSTEKE'S ODONTOGLOSSUMS.

IN the report of the Ghent Show which was published in our issue for May 2 last, particulars were given of a remarkable exhibit of blotched Odontoglossums shown by M. Vuylsteke, of Loochristy, near Ghent. We have now the opportunity of illustrating three of the novelties then exhibited, the illustrations being reproductions from photographs. The most remarkable is Odontoglossum maculatissimum (see fig. 164), which is a cross between O. maculatum and O. ardentissimum. The sepals of this fine hybrid are wholly of a bronzy-claret colour, the petals being heavily blotched with the same colour on the inner halves, and cream-white on the outer. The broad lip is whitish with a large bronzy-red blotch and some pink veining. The plant exhibited had a spike bearing nine large flowers.

O. egregium var. Mme. Jules Hye de Crom is almost entirely of a magnificent shade of bronzy-claret, with white margins and tips to the segments. The attractiveness of the flower is due in a great measure to the brilliant sheen which pervades the surface of the colouring.

At fig. 166 is shown one of M. Vuylsteke's magnificent varieties of O. ardentissimum, named in this case after Mme. Vuylsteke. Those who availed themselves of the opportunity of driving out to Loochristy and of inspecting for themselves M. Vulysteke's collections in cultivation, saw numerous varieties of O. ardentissimum resembling in more or less degree the variety which we illustrate, varying, however, in detail, in form, size, and colour.

The whole collection of Odontoglossums in M. Vuylsteke's establishment present such an appearance of high culture as could never be surpassed. The plants are cultivated in low span-roofed houses, and at the time of our visit the glass work of the houses was wholly covered with wooden lath shading, showing that the amount of sunlight in this part of Belgium is greater than in England at the same period, for there was no direct sunshine at the time. There are water tanks under the stages, generally the whole length of the house, as in many cases in England, and the ventilators are all covered with wasp and bee-proof wire netting, to exclude anything that would interfere with the pollination of plants it is wished to cross.

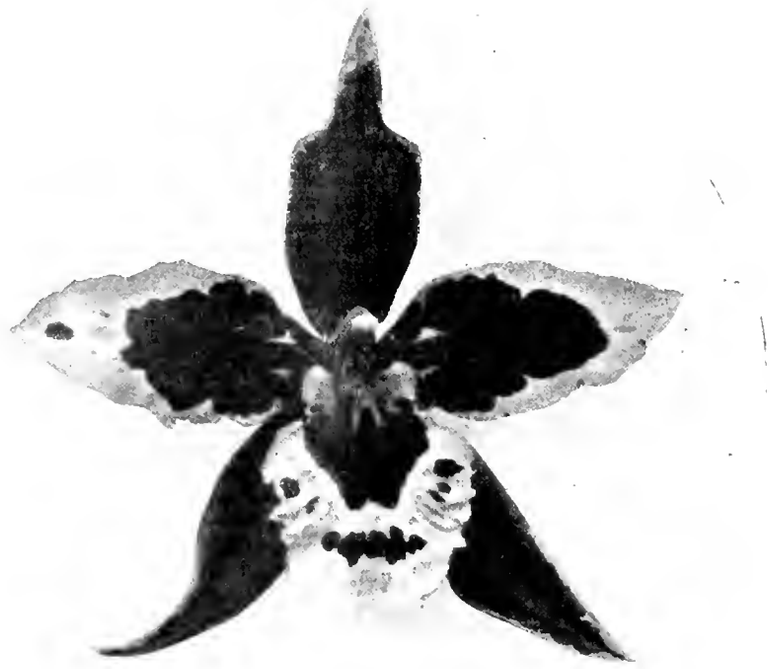

FIG. 164.—ODONTOGLOSSUM × MACULATISSIMUM.

Perfect cleanliness is apparent everywhere, and every plant appears as if it were a selected one rather than a member of a community equal in most respects to itself. In reply to a question, M. Vuylsteke, junr., assured us that no feeding is attempted, the word "feeding" in this case being applied to the giving of manures of any kind. We repeatedly saw specimens showing for bloom in their second year of growth, and were informed that the earliest time that M. Vuylsteke has yet been able to flower an Odontoglossum from seed is 18 months. It is difficult to convey a perfect idea of the strength and floriferousness of many of these Odontoglossum hybrids, but it may be stated that in one instance Odontoglossum Rolfeæ bore 70 fine flowers. In another case a variety of O. ardentissimum had an inflorescence which bore 21 flowers. Another Odontoglossum hybrid, growing in a 5-inch pot, had three spikes bearing together 48 flowers, the pseudo-bulbs being quite remarkable for their size. It was extremely interesting to inspect the various crosses between Odontoglossum cirrhosum and O. ardentissimum. They varied from flowers having white narrow petals, very similar in form to those of Odontoglossum cirrhosum, to others which exhibited the best form of O. ardentissimum, and in colour from pure white to such blotched forms as the one illustrated at fig. 166. It is evident that many surprises are yet to come from Loochristy.

FIG. 165.—ODONTOGLOSSUM EGREGIUM "MADAME JULES HYE DE CROM."

THE ROSARY.

WORK IN THE ROSE GARDEN IN JUNE.

THE inclement weather of April severely affected the Roses in the open garden, and especially those of the Tea and Noisette sections. The milder weather of May has enabled the bushes generally to recover from their injury, but should the shoots be badly damaged it will be advisable to prune them to low-seated buds and trust to a development of secondary growths, which can be aided by a surface mulching of manure and doses of liquid stimulants when growth has become active. The shoots on the standard Briars will now need attention. It will be apparent by the middle of this month which shoots are the best to retain, when three of the firmest and strongest growths near the top of the stock and at opposite angles should be selected, the remaining lower ones being cut clean away. Standard Briars that were budded but failed last year usually develop strong growths early in the second year. These will be quite a month in advance of the autumn-planted Briars and therefore valuable for early budding, using buds taken from well-ripened scions from plants grown

FIG. 166.—ODONTOGLOSSUM × ARDENTISSIMUM "MADAME VUYLSTEKE."

under glass or from grafted plants that have been recently placed outside. Amongst varieties of the Teas and hybrid Teas of special merit are Lady Roberts, Souvenir de Pierre Notting, Mrs. Sharman Crawford, Liberty, Golden Gate, Frau Karl Druschki, and Kaiserin Augusta Victoria. The general budding season will be late this year, and will not be at its height much before July, as before that time no great quantity of either scions or stocks will be available, but in all cases to secure success the bark should open freely and the scions slip out easily from the inner wood. If these conditions in stock and scion do not freely reciprocate, the operation had better be deferred until rain falls. If only a limited quantity of stocks has to be dealt with, I have found a copious soaking of water given to the roots and repeated, will, in a short time, cause the sap to rise, when the work can be proceeded with. The work of securing the buds, the staking and elimination of all wild growths from budded Roses should be completed by the end of June. If bushy heads are required, the maiden bud should not be allowed to flower, but should be pinched when 3 inches or 4 inches long. If the blooms are required for exhibition purposes, the best buds for selection are often found amongst the cluster of the first growth. In this case the first growth from the bud must be left alone and not stopped back. The Rose grower will, in seasons like this, have some difficulty in judging what to expect in the way of blooms by a certain date, and in order to be prepared for contingencies he should have reserve duplicate plants of those varieties he intends to exhibit. The largest growers usually depend on their maiden plants, but these are often only available for the later shows. For early exhibitions the best early kinds should be selected, and to obtain perfect blooms they must be disbudded quite three-fourths or even more, according to the variety. This is a matter entirely for the discretion of the grower. From the time the bud develops, the plant should be given plenty of liquid manure, diluted and alternated at intervals of about a week with the following ingredients in the proportion of 4 ozs. to 4 gallons of water, viz.: 2½ ozs. superphosphate, ½ oz. sulphate of ammonia, ½ oz. nitrate of soda, and ¾ oz. sulphate of potash. The above may be applied either in solution or as a dressing during moist weather and well raked in. If given as a solid it should be sprinkled about the surface of the ground, using equal proportions on each square yard. The above can be used until or before the flowers are expanded, after which it should be withheld. The protection of the blooms during stormy weather or from the scorching rays of the sun is necessary. Secure all plants of standard and dwarf Roses by staking and tieing the shoots; also guard against insect pests and mildew early in the season, as it is much more difficult to combat them later on. A solution of soft soap, quassia chips, or tobacco well steeped in hot water and applied during the evening and washed off next morning with clear water will usually be found effective remedies. The Dutch hoe is the best tool for destroying weeds, and this can be usefully employed between the rows of seedling Briars and amongst all planted-out Roses. The use of the hoe aerates the ground and destroys all small weeds.

All Rose beds in the open should be examined for suckers springing from the roots or stems of plants, and they must be promptly removed.

Cuttings of Roses inserted in the open during October, unless planted due north, must be shaded from strong sunshine, for although a few of them may be rooted, this precaution is necessary for the safety of the others, as until root action is established the solar heat will often cause the top growths to droop and die.

Pot Roses of all descriptions are now best placed on ashes, or plunged outside, in order to give them sufficient rest to recuperate before being brought inside again. During the autumn abundant ventilation both day and night should be given to all Roses planted under glass, and where possible it is much the best to remove the lights altogether during the summer months to thoroughly mature the wood. Well ply the garden engine amongst the plants to thoroughly cleanse them. Roses on their own roots in pots plunged under frames and that have had an abundance of ventilation can now be well vaporised before removing the ashes altogether; any that require repotting should be seen to at once. The plants should be set out far apart on the bed to allow room for the development of the summer's growth, pinching back all straggling and long shoots to promote a bushy habit. The grafted plants will now be well established outside. Carefully examine for insect pests, stake and tie the plants, and stop them a few joints back, so as to make compact specimens. Weak and unripened wood should be removed or be well cut back from all Roses, as such shoots impair the energies of the plant. The early batch of forced Teas, Noisettes, and climbing Roses now out of doors should be kept dry at their roots for a period of about two months, after which they will show signs of fresh growth, and then the exhausted wood can be cut out. After their rest, if the plants are lightly pruned and top-dressed with some rich material and kept well syringed, a further crop of flowers may be expected during the autumn. As there is now plenty of well-ripened wood, advantage should be taken to put in some cuttings on a half-spent hot-bed according to instructions already given. If due care is taken in the matters of shading, watering, and selection of the cuttings, 90 per cent. of the shoots will form roots. *J. D. G.*

MARKET GARDENING.

NOTES FROM A "FRENCH" GARDEN.

THE planting of Melons has been pushed forward as much as possible. Experienced growers have at this time plants always ready for planting out when required. When Carrots and Cauliflowers are doing well, and the grower thinks that they will be ready for market before June 20, he sows a batch of Melons at this time to replace them, instead of the customary crop of Endive or Celery.

The first batch of Melons is well forward. Some have fruits the size of two fists. The selection of the fruits is the most important detail in their culture. In the earliest batch growers are tempted to choose the first fruits which set, generally close to the main stem. This is only done in the early batches, however, for the further the fruit is from the main stem the better it will be in size and quality, though not so early as those taken closer to the stem. We generally let two or three fruits grow to the size of a tennis ball, to be more certain of their shape before leaving the best only. We give them now a fair proportion of water always in the morning before 9.30. One three-gallon can of water is generally sufficient at one time. The Melons

planted two or three weeks ago are given air freely when weather permits. We do not spread the mats at night except when it is chilly, in order to get the plants as hardy as possible without injuring them or impeding their growth.

The batch of Cauliflowers planted among the Carrots are showing bud. They will require all the water we can give them now. The watering of Cauliflowers before they show bud must be done very carefully, as they are liable to rot off if the water is excessive, and they will show bud too early if kept too dry. The batch of Cauliflowers which was planted among the Lettuces under the lights, and the batch planted directly outside, are both doing well. We have sown a batch which will be planted among the Melons, four per light at the end of June onwards till August. Though we like the Cauliflower "Driancourt" as a good all-round sort; we have sown some "Lenormand" which succeeds well through the summer and becomes an enormous size.

The Endive to follow the Cauliflowers among the Carrots have been through the ground these last four days, and receive plenty of air at the present time.

The Cos Lettuces grown under the cloches have all been sent to market, the third batch was ready as soon as the second was gone. We have another batch ready, grown entirely outside since the end of February. They were the same sorts of plants as those planted under the cloches.

The Celery sown at the beginning of April, to follow the Cauliflowers, are pricked off 3 inches apart on an old manure bed. They will require light but frequent waterings till they are well established in their present quarter. Around Paris, where Leeks have a ready sale, growers sow at the present time, in well-prepared beds, seeds of "Long of Paris." They are planted in July in the beds where Carrots and Cauliflowers were grown, 5 inches apart. This batch will be ready for the market in September if freely watered and well cultivated. *Paul Aquatias, Mayland, May 28.*

FIG. 167.—DIMORPHOTHECA AURANTIACA, WHICH GAINED AN AWARD OF MERIT AT THE TEMPLE SHOW. (See ante, page 358.)

NOTICES OF BOOKS.

* "LONDON PARKS AND GARDENS."

FEW persons who live in London realise the extent of the open spaces which help to relieve the monotony of bricks and mortar, and serve both as lungs to the city and as recreation grounds for its inhabitants. The love of gardening is comparatively a modern one, at least, amongst the majority of the population, and perhaps it is, in part at least, traceable to the ever-growing congestion of the large towns, with their teeming populations. At any rate, it is true that those whose visits to the country are few and far between are not the least appreciative of the beauties of woodland and green fields. Fortunately there are always those who enjoy a fair share of this world's goods, who also realise the attraction of rural surroundings, even in the heart of a town. The words of the old poet

"*Laudaturque domus longos quae prospicit agros*,"

are as true to-day as they were two thousand years ago; but for crowded urban populations, green spaces are not merely a luxury, they have become a necessity. The story of these open spaces within that portion of London which is administered by the London County Council is told by Mrs. Evelyn Cecil in a most delightful volume. Even were the subject itself less interesting than it actually is, the book would be well worth reading. The authoress, who is a well-known lover of gardens, has invested her theme with a charm that springs partly from her own familiarity with the places she is describing, but is also enhanced by the literary skill with which she has brought together so much that is of historical interest. Many of the green oases of London have been places of note in the past, and some of them, as, for example, Hyde Park, have played their part in the stormy scenes of the 17th century. Others, again, like the Chelsea Physic Garden, have remained as monuments to the enlightened views of prominent men; whilst still others bear witness to the intelligent foresight of private or public enterprise. It is not generally recognised that there are many trees and shrubs other than those familiar to everyone, which can be grown successfully even in London, and the list given at the end of the volume deserves to be studied by those whose business it is to lay out or to conserve the open spaces of the metropolis. On the whole, the evergreens are apt to be depressing. Their mantle of grime deprives them of attractiveness, even if it did not also injure their health, and it is seen, on glancing at the list, how Conifers have had to be abandoned in the metropolitan area. Even in the outer suburbs these trees are suffering, and every year, unluckily, their condition grows steadily worse. In former times they flourished in some districts. Thus the four original Cedars of Lebanon in the Physic Garden were objects of interest till they, one after another, succumbed to the attack of the smoke fiend.

The volume contains an excellent bibliography, whilst the illustrations, chiefly in colour, by Lady Victoria Manners, lend additional attractiveness to a well-planned and well-executed work.

* ROSE PESTS.

THERE are so many serious pests common to Roses, that a recent publication upon the subject, entitled *The Enemies of the Rose*, and issued by the National Rose Society, will be a great boon to cultivators, whether or not they are members of the Society. The notes upon the fungus diseases and preventive measures are contributed by Mr. George Massee, V.M.H., F.L.S., and those upon the insects by Mr. Fred. V. Theobald, M.A. The work is illustrated by Miss C. M. Beard. The illustrations include coloured plates of Rose-mildew, Rose-rust or Orange fungus, black spot, Rose-leaf scorch, several species of cockchafer, the slugworm, buff-tip moth, winter moth, vapourer moth, Rose Emphytus (Emphytus cinctus), also species of moth, leaf-miner, frog-hopper, leaf-rolling sawfly, and other pests. Having given the names of the contributors, it is scarcely necessary to say that the directions for combating the various pests and diseases may be thoroughly relied upon. The book is edited by Mr. Edward Mawley, the hon. secretary of the National Rose Society, and may be obtained by non-members of the Society through a member on payment of 2s. 6d.

* *London Parks and Gardens*, by the Hon. Mrs. Evelyn Cecil (Alicia Amherst), with illustrations by Lady Victoria Manners. London: Archibald Constable & Co., Ltd. 1907.

* *The Enemies of the Rose*. By George Massee, V.M.H., F.L.S., and Fred. V. Theobald, M.A. Illustrated by Miss C. M. Beard. Published by the National Rose Society.

*PANSIES AND VIOLETS.

WE have here, as stated by the author on the title page, "a handbook dealing with the cultivation and propagation of the show, fancy, and tufted Pansy or Viola for garden decoration and exhibition; the Violetta or miniature-flowered Pansy, mountain and sweet-scented Violets, including selections of varieties for all sorts of purposes." Pansies and Violets have been favourite garden plants in British gardens for several hundred years, and are more highly valued in the present day than ever, as being the most fragrant and beautiful of plants for the decoration of our gardens. Although the Pansy will succeed in smoky, crowded towns, it is only to be seen at its best in the pure air of the country. The Violet, on the contrary, can only be grown with success in the country, for it dwindles and dies when its cultivation is essayed in the town garden. There are numbers of books dealing with the history and plant lore of the subject, and with the cultivation of Pansies and Violets, but those are chiefly of interest to the specialist than to the owner of small gardens. The author of this work is a practised cultivator and exhibitor of these flowers, well acquainted with the requirements of the small grower, as he proves by the varied information afforded in his book. The editor has personally contributed the chapters on the history and botany of the Pansy and Violet, likewise the list of species of Mountain Violets, together with remarks on the foes of Pansies and Violets. These chapters will be found very interesting and enlightening to the reader. The art of propagation by cuttings in spring and summer is fully described, and pictorial examples of cuttings are given. Autumnal propagation for planting out in the following spring is touched upon, and special advice is given in regard to early propagation in the northern parts of the country where Pansies and Violas succeed best. The remarks on grouping Violas in beds and borders, using them as carpeting for beds of Roses and Carnations, and in window boxes, make informing reading; as do those on soil preparation, manuring, together with those on the summer and winter treatment of the plants. The raising of plants from seed by those who may not be able to purchase named varieties is succinctly described. Violettas, a race that originated by a cross effected by the late Dr. Ch. Stuart, M.D., of Chirnside, Berwickshire, between Viola cornuta and Pansy Blue King, have a chapter to themselves. They are fascinating plants. The culture of Violets in the open air and in cold frames and pots is fully described, and the remarks on varieties are valuable.

NOTES FROM LA MORTOLA.

HIBISCUS VENUSTUS.

THROUGH the kindness of Mr. F. C. Baker, now at the Museo Goldi in Parana, I received some years ago seeds of a Hibiscus from Santiago de las Vegas, in the Island of Cuba. From these seeds we have now two shrubs growing in this garden, which in size and foliage somewhat resemble the old-fashioned Sparmannia africana. They began to flower for the first time at the end of last January. The petals were of a very delicate rose colour, which darkened down towards the centre to the deepest tinge of rose-red. As it was impossible for me to make out to what species our plants belonged, I sent some flowers to the Royal Botanic Garden and Museum in Dahlem. According to them the plant seems to be a rose-coloured variety of H. venustus, Blume.

This species was figured in 1891 in *Bot. Mag.*, t. 7183, with cream-coloured flowers. I have no specimens to compare, but the description seems to agree well with our plant. Certainly if it is not the Hibiscus venustus it is a very close ally. The stems of our plant are now about 2 inches high. The young shoots are green and densely covered with stellate and single glandular hairs. Some of these, especially along the petioles, are stiff and brittle and easily hurt one's hand. The petioles are robust and the lower leaves large and quite similar to those described in the *Botanical Magazine*. The upper ones get gradually smaller. The flowers come singly out of the axils of the highest leaves, about three to six on each shoot. The form of the calyx and epicalyx and, of course, of the whole flower is like the figure and description except for the colour. Besides, the flowers of our plant did not open as much as those shown on the plate, but this may be due to the cold period in which the flowers were produced, although they were very beautiful. It is to be seen whether this new shrub will become a favourite in our gardens, as its flowers are likely to be injured by the frost. But where it can be protected during the cold weather it is certain to do justice to its name "venustus." So far no seeds were produced, but cuttings will certainly strike as easy as of other Hibiscus. *Alwin Berger.*

The Week's Work.

PLANTS UNDER GLASS.

By THOMAS LUNT, Gardener to A. STIRLING, Esq., Keir, Perthshire, N.B.

Lilium speciosum (lancifolium).—This species and its varieties, if grown in pots, are very useful for decorating the conservatory and dwelling-house in the autumn. Bulbs that were started early will now be ready for receiving a top-dressing, partly filling up the space left in the pot when the bulbs were potted up. The top-dressing may be applied at two or three times, as it is seen that the new stems are producing roots from their base. The compost for such a purpose should consist of leaf-mould two parts, loam one part, and sand one part, with a little manure from a spent mushroom bed, mixing these materials well together before using them. When five or six bulbs are cultivated in a 10-inch pot they form good, bushy plants, capable of producing a very fine effect. The shoots should be disposed evenly, and for the purpose of training neat stakes should be placed against each growth. In order to obtain well-balanced growths the pots should be turned round occasionally, in order that each part may receive equal benefit from the sun's rays. When the roots are ramifying in their new soil the plants should be afforded frequent applications of weak liquid manure.

Plumbago rosea.—This plant is a useful subject for supplying a display of flowers during winter and spring. Cuttings should now be inserted in a mixture of loam, leaf-soil and sand, and the pots in which the cuttings are inserted should be placed in a house provided with bottom heat, where they will soon form roots. Place four cuttings in a 4-inch pot, and when they are well rooted, repot them, using receptacles having a diameter of 7 or 8 inches for their flowering stage. The shoots should be pinched in order to induce the formation of side shoots. Old plants should have the soil shaken from their roots and be repotted into some fresh loam. Established plants are suitable for planting in a small border; the shoots may be trained up the rafters of the house, from which the flowering shoots may be allowed to hang down.

Rehmannia angulata.—Seeds of this plant should now be sown in order to produce a batch of plants for next season's flowering. The same methods of seed-sowing may be adopted as was recommended for Cinerarias. Plants that are now at their flowering stage, having had the central flower spike removed when young, have developed a number of side growths and formed bushy plants. A small stake should be placed in the centre of the plant and the growths looped to this rather loosely. When in flower afford the plants an abundance of weak liquid manure.

Richardias.—R. africana and the variety Little Gem, when flowering is over, should be planted in an unheated frame, by which system they will succeed much better than if allowed to remain in the pots all through the summer. Place in the frame some good rich loam, with which has been mixed leaf-soil and sand, also a quantity of well-rooted manure. When planting, allow sufficient space for each plant to receive a full share of air and sunlight. Shake away the old soil from the roots and shorten some of the latter that are extra long. In planting, press the soil firmly about the roots, for this will permit a good ball of soil to be lifted when the plants are removed in the autumn. Afford a copious watering with tepid water and shade the frames, which must be kept closed for a few days after planting. When the plants are actively growing they are much benefited by doses of weak liquid manure, for Richardia is a very gross feeding plant

THE HARDY FRUIT GARDEN.

By F. JORDAN, Gardener to The DOWAGER LADY NUNBURNHOLME, Warter Priory, York-shire.

Freshly-grafted trees.—Successful grafts have made very rapid growth during the past fortnight, and they should be given attention by carefully removing the clay and examining the ties to see that these latter are not injuring the stock or scion. Rebind any that may require it, but make the tie more loose than before. At the same time support the grafts by the use of neat stakes, to prevent them being damaged by wind or other causes. As the graft continues to make more growth, all the young shoots which appear below the point of grafting should be removed. In cases where no union has taken place, it will be advisable to encourage a strong shoot to grow from the base, which may be budded presently, and so prevent failure this season. Examine any old trees that were headed down before grafting, and gradually remove any shoots which appear on the old stocks as soon as the scions have commenced to grow. Spray any grafts that are still alive but dormant, in order to encourage the buds to start into growth before the weather becomes exceedingly hot.

Summer pruning.—The pleasant change to milder weather will cause the shoots of Peach and Nectarine trees to grow very quickly, and disbudding should, therefore, be brought to a close by the removal of all those shoots that will not be required next season. The matter of summer-pruning will soon claim the attention of the cultivator. This operation requires great care and forethought, in order that the effect of the pruning may be to direct the energies of the trees to the formation of fruit buds, and to the development of this season's crop. In order to be successful, the operator should possess a good knowledge of the different kinds of fruit trees. He should know which have the habit of producing their fruit on spurs and which produce them on growths made in the season immediately preceding that of bearing.

Thinning of fruits.—Peaches will now have arrived at a sufficient size that partial thinning may be carried out. In the first place, remove all those fruits that would be likely to suffer damage from the wall or the wires, also any other badly-placed fruits may be removed before they commence to develop their stones or kernels. Very few surplus fruits need be left upon healthy trees until after the stoning process is finished—for they will not be likely to fall during that process. A fair average crop for a healthy tree to develop is one having one fruit to each square foot of space. But in determining the amount of crop, the habit of the particular variety should be taken into consideration, whether the individual fruits are large or small, and, in addition, the condition of the individual tree should be considered. Young and vigorous trees may be allowed to carry more than others, but even in these cases over-cropping is not to be recommended, as it invariably results in bringing about a period of unfruitfulness. Nectarines may be left a little closer than Peaches, say, one fruit to every 10 inches square. Reserve as many of the young shoots on these trees as there is proper room for, remembering, however, that each shoot requires to be fully exposed to light and air, or it will fail to mature. Carefully train in all the shoots it is decided to retain, and be very careful not to injure the young wood by pressing them closely to the nails or by tying them too tightly. Syringe the trees with clear water on all suitable occasions, commencing at the bottom of the tree first. Syringe them also occasionally with the XL-All insecticide, as this is a useful remedy for red spider and other insects. It is essential that the trees should be perfectly clean at the time when the fruits commence to colour, as when this stage is reached syringing will have to be discontinued.

FRUITS UNDER GLASS.

By T. COOMBER, Gardener to LORD LLANGATTOCK, The Hendre, Monmouthshire.

Early Peach trees.—When the trees in the earliest house have been cleared of their fruits, the borders should be tested, and if the soil is found to be dry it should be thoroughly watered, applying diluted liquid manure instead of clear water if the trees appear to be weakly. Replenish the mulching material if this is necessary. Syringe the trees vigorously every day; carefully examine them and cleanly cut away any useless shoots which will be chiefly found amongst those which have carried fruit this year. By giving proper attention to this matter the leaves will afterwards be the better exposed to the sunshine and air, the result being that the shoots and buds will become better matured. Ventilate the house freely by day, and less so during the night. As soon as the shoots have become well hardened, both the back and front ventilators may be left fully open.

Mid-season Peaches.—Houses containing fruits which are now swelling for a second time, or commencing to ripen, should be ventilated freely, and no heat will be required during warm, sunny days, but a little artificial heat may be maintained throughout the night and also during days when the weather is dull or wet. When artificial heat is employed, just a little ventilation should be admitted in order to cause the atmosphere to circulate. Do not allow the roots to suffer from want of moisture, nor neglect to syringe the leaves with soft water. In our own case the spring water is so greatly impregnated with lime that its use, even for a short period, would destroy the good appearance of both the fruit and leaves. Expose each fruit as much as possible to the influence of the sun by tying on one side any leaves that overhang them, and also in cases where it is necessary, by raising the fruits upon smooth pieces of glass. If, however, a few fruits be left on the under sides of the branches, the supply will be lengthened, as these will not ripen quite so quickly. Attend daily to the gatherings of the fruits, doing this in the evening if possible, and being careful not to let the fruits become quite ripe before they are gathered, otherwise they will not only lose something of their flavour, but also be liable to receive injury during the process of gathering, or whilst being packed for transit.

Late Peaches.—Let the shoots upon trees in the latest houses be carefully trained, cutting out any superfluous ones. Delay the final thinning of the fruits until the formation of the stones is well advanced. Syringe the trees each morning and afternoon, and keep the roots liberally supplied with water and manure. If mildew should attack either the leaves or fruits, spray them in the evening with a solution of sulphide of potassium at the strength of one half-ounce dissolved in one gallon of water, or, as an alternative, the trees may be dusted over with flowers of sulphur. The sulphide of potassium is the better remedy, but it will discolour the paint upon the woodwork unless means are taken to protect the paint from the spray. Mildew is sometimes thoughtlessly encouraged by permitting cold draughts, especially when the leaves are young, therefore, do not leave the back and front ventilators widely open at night, especially when there are cold winds. It will, however, be necessary to ventilate the house liberally during the daytime. Aphides may be easily destroyed by the use of the XL-All vaporiser, or by dusting the affected leaves with tobacco powder. Now that the outside borders have become warmed by sunshine, they should be given a dressing with some approved artificial fertiliser, and afterwards be mulched with half-decayed stable manure.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree, Hertfordshire.

Mulching.—The importance of mulching can hardly be overstated. It is necessary on all kinds of soil and in all localities, but is particularly useful during periods of drought, and, when practicable, should be applied immediately after a heavy rainfall. Many cultivators think that the more retentive the soil the less need there is for a mulch, but this is a mistaken idea, as such soil requires a mulch even more than soil that is of a lighter nature, on account of the expansion and contraction which is certain to occur in heavy soils, for the consequent cracking of the ground is extremely detrimental to the young rootlets. By applying a timely surface dressing of suitable material the cracking may be prevented, and there afterwards will be less need for applying water, as the mulch will greatly assist in retaining the moisture the ground already contains. June is generally the best month for applying mulches. For such small-growing crops as Beetroot, Carrots, Onions and similar vegetables, I know of no better material than that obtainable from spent mushroom beds, and if possible it should be finely broken up by passing it through a coarse meshed sieve. Long stable manure is excellent material for placing between the rows of Peas, Beans of all kinds, and Brassica crops, especially Cauliflowers, and for globe Artichokes. When nothing better can be obtained to form a mulch, short grass from the lawn, or even leaf-mould may be applied.

Broad Beans.—Make the final sowing of Broad Windsor in a cool portion of the garden. Plants raised earlier in the season and now flowering should have the points of the growths pinched out immediately a good crop of pods is assured. Should black aphis put in an appearance, syringe the growths with a solution of soft soap or some equally reliable remedy.

Endive.—Make a small sowing of both Batavian and the curled-leaved variety, selecting a somewhat shady position for this crop. Afford the plants plenty of water at the roots, or in the absence of this they will quickly run to flower.

Peas.—The ordinary sowings of Peas are very late this season. The crops may be forwarded by pinching out the points of the leading growths and by applying liberal quantities of liquid manure and clear water at the roots. Continue to make further sowings of such excellent varieties as Autocrat and Masterpiece, both varieties being valuable for yielding supplies late in the autumn. Sow the seeds thinly in trenches, in soil that has been properly prepared by careful cultivation.

Savoys.—It frequently happens that plants raised from seeds sown at the end of May prove very valuable in the following spring, as they are better fitted to survive a severe winter than plants raised earlier in the season. Select seeds of small-growing varieties for the present sowing.

Radishes.—Sow seeds in small quantities at intervals of ten days. A good selection of the variety French Breakfast is still one of the most popular, but there are other kinds distinctly attractive and possessing excellent qualities.

Onions.—Spring-sown plants that were raised under glass and have since been planted out are now established. They require to have the soil made very firm about the roots by means of the fingers. Apply the Dutch hoe frequently, and dress the surface of the soil with soot each week.

Cabbages.—Both white and red varieties which were raised during the spring may be planted out as fast as they become ready for transplantation.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Major C. L. HOLFORD, C.V.O., C.I.E., Westonbirt, Gloucestershire.

Lælia harpophylla.—This is not a strong-growing species, but nevertheless healthy plants will grow freely. These require a long rest after flowering, in order to better prepare them for growth, otherwise the "leads" become irregular and the flowering is likely to be disappointing. The plants grow best in pots filled two-thirds full with a mixture of potsherds and charcoal for drainage, and above this a compost of Sphagnum-moss and Osmunda and Polypodium fibre in equal parts. Care should be taken to fix the plants firmly and elevate them slightly above the rim of the pot, surfacing the compost with Sphagnum-moss. Potting should be done as soon as the buds begin to swell at the base of the crown, and in most cases, if the plants have been cultivated well, the pots will have to be broken, taking care not to injure the roots that cling to them. These plants, owing to their slender habit, thrive best in a moist atmosphere while growing, and they require plenty of water at the roots, but there must be ample drainage to allow the water to pass quickly away, and a shady position should be selected in the cool intermediate house for them.

Mexican Lælias.—L. albida, L. Gouldiana, L. autumnalis, and its variety alba, are all sun-loving plants, which grow best in baskets suspended close to the roof glass of a house where a cool intermediate temperature is maintained. The Mexican Lælias have a great dislike to root disturbance, and, therefore, should not be turned out of their receptacles, unless they have become overgrown. Now that the roots are becoming active, any of the old, decayed material should be picked out, and its place filled with new compost similar to that which I recommended for L. anceps in a former Calendar. During the early stages of growth apply water sparingly to these plants, but when they are fully active increase the supply, and syringe them overhead whenever the weather is favourable. Only a thin shade is necessary, and this should be removed early in the afternoon to allow the temperature to rise under the influence of sun heat. If the house in which these plants are grown is kept light and well ventilated, good, firm pseudo-bulbs will be formed capable of producing strong flower-spikes.

Lælia majalis.—This is a lovely, though somewhat shy-flowering, species. Just now the plants are making growths, but there is little root action, hence, although atmospheric moisture is essential, only a little water should be afforded the roots. The flower-buds appear in the partially-developed growths, and are rapid in development. As soon as these are visible, a slight increase of moisture should be applied to the roots, and after the flowers have faded an abundant supply will be necessary until the pseudo-bulbs are fully developed. If any plants need new rooting material, this should be afforded when new roots are being made from the base of the youngest pseudo-bulbs. They should be given the same position, temperature, and potting as recommended above for the other species.

PUBLIC PARKS AND GARDENS.

By JAMES WHITTON, Superintendent of the Parks and Open Spaces in the City of Glasgow.

Culture of hardy plants (continued).—Daffodils.—Of the many excellent bulbous plants in cultivation, none are more accommodating than the Narcissus. In comparison with some other species it may not present so much variety and brilliance of colouring, but for grace and general usefulness it is unsurpassed. The popularising of the Narcissus is one of the most notable circumstances in modern gardening. Here is a genus containing many species and varieties, which for many generations were looked upon and treated simply as common things by the great majority of gardeners. This is all the more striking from the fact that their elegance and beauty were alluded to in song and story, and gardeners are commonly credited as having a poetic bite. Where is there a finer appreciation of the effects of any flower when seen in mass under picturesque conditions than Wordsworth's classical lines on the Daffodil? They contain food for reflection to those studying our subject. Amongst the enthusiasts who laboured to popularise Narcissi with much success was Peter Barr, V.M.H., a veteran well known to many readers of this journal, who well deserves the title of "Daffodil King" which his friends bestow on him. In the various groups in which Narcissi are arranged there are now too many varieties. The niceties of distinction which a certain class of botanists are credited with in regard to the classification of plants is not a whit more pronounced than those set forth by florists of the exact school when riding their hobby. However useful much of such work may be for exhibition purposes, fine details in form are of no account if the variety does not possess the essential qualities of vigour, good habit and floriferousness along with a shade of colour which will make it effective at a distance. Therefore, the time has come when a more rigid elimination of what are now second-rate sorts should be made. There also might be in the classification of sorts a fuller description as to their suitability for specific purposes, such as for early forcing, the supply of flowers for cutting, garden culture, and what here concerns us chiefly, their value for naturalising in Grass. The fact that all sorts are not equally suitable for each or all of the above purposes is well known to many, but it is not sufficiently known to all cultivators. There are other points which necessitate personal experiment. While in some districts the soil appears to suit almost all sorts, there are others in which they grow strongly, but flower sparingly. There are also sorts which rapidly deteriorate or die out under ordinary garden culture, but which, when planted out in Grass and never disturbed will thrive and increase. Obviously, these are the sorts most valuable for the purpose under consideration. We have had a considerable number of different kinds under observation in Glasgow for some years, and it is somewhat surprising to discover how few have come up to a reasonable standard of excellence for our purpose. Many which proved valuable for cultivation in pots, have dwindled away when planted in rough, grassy sward, or on a stiff, clay soil. Of the many fine new forms, several promise well, but they are far too expensive as yet for naturalising. Without classifying them, the following are suitable and satisfactory sorts—N. Pseudo-Narcissus, scoticus, minor, Telamonius plenus, Golden Spur, Henry Prinz, Countess of Annesley, Horsfieldii, Emperor, Empress, Grandee, incomparabilis, Cynosure, Queen Bess, Stella superba, Sir Watkin (which is the most effective of the group), Barri conspicuus, General Murray, Golden Gem, Duchess of Brabant, Duchess of Westminster, Minnie Hume, Mrs. Langtry, Nelsoni, major, Falstaff, John Bain, poeticus, poeticus ornatus (very effective and free-flowering), and poeticus poetarum. The double forms of N. incomparabilis, Orange and Sulphur Phœnix, and the pale trumpets, also the Jonquils have not been at all satisfactory here. There is no lack of variety of form and colour in the selection I have given, and by their use the flowering season can be prolonged for over two months.

THE FLOWER GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

Staking.—Such plants as Canna, Grevillea robusta, Plumbago capensis, Bougainvillea, and Roudeletia will require to be supported by stakes. These should be of neat appearance and of sufficient strength to prevent the plants from being blown by outside winds. Make the soil firm about the roots of these plants at the time of planting, and afterwards take every care to prevent the roots suffering from drought.

Seedlings.—Many plants that have been raised from seeds sown under glass and were pricked out into unheated frames are now ready for planting. China Asters and Stocks require moderately rich soil. Aster sinensis, affording, as it does, such an infinite diversity of colour and possessing long stems which make the flowers valuable for use in a cut state, should, therefore, be planted freely, and during the process of transplanting care should be taken to preserve as much soil as possible about the roots.

Carpet bedding.—A bed or two of this type serves to add variety, and constitutes a conspicuous feature in the scheme of summer bedding. For such beds the soil should be raised somewhat above the level of the turf, and the surface should be made smooth and quite level before the design is marked out. Suitable plants for the planting of edgings are Herniaria glabra and Sedum. Echeveria and Sempervivum are also useful, and, for providing immediate effect, best of all. If the beds are large, when the ground has been prepared for planting, a stout plank should be raised on blocks placed at either end for the planter to stand upon, so that he will not need to tread upon the soil. The young plants being very tender, care is necessary not to press them too severely; at the same time, the roots should be made sufficiently firm that they will soon be able to establish themselves in the soil. Spray the beds occasionally in the evening when the sun has ceased to shine upon the plants.

Sub-tropical bedding.—There appear to be many more plants suitable for this style of bedding than was the case formerly. They have a stately, almost tropical, appearance, but require to be placed in well-chosen positions, where there is shelter from wind, and, where practicable, a backing of choice trees and shrubs. Such plants include Datura, Ricinus, Nicotiana, Lavatera arborea variegata, Abutilon, and Acacia lophantha.

Dahlia.—Plants raised from seeds, cuttings, or tubers should now be planted in mixed borders or beds which have been prepared for them. Salvia patens makes a good companion for the Dahlia. These plants require rich soil, and, if growing in poor soil, are likely to drop their flowers prematurely.

Border Carnations.—Spread a light mulch over the beds, and place stakes to the plants as growth proceeds. The coil stake is much the best for the purpose. The ordinary stake and matting require so much attention to prevent the inflorescence from receiving damage as growth proceeds.

The Rose maggot.—Keep a sharp look-out for the Rose maggot, and wherever a curled leaf can be seen, pinch it between the finger and thumb, it being impossible to reach the maggots by means of an insecticide.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden W.C.

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations. *The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, JUNE 6—
Soc. Franç. d'Hort. de Londres meet. German Gard. Soc. meet.

MONDAY, JUNE 8—
Bank Holiday. Harpenden Fanciers and Agric. Soc. Sh. United Hort. Ben. & Prov. Soc. Com. meet.

TUESDAY, JUNE 9—
Roy. Hort. Soc. Coms. meet. British Gard. Assoc. Ex. Council meet. Nat. Rose Soc. Com. meet.

THURSDAY, JUNE 11—
Exhibition of Colonial Fruits in the Roy. Hort. Hall, Westminster (2 days).

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich 58·2°.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, June 3* (6 P.M.): Max. 80°, Min. 60°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London *Thursday, June 4* (10 A.M.): Bar. 30·1; Temp. 73°; *Weather*—Bright sunshine.
PROVINCES.—*Wednesday, June 3* (6 P.M.): Max. 72° Cambridge; Min 54° Ireland N.

SALES FOR THE ENSUING WEEK.

WEDNESDAY—
Bedding Plants, Palms, Conifers, Bays, retard Lilies, &c., at 12, by Protheroe & Morris, at 67 & 68, Cheapside, E.C.

FRIDAY—
Choice imported and established Orchids in variety, by Protheroe & Morris, at 67 & 68, Cheapside, E.C., at 12.45.

School Gardening.

The inclusion of garden teaching in the curriculum of rural schools is not, as many appear to suppose, a pure innovation, but it was not until four years ago, when the subject received official recognition, that it acquired any real importance. The work had previously proceeded merely on tentative lines; the head teachers of the schools conducted the teaching entirely in their own way and subject to no expert inspection as is the case at the present time. The natural result of this was that while the elementary instruction in certain points may have been sound, its excellence was conspicuous on the theoretical rather than on the practical side, though this was undoubtedly equally important.

The development, however, has been enormous, as appears from an answer given a short time back in the House of Commons, which is recorded on p. 185 of our issue for March 21, 1908, to the effect that there are now no fewer than 1,138 schools in the country which are receiving grants for garden teaching from the Board of Education. Assuming an average of 12 scholars at each of these schools and as the normal class is 14, this estimate cannot be regarded as excessive—it would appear that there are nearly 14,000 pupils receiving instruction in gardening during the present year. It is probable, however, that the number is still greater owing to the increasing popularity of the subject with managers, teachers, and pupils alike. Thus it may fairly be asserted that this phase of present-day education is of great importance, and should be made to become of value to the scholars and to the country at large.

It is often asked what special advantages will accrue from it in the future life of the boy? Will all these boys become practical gardeners engaged in private service or the market gardens of Great Britain? The answer is that there is not sufficient room in private gardening for such large numbers, and if there were, it can scarcely be affirmed that the teaching which they are now receiving, excellent as it is in many ways, is precisely such as would immediately make them expert cultivators. They would still have to undergo the drudgery of the customary apprenticeship, and it is certain that, keen as is their appreciation for gardening now that it takes them out of school during portions of the week, the enthusiasm of the majority would soon wear out.

In market gardens there will be room for some, but the work is not sufficiently remunerative to encourage even a moiety of the number to follow it as a life occupation. What then is the special advantage of this form of teaching? It is a simple question, but, like many others which relate to educational matters, it is not very easily answered. For the purely utilitarian aspect of educational matters is seldom the one that appeals to those who really understand these questions. The main object of *educational* training is essentially *not* to turn out specialists. Specialism comes later, and in so far as elementary education trenches on the more technical aspect of training, it falls short of its proper function, and, confusing two distinct matters, is likely to end in failure. The principle of "Quick Returns" is a very bad one from the educational standpoint.

Of course children must be induced to take as keen an interest as possible in their work, and this is usually most easily achieved by means of exercises that lead to tangible results. It is this which gives elementary science, as well as such work as gardening, its value as part of the school curriculum, and causes it to appeal so strongly to the minds of so many (though not all) intelligent boys and girls.

However, the severely practical person will never be satisfied with these things, but will insist that some direct good should result from the efforts which are being made. Well, he may rest satisfied so far as gardening is concerned. Small holdings are being extended on every hand, and the boys who have been taught the fundamental principles of practical and theoretical land cultivation will be the ones most likely to make a success of such holdings—at least, they will have a material advantage over the man who has drifted on to the land from the city office without the slightest knowledge of the soil, the principles that underlie the working of it, and how and when it must be cultivated to produce the most profitable returns. The mind of youth is most receptive, and it is unlikely that the principles which have been thoroughly inculcated will ever fade entirely away; the fact that the scholars are dwellers in rural districts where a garden is a necessary adjunct to the dwelling-house and work is constantly proceeding, will serve admirably to keep the earlier teaching always fresh in the mind.

But if the instruction is to be of ultimate good in any direction, it must necessarily be sound to start with, and it may, therefore, be well to consider the manner in which it is now given, and see whether it is possible to improve upon it in any way that will make it more substantially valuable in the future. Broadly speaking, there are only two systems in general use, and they sprang from the opinions of two clever and thoroughly practical gardeners, Mr. John Wright, V.M.H., who has had charge of the work in Surrey from its inception, and the late Mr. Robert Cock, in Staffordshire, these two counties having been pioneers of gardening as applied to teaching in elementary day schools. Much work is now being done in all the different counties, but it is largely based upon the experience that was gained at the outset in Surrey and Staffordshire.

In Surrey, reliance is placed upon the individual plot system in which each scholar is assigned a piece of ground varying in extent from half a rod to a rod, and very occasionally slightly more; in Staffordshire the communal plot is adopted on which all the pupils work together. The former system may fairly be expected to bring forth better individual results, for each boy proves his own merit by the results which he achieves. In the common plot the individuality of the pupil is merged into the whole, and it is difficult, if not impossible, to separate the keen and clever workers from the idlers, of whom there are specimens in every school; the large plot, however, has the advantage of allowing of superior instruction being given as to how an allotment or a cottage garden would be actually cropped and managed, with a view to the production of the utmost amount of vegetables from the area at command. Rotations are not now regarded as of the same importance as they were some years ago, but it is desirable that they should be taught, as in certain circumstances they are imperative, and it is quite evident that these can never be as well and clearly shown on an area of half a rod or a rod as they can on 20 or 30 rods. The balance, might appear to be in favour of the larger plot, but something must be debited against it on the score of loss of individuality, coupled with the fact that the spirit of emulation or competition hardly enters into the matter at all. This is a matter deserving of consideration, as a boy will usually strive much more strenuously and persistently when he sees that his neighbour is getting ahead of him in the appearance of his ground and his plants.

The question arises as to whether it would not be possible to adopt a middle course between these two extremes and so to combine the best points of both. This might mean that each pupil should be provided with a small plot—half a rod would amply suffice in this case, though as a general rule it is rather too small—and that in addition there would have to be one large plot, say of 12 rods, on which the class would work in common. If it were practicable, this system might perhaps be expected to produce the most satisfactory results, for the individuality of the scholars would be retained in its entirety, while the communal

working would be advantageous in conveying instruction as to the actual cultivation of a garden. The larger plot would be cropped just as if it were in the hands of an average allotment holder, and close account would be kept of the approximate value of the vegetables grown to set against the cost of production in manure, seeds, tools, and other appurtenances. The chief objection to the universal adoption of the combined system lies in the fact that it would involve the utilisation of more land. This is indeed a serious point, and one which, in many cases, might prove insurmountable, for it is often difficult to find sufficient space to put down 10 plots of half a rod apiece. Overcome this disability, and the best teaching that it is possible to give in gardening in schools would be easy of accomplishment—at least, as far as vegetable culture is concerned.

There is still another direction in which there is plenty of room for improvement, and although it has been for the most part neglected throughout the entire country, it is of great importance. We refer to fruit culture. The production of fruit in this country is an industry of national importance, and we pride ourselves on being able to grow as fine hardy fruit as any country in the world. And yet, if we look at the fruit trees in the average cottage garden, where vegetables are excellently grown, the probability is that we shall see trees that are sometimes cut—to say pruned would be incorrect in 99 cases out of every 100—they are rarely or never fed, and no thought of cleansing ever enters into the owners' calculations. Here, then, is a direction in which the proper appreciation of principles should produce great results.

The principles of fruit culture are as deserving of attention as are those of vegetable growing in the elementary day school gardens of Great Britain, and no efforts should be spared to make provision for it at every rural school. Here again we encounter the question as to the availability of sufficient land, but it is not to be supposed that this would prove an insurmountable difficulty when once the importance of the matter had been fully grasped. There is, however, another serious obstacle in the way of teaching fruit culture, namely, that the principles on which much of the practice depends are somewhat difficult for young students to appreciate, and also it is not easy to find persons who are properly qualified to explain them. In most rural schools the garden-teaching is done by the head teacher himself, and with the occasional help and assistance of the county superintendent of gardening the results are generally so satisfactory that little or no fault can be found, even by the most captious of critics. But the correct management of fruit trees cannot be taught from books, or by advice given at odd moments when the superintendent is making his periodical rounds. Although a general similarity exists between half-a-dozen Apple or Pear trees, the experienced grower knows that each differs from the other in some respect, and that, to achieve the best results, each must be treated as an individual as well in pruning as in feeding, and all other details of culture, and if the teaching given in fruit culture to the boys is to be of permanent good, then every possible point that can be brought into prominence must have consideration and must be clearly explained. Apart from the questions of space and sound instruction, there will necessarily arise that of expense also, but money is found for subjects that are of far less value in schools than is horticulture, and the necessary purchase money ought to be readily forthcoming.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the committees will take place on Tuesday, June 9. At the afternoon meeting of Fellows a lecture on "Wild Flowers and Wild Shrubs" will be delivered by Sir GEORGE BIRDWOOD, K.C.I.E., C.S.I. A Colonial Fruit Show will be held on June 11 and 12.

THE RECENT TEMPLE SHOW.—As supplementary to the report published in the last issue of the Royal Horticultural Society's exhibition in the Temple Gardens, we now publish illustrations of several of the more important exhibits, including the stove and greenhouse plants of Messrs. JAS. VEITCH & SONS (see fig. 168), the stove foliage plants of Messrs. W. BULL & SONS (see fig. 169), and the outdoor exhibit of Alpine and other plants from Messrs. W. CUTBUSH & SONS (see fig. 171). Dimorphotheca aurantiaca, which gained an Award of Merit, was illustrated and described in these pages, and we now reproduce the illustration at fig. 167, it being desirable that the beauty of this plant should be made known to all. The conditions prevalent at the Temple Show are altogether unfavourable for notetaking, and we therefore feel much indebted to our reporters for the inconveniences they suffer in the discharge of their onerous duties. It is not surprising that a few errors creep in. Messrs. WATKINS & SIMPSON have informed us that the vegetables and salads shown by their firm were not imported, as was stated in our report, but they were grown for the firm by Mr. HARVEY at Evesham on the French system, a system which is described in the articles now appearing in these pages on the subject. Mr. MCKAY, of Messrs. WATKINS & SIMPSON, has done much to introduce the French methods into this country. By an oversight mention was omitted of the excellent exhibit of Tulips contributed by Messrs. ALEX. DICKSON & SONS, LTD., Belfast, for which the firm was awarded a Silver-Gilt Flora Medal. It was this firm who showed the fine new Tulip Duchess of Westminster, that gained an Award of Merit.

INTERNATIONAL BOTANICAL CONGRESS.—It is officially announced that the President of the Organising Committee of the Congress to be held in Brussels in 1910 will be BARON DE MOREAU, the former Minister of Agriculture, and that Dr. E. WILDEMAN will act as the general secretary. Committees are to deal also with the nomenclature of cryptogamic and palæontological botany, subjects that are sorely in need of authoritative treatment.

NOTES FROM THE ROYAL BOTANIC GARDEN, EDINBURGH.—The last published number of this periodical gives a number of interesting historical details concerning the rise and growth of this justly celebrated garden, but the special feature in its pages is the interesting account of the work of WILLIAM MCNAB, who was Principal Gardener from 1849 to 1878. MCNAB obtained his early experience at Kew, and on his removal to Edinburgh soon proved that he had made good use of his earlier training. He was an enthusiastic and a capable man, and he thoroughly justified the recommendation made on his behalf by Sir JOSEPH BANKS to Professor RUTHERFORD in 1810, as the result of which MCNAB removed from Kew to take up his duties in the Edinburgh Garden. A portrait shows him as a man of considerable force of character, albeit the picture, it is suggested, does not sufficiently emphasise the natural austerity of his countenance. Reprints are given, in two appendices, of MCNAB'S works on the *Planting of Evergreen Trees* and the *Management of Cape Heaths*.

TREES AND SHRUBS.—We are glad to see the second part of Vol. II. of *Trees and Shrubs*, edited by Professor C. S. SARGENT. It chiefly contains description and figures of a number of species of Cratægus and Viburnum. The Hawthorns are for the most part new species, and many of them are from Missouri, whilst the Viburnums are principally Chinese species which have previously been described by HEMSLEY and others. A conspectus of the Viburnums of China and Japan forms a feature that can hardly fail to be of value, inasmuch as it not only forms a key to the known species, which have increased considerably in number during the last few years, but it also includes an account of their synonymy. The price is $5 nett, and it is published by Messrs. HOUGHTON, MIFFLIN & Co., Boston and New York.

RAILWAYS IN GERMANY AND THE CULTIVATION OF FRUIT TREES.—We note in the German gardening journals that the railway authorities at Frankfort-on-the-Main intend to afford their employees a course of instruction in the cultivation and care of fruit trees, the same to be given at Giessen. Another course will be given on tree diseases, treatment of wounds, and such like treatment of fruit trees. The purposes of the instruction afforded are the cultivation of the fruit trees planted on the railway embankments, and the formation of new fruit plantations by the railway labourers.

PLANTING OF EMBANKMENTS AND OVERFLOW DRAINS ON RAILWAYS.—The Bavarian Minister of Communications has intimated to the railway and building authorities the desirability of planting railway banks and overflow canal slopes with bushes and trees that afford food for the honey bee, in order to encourage bee-keeping and furnish protection for birds.

THE BOTANICAL MAGAZINE.—The issue for June contains descriptions and illustrations of the following plants:—

PANDANUS HOULLETII, tab. 8197.—This species of the screw Pine, now described by Dr. STAPF, was introduced from Singapore in 1865, and flowered in the Jardin des Plantes in Paris for the first time in 1868. It was a male plant like the Kew specimen, from which the figure now published was drawn. Mr. RIDLEY has described it to be endemic in the southern part of the Malay Peninsula, where it grows in dense forests. The fruit is eatable and possesses a Pineapple-like flavour.

RHODODENDRON MICRANTHUM, tab. 8198.—The habitat of this specis is stated to be from Manchuria in the north to Kansuh in the west and Hupeh in the south, but it is noted by all the collectors as being found only on the very tops of the mountains. Franchet states that in its native habitat the species flowers in June and July. The present description is by Mr. T. F. CHIPP, who describes the plant as a shrub of small dimensions. The leaves are oblanceolate, cuneate at the base, glabrous and pitted above, densely scaly below, 1 to 2 inches long, and three-tenths to half an inch broad. The flowers are produced in terminal many-flowered racemes. The corolla is milky-white. Mr. W. WATSON states that the plant now figured was grown in the garden of J. C. WILLIAMS, Esq., Caerhays Castle, Gorran, Cornwall, and was presented to Kew through Messrs. JAMES VEITCH & SONS, by whom it was introduced into cultivation through their collector, Mr. WILSON. He described it

as a bush from 4 to 8 feet high with white flowers, growing at from 5,500 to 8,000 feet. At the Coombe Wood Nurseries the plant has proved to be very free-flowering, the small plants of it being now covered with flower buds. The plant first flowered at Coombe Wood in May, 1904.

BULBOPHYLLUM FASCINATOR, tab. 8199.—This new Orchid is described by Mr. ROLFE. It is a native of Annan, where it was discovered by Mr. W. MICHOLITZ when collecting for Messrs. SANDER & SONS. Living plants were sent home, one of which flowered at Kew in September, 1907. The species is nearly allied to the species Himalayan B. appendiculatum (Rolfe), but has much larger flowers, with various structural differences. It belongs to a small group characterised by their solitary flower scapes. The flowers are crimson and green.

CHIRITA BARBATA, tab. 8200.—This Gesneraceous species was introduced into commerce as C. hamosa in 1895 by Mr. J. SALLIER, of Neuilly, Seine, France. He obtained the species from the late Professor H. BAILLON, who informed him that it had been introduced by seed from the mountains of India. There are no wild specimens of C. barbata in the Kew Herbarium, and it seems probable that it is a native of one of the French possessions in the East Indies. Mr. WATSON states that Chirita barbata has been cultivated at Kew for the last twelve years, being treated as a biennial and grown along with such plants as Sinningia, Achimenes, &c. Seedlings flower well in the following spring. C. barbata is, however, described as being less beautiful than C. Moonii, from Ceylon, which grows 3 feet high and has purplish flowers 4 inches across, and C. depressa, which has the habit of a Sinningia and long-tubed blue flowers nestling among the fleshy leaves. All the species require stove treatment.

GENISTA GLABRESCENS, tab. 8201.—This species is confined to the Lepontine Alps, in the vicinity of Lake Como, on the borders of Italy and Switzerland, where it grows on mountain sides at high altitudes. Mr. J. HUTCHINSON describes it as forming by itself the sub-section Emeroides (Briquet), characterised by the solitary or geminate axillary flowers. It is a shrub about 3 feet in height, has trifoliate leaves and yellow axillary flowers, produced either solitary or as two together. In a note on its cultivation, Mr. W. J. BEAN states that C. glabrescens is not a newly-discovered plant, but it has only appeared in cultivation during comparatively recent years. It is quite hardy at Kew, and one of the most attractive of the dwarfer Brooms flowering in May and thriving well in a light loamy soil in a position exposed to full sunshine. It is of a close dense habit suitable for the rock garden, the original plant at Kew being after twelve years still not more than 18 inches in height. It can be increased by cuttings dibbled in sandy soil under a cloche during August.

A BOTANIC GARDEN IN EAST JAVA.—We learn from Mr. M. BUYSMAN that he has succeeded in establishing a botanic garden in the hill country of Java, at a height of about 4,000 feet above sea level. The climate is good, except that the daily rainfall during the wet season (November-April) is rather trying. Most tropical plants, and those from warm temperate zones, flourish if they can stand the damp, for the dry season is tempered by the abundance of spring. Mr. BUYSMAN has already a large collection of plants from all parts of the world, and it is of interest to note that he finds the Cornspurry and Chickweed (Spergula arvensis and Stellaria media) troublesome weeds, even under conditions so foreign to their usual conditions of climate. Many plants known as annuals of comparatively lowly stature with us, reach, in this garden, a considerable height, and become perennial. Thus Vicia Faba grows to about 7 feet, and is perennial, as also is the Flax. A large number of medicinal plants are grown, and much may be expected from a systematic study of their "virtues," as many of them are held in high esteem by natives, although their use is not as yet recognised by Europeans.

MR. S. ARNOTT.—Many of our readers will learn with regret that Mr. S. ARNOTT, of Sunnymead, Maxwelltown, Dumfries, sustained a bereavement in the death of his wife on the 30th ult.

THE DROITWICH EXPERIMENTAL GARDEN.—The twelfth annual report on the Worcestershire County Experimental Garden at Droitwich and eighth report on the County Instruction Gardens, by Mr. JAMES UDALE, has recently been issued. It is a record of useful experimental work that has been carried out at Droitwich, principally in connection with the culture of fruits and vegetables. Mr. UDALE has already stated in these columns his experience in regard to the pruning of Apple trees, and we are not surprised therefore to find that the results of the pruned and non-pruned trees, whether Apples or Pears, recorded in the report are in favour of the moderately-pruned trees. The illustrations of fruit trees in blossom and fruit, are of specimens that appear perfect in every respect; particularly may this be said of a bush tree of the Pear Olivier de Serres, which was photographed during the blossoming period in 1907. The experiments of the cropping qualities of varieties of Potatos have, perhaps, a less wide application, and the best manures for Asparagus in soil at Droitwich may not necessarily be the best in another district where the soil is of an opposite character. At the same time, it may be said that at Droitwich the best Asparagus has been obtained after manuring with 1½ tons of soot and 2 tons of lime to the acre, especially as we had occasion last season to remark upon the extraordinary weight and quality of a sample of Asparagus received from this garden. Further experiments deal with the "Finger and Toe" disease in Brussels Sprouts and to other plant diseases and insect pests.

THE MANCHESTER ORCHID SOCIETY.—The annual general meeting of the Manchester and North of England Orchid Society was held on May 14, a large number of the members being present. The report and balance-sheet were both satisfactory. In connection with the various competitions which have been held during the session 1907-1908, the following results were declared by the chairman, viz.:—The "Sander" Challenge Cup offered for Cypripediums was won by H. J. BROMILOW, Esq., Rainhill, Liverpool (gr. Mr. Morgan); the "Thompson" Challenge Cup for general exhibits was won by A. WARBURTON, Esq., Haslingden (gr. Mr. Dalgleish), who was much in advance of other exhibitors in the matter of points. J. MCCARTNEY, Esq., Bolton, was second, and he was also awarded a cup. The "Gows" Cup for Cattleyas and Lælias (species and varieties only) was also won by Mr. A. WARBURTON. The next session, which commences on June 4, should prove of great interest to amateurs throughout the country, as there are no fewer than five distinct competitions, and these are as follow:—Messrs. CHARLESWORTH & Co., Heaton, Bradford, offer a 50-guinea cup to an amateur exhibitor who gains the largest number of points for plants which have not hitherto been dealt with by the Society. The competition is to be repeated in three successive years, a new cup of the same value being given annually. Messrs. SANDER & SONS, St. Albans and Bruges, offer a 50-guinea cup for Cypripediums, which may be won outright by an amateur exhibitor who is successful three times, not necessarily in succession. H. J. BROMILOW, Esq., Rainhill, Liverpool, has offered a valuable cup to the most successful exhibitor of general displays of Orchids at the meetings. Messrs. H. LOW & Co., Enfield, have continued their competition for Cattleyas and Lælias. Z. A. WARD, Esq., Northenden, has offered a cup to the exhibitor gaining the greatest number of points for Odontoglossums. All these competitions are open to amateur members of the Society, and the hon. secretary (Mr. WEATHERS) will be pleased to give any information to intending exhibitors. Several Awards of Merit were made to plants at the meeting, including Cypripedium concolor "Ball's variety," shown by G. S. BALL, Esq.; C. bellatulum "Queen of Spain," C. Edithæ var. splendens, C. Queen of Portugal, these three exhibited by H. J. BROMILOW, Esq.; C. bellatulum var. Hodgkinsonii, shown by Dr. HODGKINSON; Cattleya Schröderæ var. heliotropium and C. Mendelii Vine House var., both shown by A. WARBURTON, Esq.

FLORAL PHOTOGRAPHY.—Now that the summer is approaching, many persons who possess cameras may wish to try their hand at photographing floral subjects, and a few hints may not be unseasonable. In the first place it is better to use slow plates rather than fast ones, and the long-focus lenses are more suitable than the short-focus ones which are commonly used with the popular cameras of the present time. The plate should be rendered sensitive to the yellow and green colours, and such isochromatic plates are found by most people to give better results than any films. A coloured screen should also be used in photographing the flowers. The objects to be photographed should be well lit, and it is hardly necessary to say that they must be in a still atmosphere if long exposures are to be given. One important detail is often forgotten by those who photograph flowers, namely, the desirability of using a small stop, whereby the "depth" of focus is increased, and the blurring of the pictures one so often sees can be obviated. Backgrounds are often not so carefully studied as they should be. If the subjects are light-coloured, perhaps black velvet is as good as anything, but whatever material is chosen, it should be of such a texture as to obtrude itself as little as possible, and a yellow-tinted blanket, if placed somewhat out of focus, will be found a suitable foil for many plants.

STOCKS FOR JAPANESE WEEPING CHERRY.—One of the chief attractions of the lawn in early spring is the Japanese Weeping Cherry, Cerasus japonica rosea plena. Grafted on tall stocks, as it should be, its branches, while vigorous, droop gracefully, and in the earliest of spring days are clothed with a mantle of lovely flowers. As sometimes seen this beautiful Weeper is grafted too low. The stocks should never be lower than 6 feet, and 8 to 10 feet would often suit positions better, as the tree is such a strong grower. The best stock for this Cherry is the common Mazzard, one of those greatly used for stocks for fruiting Cherries. If these stocks are set out and grown on for a year or two and then cut down to the ground in spring, they push up a shoot which will make a height of 6 to 8 feet by autumn, ready for grafting or budding the season following. When budded, care is required to regulate the growth as it is made. The bud is inserted on the side, and unless watched and the shoots pinched off or trained as they grow there will be a one-sided specimen. Better to place two buds, one on the side opposite to the other. *The Florist's Exchange (America).*

THE FRANCO-BRITISH EXHIBITION.—The first Horticultural Show in connection with this exhibition will be held on June 24, 25 and 26, in the exhibition grounds at Shepherd's Bush. A copy of the schedule of prizes has recently reached us. The first three classes are confined to French and British exhibitors without further limitation. In the first class the exhibits are to be of groups of plants in or out of bloom, arranged for effect in spaces measuring 20 feet by 8 feet. In the second class, a group of ornamental foliage plants is asked for under similar conditions, and in the third class a group of Orchids arranged with Ferns or small Palms, and to occupy spaces measuring 20 feet by 5 feet. The prizes offered in all the classes are similar, namely, first prize, Gold Medal and £5; second prize, Silver-Gilt Medal and £3, and third prize, Silver Medal and £2. Class 25 is for French and British exhibitors of fruit. The schedule calls for a collection of eight dishes of fruits which may include two dishes of Grapes, one black and one white, two of Melons, two of Strawberries, two of Peaches or Nectarines, and two of Figs, Plums, or Cherries. The prizes offered in this class are equal to those already mentioned. In the section for vegetables the principal class is one open to French and British exhibitors of collections of vegetables to occupy spaces measuring 20 feet by 5 feet. The first prize in this class will consist of a Gold Medal and £3; second prize, Silver-Gilt Medal and £2, and third prize, Silver Medal and £1. In all, there are 35 classes, including open classes for Roses in pots and as cut flowers, Clematis in pots, and other plants. A considerable portion of the classes being confined to amateur exhibitors. Further particulars can be obtained on application to the Superintendent of Horticultural Shows, Executive Offices, Wood Lane, Shepherd's Bush, London, W.

CARNATIONS ON THE RIVIERA.—The *Revue Horticole* publishes a communication on the pollination and raising of seeds from American and French varieties of Carnations, in which M. VILLIBINOIST states that there exists an establishment in the neighbourhood of Nizza, in which 738 varieties are grown, raised on the place from seeds, besides 400-500 of foreign origin. Many good varieties thus raised are scarcely obtainable by purchase, and the local raisers regard the varieties and the methods of crossing pursued as trade secrets, and yet M. VILLIBINOIST would infer that no artificial pollination is adopted, or but seldom. Mostly such seed is sown which ripens under the primitive protecting arrangements. M. VILLIBINOIST makes use in his crosses of the best American Carnations. Of 288 artificially-pollinated flowers, only 39 set their seeds, and the sowing produced 188 plants. A record is kept of the parentage of each cross, and the colours of the blooms of everything sown. In so far as conclusions can be drawn, it is stated that the influence of the mother plant is the stronger in these pollinated flowers. The colours of the flowers dominated the seedlings of such crosses. Some of the blooms measured from 3½ to 4½ inches in diameter. The value of these seedlings cannot be decided until they have been wintered and observed in regard to their perpetual-flowering character.

COMPULSORY SPRAYING.—It is often urged that our manufacturers are slow to adopt up-to-date methods in their business, and we are afraid the fruit grower and market gardener are equally negligent in this respect, and especially in the matter of spraying. In these days of keen competition it cannot be too strongly urged that the proper grading of produce and its freedom from insect and fungus pests are factors of the highest importance in securing the best market returns. That certain growers do observe the conditions is known, and their consignments are always readily disposed of at the best prices, because the purchaser knows that the sample is good throughout and can be relied upon. In the matter of spraying the work must be done systematically, for it is very little use if a fruit grower goes to all the trouble and expense of cleaning his trees and Orchids, if his neighbour neglects to take the same precautions, for the dirty plantation will soon infest that belonging to the more progressive neighbour. This matter is better regulated in Oregon, America, where, according to the *National Nurseryman*, if a grower fails to spray for San José scale, the authorities do it for him and tax him for the work.

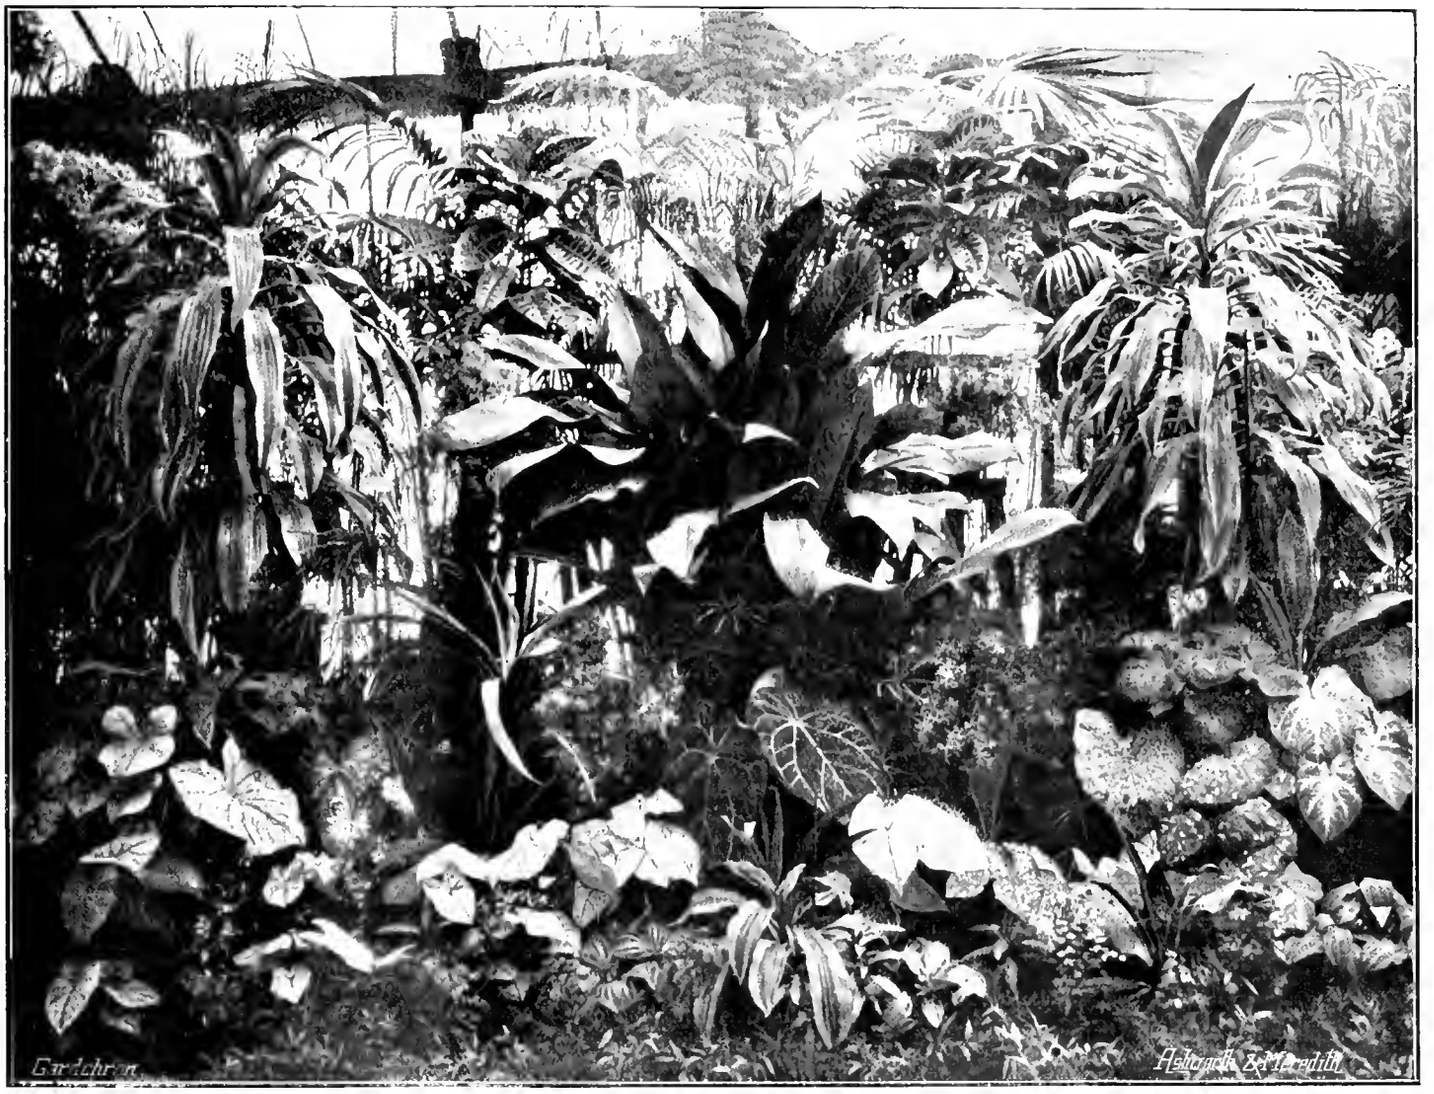

FIG. 169.—MESSRS. W. BULL AND SONS' EXHIBIT OF FINE FOLIAGE PLANTS AT THE TEMPLE SHOW. (See ante, p. 353.)

DISTRIBUTION OF ECONOMIC PLANTS.—Kew has long been engaged in the important work of distributing plants of economic value from one part of the Empire to another, and has in this manner been the pioneer of many industries in the various Colonies, and especially in the newer ones. This important work is very little known to persons other than those connected with the gardens, but in its far-reaching effects it is perhaps the most valuable of all the work that is done at our national garden, and not only does Kew provide the plants but also the young gardener to instruct the natives in their proper culture. Of recent years many of these distant parts of the Empire possess a botanical and experimental station of their own, and they are not so dependent on the Mother Country for their new plants as formerly, although Kew will always remain as an important distributing centre for new and improved varieties. According to the *West Indian Bulletin*, the various botanical and experiment stations in the West Indies are largely engaged in raising and distributing economic plants for the purpose of extending the areas under cultivation in Sugar Cane, Cacao, Limes, Coffee, Spices, grafted Mangos, budded Oranges, Cocoanuts, Rubber and timber trees. An approximate estimate of the quantity of plants distributed during the year 1906-7 is 544,900. These plants are usually distributed at cost price. The largest number of plants distributed in any one colony was 189,266 at Jamaica. This was followed by 136,652 at Trinidad, and 83,505 at Dominica. In one season, 198 mule cart-loads of seedling and other canes from the areas in Sugar-Cane experiments attached to the botanic station at British Guiana were distributed in that Colony. No greater service could be rendered to the cause of agriculture in these Colonies than by the liberal and systematic distribution of improved varieties of canes, fruit trees, and other economic plants.

Publications Received. — *Index Kewensis*, Supplement III., 1901-1905. (The Clarendon Press.) —*Les Sumacs Vénéneux*, by D. Bois, being a four-page bulletin of the Société Nationale d'Acclimatation de France. M. Bois passes under review the species of Rhus cultivated in French parks and gardens, and describes the value of each as an ornamental plant and its dangerous character regarded as a plant containing poisonous properties.—*British Year-Book of Agriculture and Agricultural Who's Who, 1908-9.* Published by Vinton & Co. Price 5s. nett.—*Reports on the Botanic Station, Agricultural School and Land Settlement Scheme*, St. Vincent, 1906-7. Issued by the Imperial Department of Agriculture for the West Indies.

TAPLOW COURT, BUCKS.

(See Supplementary Illustration and fig. 170.)

TAPLOW COURT is a handsome turreted mansion built in the Elizabethan style of architecture and is surrounded by scenery of the most picturesque description. It is the residence of Lord Desborough, and has long been the seat of noble families, for although the present mansion is comparatively new, it was built in 1855 upon the site of an older building, a white stucco or cement encased mansion. At Taplow Court lived the famous Earl of Orkney, who distinguished himself in the wars conducted by the Duke of Marlborough. Our view in the Supplementary Illustration is taken so as to include the north and west fronts; the carriage drive is situated on the east side, the main entrance to the house being approached past a sweep of lawn, in the centre of which is a statue of one of the English monarchs. There is a broad border to the right of this drive that is planted with ornamental shrubs and flowering subjects, and a wall on which are trained choice flowering plants, including many Roses. If instead of approaching to the house, the visitor were to turn through a gateway in this wall, the path would lead him to a walled-in fruit and vegetable garden, the top portion of which may be seen in the right-hand side of the bottom picture in the Supplement. The first object that attracts attention is a huge, cage-like structure made of wire netting and having top cross-bars over which may be thrown, later, fish-netting, the object being to exclude the birds from the fruit bushes below. These are Gooseberries, which we were informed are a favourite fruit of the owner, who likes to gather and enjoy them straight from the trees. The garden was stocked with its crops of summer vegetables, and the walls around were furnished with fruit trees, including Peaches, Nectarines, Cherries, &c. These were all well furnished with fruits, and the setting has been so bountiful that much thinning has been necessary. Apples were a good crop and Pears moderate, on tall columnar trees lining the walks; Gooseberries are the most disappointing crop, the young fruits having dropped in great quantities. Early crops of Peas and Potatos looked promising, especially the May Queen variety of the latter. Cherries looked remarkably promising, and they are cultivated on a large scale, but all are of the cooking varieties; hence Morello Cherries are found on both north and east walls. It is found impossible to grow the sweet Cherries owing to the presence of numerous mice. The stone fruits were remarkably clean in their growth, and we were informed that this is noticeable this season, blight of all kind being practically absent. Traversing this well-kept kitchen garden is a broad walk, the entrance to which is seen in fig. 170, at the back of the ornamental vase. There are arches at intervals spanning the roadway, and on these are trained Roses of red and yellow varieties alternately. The path is a considerable length, but in order to make it appear longer in perspective the arches nearer the flower garden are considerably larger than those at the end, for they diminish in size as they recede from view. This might be practised with good effect in other small gardens. A broad border furnished with flowering plants of numerous species is on either side of the path, and it also accommodates pyramid-trained trees of Apple and Pear. On leaving this enclosed garden by the gate seen in the bottom of our plate engraving and in fig. 170, the lawns and flower garden proper are reached, and the view at once becomes enchanting. It may be said that Taplow Court would be a beautiful spot were no attempt made at floral adornment, for it is situated on high ground amidst all the lovely scenery for which the River Thames, which flows at its foot, is famed. Around are broad belts of trees, with pretty grass drives winding through and about them, and below is the river tumbling over a weir, with tree-clad eyots and banks clothed with wild flowers. But to return to the flower garden: it will be seen that a bold design has been employed, somewhat formal, perhaps, but well carried out, the limits being confined by dwarf, closely-clipped hedges of Box. These beds are partly planted with permanent subjects, and some are furnished with flowering plants. As we saw them on Monday last they were still occupied by the spring "bedding," and this consists of Myosotis as a groundwork to Tulips. More than 5,000 bulbous plants are required to fill these large beds, and they are disposed in batches of distinct colours, the Myosotis being a pink and a blue variety alternately. Enough remained for us to see what a beautiful effect had been produced. In the summer these beds are filled with the scarlet Henri Jacoby Pelargonium and a silver band of the Flower of Spring variety. Our illustrations show them planted with these Pelargoniums.

The other beds of the design have a mixed assortment of hardy garden plants, with ornamental shrubs of small and compact habit, together with formal-trained specimens of Yew and Holly, whilst the beautiful old vase (see fig. 170) forms a fitting centrepiece to the whole. This vase is a noble specimen of the sculptor's art, and forms one of four. They were presented to one of the Earls of Orkney by Queen Anne in 1705, most probably from the rich grounds of Hampton Court. These urns were scattered about the woods of Taplow Court, but the present owner has placed them in sites more in keeping with their worth. These old statues are not the only objects of historical interest, for on the south side is an ancient, but now disused, burial ground. It contains a perfectly preserved barrow or burial mound, and this was opened, as an inscription relates, on October 15, 1883, by James Rutland, the Parish Clerk, and that the many interesting relics found therein are deposited in the British Museum. Mr. Rutland was the last person to be buried in this beautiful spot, and the curious old cromlech which does duty as his gravestone he had prepared beforehand, and it remains as a testimony to his antiquarian predilections. The view from this spot is very fine and enables one to see a great portion of the neighbouring county of Berkshire; beyond is the broad forest of Windsor, and on clear days the Castle itself is easily discernible. The gardeners' art has added a further charm in borders and beds of flowers and flowering trees and shrubs, but nothing is finer than a broad hedge of the Golden Yew, quite 9 or 10 feet through, and which is now a blaze of gold from the tips of the new growths. This has necessarily to be kept low so that the view is uninterrupted. A little lower down the hill is a pond planted with choice Nymphæas. The ground towards the west front falls towards the River Thames, but it is belted with trees, and there is a broad terrace planted with trees, including a couple of handsome specimens of Cedrus Deodora, some old Mulberries, and a large tree of Cercis siliquastrum, the Judas tree, now covered with its red blossoms. There is an old Cedar that stands as a sentinel to an avenue of these noble trees. It has a girth of about 20 feet and it branches into 10 or more leaders, each sufficient to form a tree of good size. This Cedar avenue has a grass vista, the central part of which is kept closely mown, but the other sward has a wild appearance and is beautified with flowering bulbs. These were, of course, over, but a pretty white flower, which spread in sheets, proved to be our wild Saxifraga granulata. The Cedar drive has an additional interest in that it is being extended beyond its former limits, and many notable personages have planted a tree when staying at Taplow Court. The tree-planters include both the King and Queen, the Duke and Duchess of Connaught, Prince Arthur of Connaught, the Duchess of Saxe-Coburg, and other Royal personages, and many statesmen, &c. From hereabouts a walk leads to a summer-house affording a glimpse from the cliff side of the river below, with the falling waters of the weir and the beautiful Berkshire scenery beyond. There is much else of interest at Taplow Court, but we must conclude with a reference to the plant houses. These are compactly situated in a walled enclosure, the gardener's residence, fruit-room, young gardeners' quarters, &c., forming the boundaries. There is a range of lean-to houses, the central portion being larger than the wings on either side; some well-appointed pits and frames and five modern glasshouses running parallel with each other, the central one being the largest and the two outer the smallest structures. These houses are occupied largely with Carnations of the Princess of Wales variety of the Souvenir de la Malmaison type, Lord Desborough's favourite flower. The central house is utilised as a stove, and it is furnished with the usual subjects. There were noticed several well-flowered plants of Cattleya Mossiæ and other species of this showy Orchid, whilst plants of Calanthe

Veitchii and Cypripediums in variety were in an excellent condition of growth. Melons, Cucumbers, Tomatos, and Strawberries were all fruiting freely, and Vines, Peach and Nectarine trees were also well furnished with fruits. In the lean-to structure referred to a tree of Early Rivers' Nectarine has given 200 excellent fruits this season, but the crop was largely gathered when we saw it. Not the least beautiful object at the present time is the Wistaria-clad cottage of the gardener, Mr. W. Williams, who has had the care of the gardens and grounds at Taplow Court for upwards of a quarter of a century. In addition to the fruit and vegetable garden referred to, there is another similar one not far from the old churchyard, and this is maintained in an equally efficient manner with the rest of the gardens and pleasure grounds.

after year exhibitors' demands increase, and the number of visitors grows apace. How then is that growth to be met and satisfied? Certainly not in the Temple Gardens. You have remarked that even in the much more ample space of the Holland House Park, the exhibits are not presented other than in customary form; that is inevitable there, or probably anywhere, so long as tents of the ordinary type are used, as these admit of little variation on stereotyped methods. Not merely do visitors generally see so little, but exhibitors, who have at great cost furnished splendid collections, find, because of the excessive crowding, that their efforts and exhibits are scarcely noticed. That, of course, is to them material loss, for what other reward have the trade exhibitors—by far the larger number of the whole—but to attract public attention and secure

position, which could be used as a garden-designed show, not unlike that so admirably designed by old John Gibson, then of Battersea Park, for the great Horticultural Exhibition of 1866, the space during the rest of the season being planted and kept as a beautiful pleasure garden. Such an area it should be possible to cover entirely with canvas, and thus create a truly artistic exhibition. However, this is but an ideal, whilst the practical difficulties which stare us in the face are overwhelming. *A Fellow.*

COMPOUNDS (POISONOUS) FOR HORTICULTURAL AND AGRICULTURAL PURPOSES.—The horticultural trade should now bestir themselves and approach their members of Parliament and obtain support for Clause 2 of the Poisons and

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

THE TEMPLE FLOWER SHOW.—For several years horticulturists have had to bewail the limited area of the Temple Gardens, and the severe limitations thus compulsorily enforced on the spaces allowed to exhibitors. The horticultural Press has often voiced this expression of feeling, but to hope for more room on the Embankment is to have a desire for the impossible. When, however, the daily papers voice not so much the feelings of exhibitors, as those of thousands of exhibitors who cannot see the magnificent displays in any comfort, it is evident that the question of providing more room elsewhere is becoming a forcible one, for an increase there, of either exhibits or visitors, on what was seen at the recent show, seems impossible; yet year

patronage. How many have cast their eyes longingly on the large area of Vincent Square, that delightful oasis of green verdure amidst the forest of houses in Westminster, as a place for the great May show. Whether it may be obtainable or not the public does not know. Possibly the R.H.S. Council does. If it could be secured, it would certainly be the best central site for the show in London, and although it would not be possible to create in that area a great artistic show, in any case it would so widely distribute the tents that ample room for a much larger show and for thousands more of visitors could be found. To look for Vincent Square is possibly as useless as crying for a slice from the moon. All the same, looking out upon its large area of greensward makes the horticulturist covet a brief possession of it for a great spring exhibition. The best thing which could happen for the R.H.S. would be the possession of an area of some five or six acres in extent, in a central

Pharmacy Bill when it reaches the House of Commons. The final issue between the Traders in Poisons Society and the Chemists Monopoly is fast approaching, and every effort should be made to secure a victory for fair trade. The Bill has this session passed its second reading in the House of Lords, and Clause 2 (which will make it lawful for nurserymen, florists, and agricultural agents to stock and retail insecticides, weed killers, sheep dips, &c.) has been recommended by a joint committee to go forward. It is anticipated that the Bill will reach the House of Commons, from the House of Lords, within the next few weeks, and it is most important that support for the Bill should be obtained at once by the horticultural trade by writing to their members of Parliament, claiming support of Clause 2, as the chemists are opposing it most strenuously, and canvassing members of Parliament. All information as to the way to go to work can be obtained from Mr.

J. G. Dobbs, solicitor, Worcester (secretary of the Traders in Poisons Society). In the interest of horticulture, and for the convenience of the gardening public, I trust that you will insert this letter in your next issue. *G. H. Richards.*

A GOOD "SPRING" BORDER.—A very charming border of spring flowers at Roath Park, Cardiff, this season was one composed chiefly of Aubrietia Campbellii (deep purple) and a yellow Alyssum forming an irregular edging, backed by large masses of the crimson-coloured Primula japonica, and by Darwin Tulips freely interspersed throughout the border. The bright green foliage of Phlox decussata and other perennials (which, with annual plants, will furnish the border with flowers for the summer) now adds freshness and relief to the showy masses of spring flowers. Primula japonica, carefully moved in early autumn, will succeed well for spring bedding in sites that would prove much too dry as permanent quarters for this moisture-loving plant. *Harold Evans, Llanishen, Cardiff.*

THE FLOWERING OF THE BAMBOO.—I am sending some flowering stems of Bamboo spathiflora. The clumps from which they were cut are growing in the grounds of A. F. Sharman-Crawford, Esq., Lota Lodge, Glanmire, Co. Cork, and at the present time are very striking in appearance with their tassellated stems. The plants in question mostly range between 15 and 20 years of age, but several plants much younger are also flowering; one of these was planted only five years ago, and is isolated from all the others. It is interesting to note that Mr. Fyfe experienced similar trouble with his Arundinaria Simsonsii, which all flowered at the same time (see *Gardeners' Chronicle*, p. 299). This habit of flowering and dying in the Bamboo is a great drawback, because a prominent feature of the grounds may be swept out of existence in one season, but as some varieties are evidently more liable to flower than others, we might in planting choose a greater variety and thus save the loss of tropical beauty if the flowering of one particular sort should take place. It would be interesting to learn the cause of flowering in a variety, especially seeing that this takes place simultaneously in districts so widely apart as southern Ireland and southern England. *A. Pearson, Cork.*

SOCIETIES.

BRITISH GARDENERS' ASSOCIATION.

MAY 27.—The annual meeting of this association was held in the Essex Hall, Essex Street, Strand, on the above date, the second day of the Temple Show, which has been considered to be a convenient date for many members. The attendance of about 100 out of a total membership of over 1,200 scarcely seems to justify the selected day. The main deterrents appeared to be the expense and time required for a journey to London, and a general feeling exists that some improved method of representation is urgently desirable.

Mr. Chas. Foster, of Reading, took the chair at 7 p.m., and after the usual formal business had been transacted moved the adoption of the executive council's report for the past year. He reviewed calmly and hopefully the progress and prospects of the association, commenting on the fact that having obtained a total membership of over 1,200 in about four years was a subject for congratulation. Few societies connected with horticulture had ever made so rapid an advance in such a brief period, and it proved that they had gained the approval of a large number of gardeners. At the previous council meeting no fewer than 78 new members had been elected, a convincing proof that confidence was increasing in the work of the B.G.A. They were trying to show that they were in sympathy both with the employer and the employed, as by improving the quality of the latter they were also benefitting the former. The B.G.A. *Journal* was doing excellent work as a monthly publication, and helping greatly to bring members at a distance more closely in touch with each other. It also aided in extending a knowledge of the objects and methods of the association, and certainly the membership had considerably increased, while subscriptions had been more promptly paid since its establishment. The improved education of gardeners was receiving earnest attention, and a provisional scheme for examinations had been set forth, which it was intended to carry out in such a modified form as further consideration and discussion might render necessary. The chairman referred to the question of a permanent secretary, which he said had been the subject of much thought, and the conclusion was that the present state of the finances would not permit of a departure from the system in operation. The work was being done on a most economical basis. Mr. Foster concluded by urging that a steady, sure progress was much more likely to benefit members and gardeners generally than extreme views or measures that would lead to a disorganisation of the relationship between employers and employed.

Mr. E. F. Hawes seconded the adoption of the report, and reviewed the financial position of the association in a lucid manner. The assets comprised £259 12s. 10d. at the bank, and £1 owing, or a total balance of £260 12s. 10d., against which the liabilities were nil. The total expenses for the past year had been £209 6s. 3d., but this included the cost of the certificate and some charges which were incurred in the previous year. He considered the results highly satisfactory. The report was discussed at some length, and its adoption was opposed by Mr. W. Watson, who stated that, as a member of the publication committee, he was certain the *Journal* contained editorial views with which the committee were not in sympathy. He proceeded to comment on the half-hearted policy of the present executive, but on objection to this being raised by Mr. Witty, Mr. Hawes and other members of the council, who pointed out that, as a member of the council who had attended only one of its meetings, Mr. Watson was not entitled to a hearing. Ultimately the report was carried, only four voting against the motion.

The scrutineers, Messrs. R. Lewis Castle and E. F. Hawes, presented the report of the ballot for members to fill eight vacancies on the executive council, and the following were those who obtained the highest number of votes, namely, Messrs. Chas. Hill (211), Donald Campbell (201), Edward Skelton (198), T. W. Sanders (172), Arthur Lampard (157), Inkerman A. Little (153), W. C. Modral (147), and Chas. Raffill (138). The ratification of the ballot was moved by Mr. Witty, seconded by Mr. Frogbrook, and carried.

The chairman regretted that Mr. E. F. Hawes had resigned the office of treasurer, and thanked him on behalf of the members for the services rendered. Mr. Hawes responded, and proposed as his successor Mr. Thomas Winter, which, upon being duly seconded, was put to the meeting and carried unanimously.

In proposing the re-election of Mr. Weathers as secretary, the chairman referred at some length to the excellent character of the work which had been performed, and the admirable way in which several branches had been organised as a result of the secretary's efforts. The proposition having been seconded was strongly supported by several members. Mr. W. Watson moved as an amendment that a general paid secretary-editor should be appointed on the grounds stated by him in a letter to the chairman, a portion of which had been published in the *Journal*. He claimed that the total annual expenditure under this scheme need not exceed £250, and of this sum £150 would be provided by the subscriptions of the present members, whilst he was confident that an energetic secretary would help forward the movement and increase the income of the association. To allay the feelings of those who hesitated, he proposed a guarantee fund, and offered to stand for £10 towards this. After a little discussion, the chairman asked for a show of hands in favour of "Mr. Little" being appointed general secretary. Mr. Little's name was rejected by a large majority, and Mr. Weathers' re-election was subsequently carried unanimously.

Mr. J. Harrison Dick was appointed one of the auditors in place of Mr. Tinley, who retires according to the rules.

ROYAL NATIONAL TULIP.

MAY 26.—Amongst the numerous horticultural attractions of last week, the southern show of the above Society escaped the notice of many Tulip growers, especially as the fixture was not included in the Royal Horticultural Society's list of arrangements. The exhibition was however, held in the lecture room at the Horticultural Hall, Vincent Square, on Tuesday, May 26, and proved very satisfactory to the small band of enthusiasts who foregathered to contribute their best blooms, and admire those from their rivals. A delightfully varied and brilliant display was provided on stages arranged round the room, and the accommodation sufficed both for the exhibits and the visitors.

The classes for rectified Tulips brought several notable competitors together, Mr. C. W. NEEDHAM,, Kelmscott Hall, Cheshire, the hon. treasurer of the Society, securing first honours with 12 distinct varieties, and Mr. J. W. BENTLEY, Stakehill, Middleton, gained a similar place with six varieties. In both these classes Miss WILLMOTT, Great Warley, Essex, was a conspicuous exhibitor, taking 2nd prize in each case with neat bright blooms. Mr. P. W. PETERS, Farcet House, Cambridge, the hon. secretary, also exhibited well. Classes were also provided for three blooms, and the exhibitors already named, with the addition of the Hon. A. H. T. DE MONTMORENCY, Carrickmines, were the most successful.

The classes for breeder Tulips included a number of handsome flowers of soft, varied and brilliant shades, and the competition was keen. Miss WILLMOTT had the best of six blooms, and was awarded a large Silver Medal as the 1st prize, and this lady took a similar place with the best three breeder blooms.

Single blooms occupied a large proportion of table space, as there were numerous entries in each of the classes, namely, for feathered and flamed-rose varieties, feathered and flamed bizarre, feathered and flamed byblœmen, also for bizarre, byblœmen, and rose breeders. Miss WILLMOTT, with Messrs. NEEDHAM, BENTLEY, PETERS, and HALL won the leading honours.

One section of the show, including five classes, was devoted to growers of fewer than 2,000 English Tulip bulbs, and the exhibits were meritorious throughout. The chief prizes were secured by Messrs. R. W. HALL (Cambridge), J. F. KERR (Southend), the Hon. MONTMORENCY (Carrickmines), LEONARD S. LOAT (Oxford), and H. P. BARTLEET (Shooters Hill).

Garden and Darwin Tulips were also provided for in several classes, Messrs. LOAT and BARTLEET being notable exhibitors, both staging winning collections of varieties that appealed to the non-professional visitor much more than the highly refined flowers of the special florists' classes. Some particularly charming yellow-flowered varieties, such as Parisian Yellow, Primrose Beauty, Leghorn Bonnet, Gesneriana lutea, and Bouton d'Or, were prominent in these exhibits.

It is to be hoped that another year the Society will be more fortunate in its fixture, so that a larger number of visitors may have the pleasure of inspecting these charming flowers in their best condition.

NATIONAL HORTICULTURAL OF FRANCE.

MAY 22-29.—This Society held its annual spring flower show at Paris on these dates in the large greenhouses on the Cours la Reine. A large and varied schedule was provided, there being altogether 370 classes. Among the principal prize-winners were M. ROBERT LEBAUDY, to whom was awarded the grand prize of honour offered by the President of the French Republic; the firm of LACHAUME, who received the large Gold Medal given by the Minister of Agriculture; MM. MARON ET FILS, for Orchids; the MAISON FÉRARD and MM. ROYER, CAUCHOIS, PARENT, BILLARD, BOUCHER, CHANTRIER, ROTHBERG, and others.

Along the promenade leading to the show there was an array of greenhouses, garden pottery, and other garden accessories. Several large exhibits of fruit trees trained in the various forms adopted by the French gardeners formed a notable feature, and of these there was a large display by M. NOMBLOT-BRUNEAU and MM. CROUX ET FILS. Collections of hardy

shrubs and hardy flowers were also staged in beds along the promenade.

In the first large greenhouse there was a brilliant show of Roses, Pelargoniums, and Begonias.

One of the most important of these exhibits was staged by the firm of MM. LEVÊQUE ET FILS in a display of Roses. We noted, among others, grand blooms of Frau Karl Druschki and Mildred Grant, and many of the Polyantha section, including Mme. Norbert Levavasseur (a bright rose), Mrs. Cutbush (pale pink) and Maman Levavasseur (deep pink).

M. GEO. BOUCHER also staged Roses in large numbers, including standard plants in variety, whilst amongst other exhibits we may mention those of M. AD. ROTHBERG, M. DUFRESNE, and M. AUG. NONIN.

A collection of Canna in flower was shown by MM. PIENIS ET LARIGALDIE, another of Azaleas in tubs and pots by M. ROIGER, and a large collection of Iris Kæmpferi by M. TABAR. Carnations in great variety were presented by M. BÉRANEK.

Orchids were staged in two side rooms, small collections being shown by M. C. BÉRANEK, M. A. REGNIER, MM. CH. MARON ET FILS, M. LE SUEUR, and M. ROBT. LEBAUDY, who also contributed several other important items in the show.

Hydrangeas in several cases constituted a prominent feature of the show. M. DESIRE RAMELET set up a large number of the variety Thomas Hogg in front of a background of Japanese Maples. M. ROBT. LEBAUDY also showed Hydrangeas with large massive heads of blooms of blue and pink colours.

Floral compositions were arranged at the end of the first large greenhouse.

Before passing into the corridor which connects the two large greenhouses were Zonal Pelargoniums in large numbers. At Paris the arrangement of these flowers is much different from that adopted at English exhibitions. They are always staged in beds on the ground level, and the varieties are massed according to colour.

Three of the beds were staged by M. E. POIRIER; they formed a brilliant display. The same exhibitor also staged a number of standard plants of Zonal Pelargonium, mostly varieties not known on our side of the Channel, but with flowers of good colours. M. ANDRE CHARMET exhibited a novelty in a pink semi-double variety labelled Dagata. Ville de Gardes, a dwarf, double pink Zonal variety, was staged in large numbers by M. PAUL FERON. M. BARILLET showed fancy Pelargoniums in variety.

As the visitor passed into the corridor the view was most pleasing. On the right and left sides were immense banks of Rhododendrons and Azaleas from several of the best known French growers. In the display exhibited by MM. MOSER ET FILS, of Versailles, were noticed choice plants.

A similar exhibit of equally large dimensions was also staged by the firm of MM. CROUX ET FILS. These were a fine collection, with flowers of almost every shade of colour.

The second greenhouse was as gay with brightly-coloured flowers as that previously described. A large number of beds were filled with varieties of hardy flowers shown by M. FERARD. M. BROCHET staged Clematis, Azaleas and Pæonies in large numbers. Tulips and Anemones came from MM. ANGEL ET FILS, and Pansies from M. FALAISE. A very pretty group of Primula obconica was staged by M. JOBERT MAXIME. Gloxinias were put up by M. RENE GUILLOIS. MM. CAYEUX ET LECLERC showed a handsome bed of Impatiens Oliveri, also Bougainvillea and Kalanchoe. A new double white Anthemis called Perfection was exhibited in quantity by M. AUBERT MAILLE. M. DESSERT staged Pæonies in more than 100 distinct varieties. In a tastefully-arranged bed of hardy plants displayed by MM. THIÉBAUT LEGENDRE, were Funkias, Heucheras, Pyrethrums, Geums, Columbines, Iris, Hemerocallis, Lupins, Saxifrages, Phlox divaricata, and many others. Water Lilies in a series of tanks were staged by M. CH. MOLIN, who also had another exhibit consisting of Tulips, Pæonies, Calla, Iris and Lilacs.

Ornamental foliage plants were set up in excellent style by several exhibitors [one of the best being that contributed by M. CHANTRIER, who showed Codiæums (Crotons)], M. LUCIEN LINDEN, M. LE COMTE HUGO CAHEN, and M. VICTOR LEMOINE.

Two fine groups of Dracænas and other decorative plants were staged by M. EMILE MOREL. MM. CORDONNIER ET FILS staged Crotons in variety.

MM. CAYEUX ET LECLERC had several small exhibits arranged in different places. One was of Oriental Poppies.

Begonias are always a feature at the Paris shows, and there were several important exhibits of these flowers. The best were from M. A. BILLARD, who staged a very effective collection of both single and double-flowering varieties. M. E. CAPPE had a pretty bed of ornamental foliage Begonias with Adiantum Ferns intermingled in an artistic manner. Other exhibitors of Begonias were M. FERARD and M. RENE GUILLOIS. MM. VALLERAND staged plants of Gloxinias, the group being edged with Begonias in variety. Of the Gloire de Lorraine variety, M. ROBT. LEBAUDY made the finest display.

M. GEO. TRUFFAUT had a very artistic display of Roses and Carnations arranged on a small grass lawn.

Special mention may be made of a water garden shown by MM. VILMORIN, ANDRIEUX ET CIE. It consisted of a pretty arrangement of rockwork, over which water trickled into a winding stream beneath. Hardy flowers in large numbers were also staged by the same firm. MM. VILMORIN, ANDRIEUX ET CIE also staged vegetables in great variety. There was a large display of vegetables from the SOCIETE DES JARDINIERS ET HORTICULTEURS.

M. GEO. BOUCHER, who is well known for his culture of Clematis, has some fine plants in variety.

Fruit was well represented for the time of year. The exhibits were arranged in glass cases with sloping fronts, and among the chief exhibits were those from the GRAPPERIES DE SOMAIN, M. ALB. MERCIER, the FORCERIES DE LA SEINE, and the firm of MM. A. CORTONNIER ET FILS.

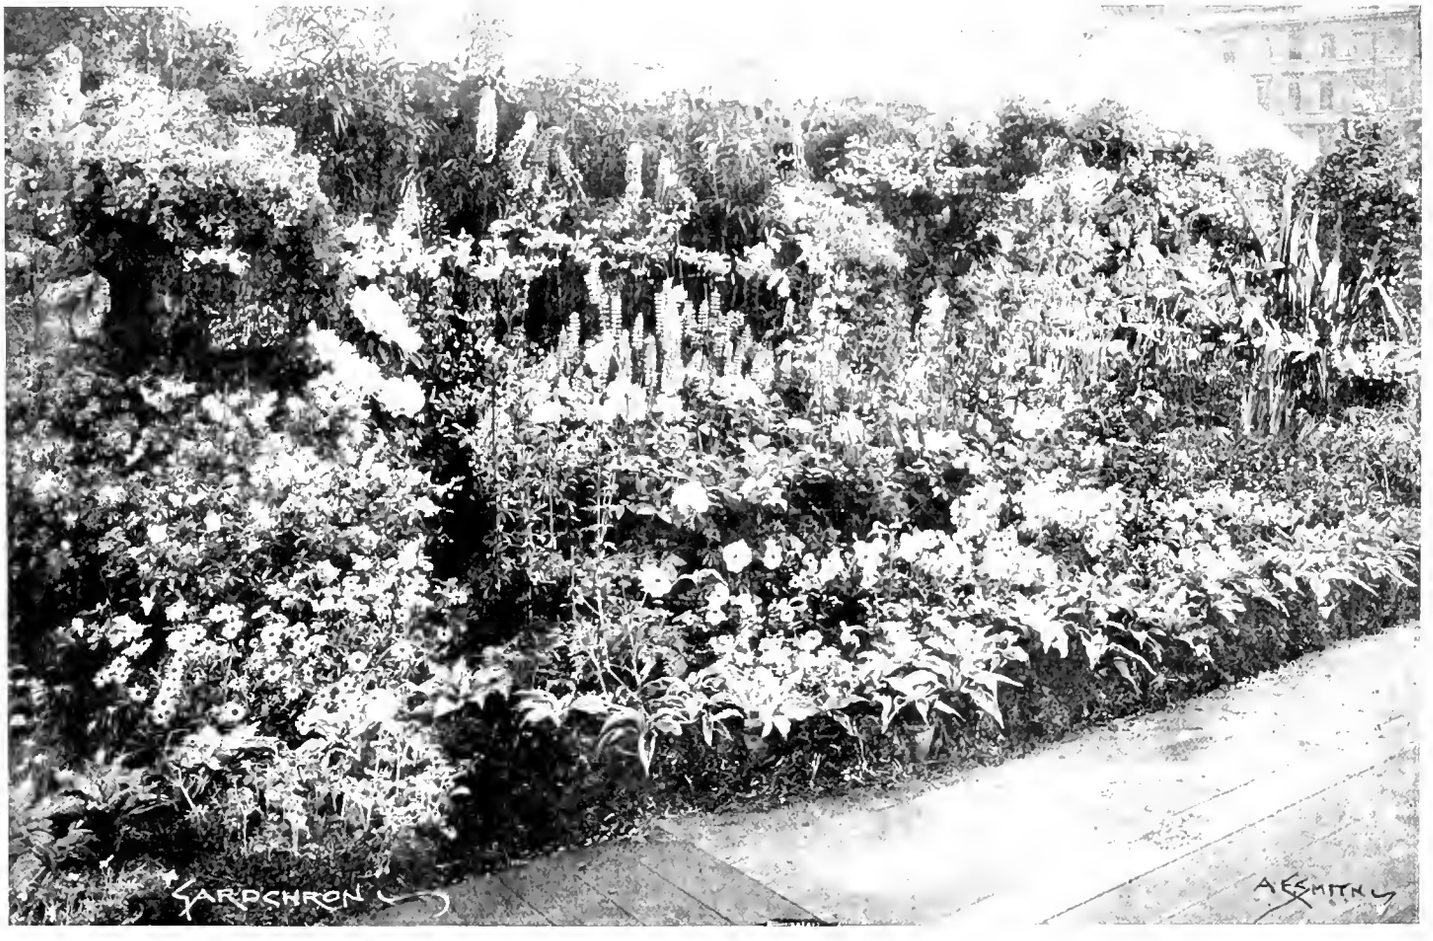

FIG. 171.—MESSRS. W. CUTBUSH AND SONS' OUT-DOOR EXHIBIT AT THE TEMPLE SHOW. (See ante, p. 357.)

DUTCH BULB GROWERS'.

MAY 4, 11.—At meetings which took place on the above dates, the following awards were made by the Narcissus Committee:—

First Class Certificates to Narcissus Alaska, a variety having a broadly-opened, deep yellow trumpet, the perianth being of the same colour; N. van Waveren's Giant, an enormous flower, with deep yellow trumpet and pale sulphur perianth; N. John Pope, with deep yellow trumpet and clear yellow perianth; N. President Weintholt, having a broadly-opened and deep yellow trumpet and yellow perianth; N. Robert Sydenham, a strong grower, with deep yellow trumpet and pale yellow perianth; N. Incomparabilis Winifred, with broad elegant cup and white perianth.

Awards of Merit were given to Narcissus Harry Veitch, a clear yellow trumpet Daffodil in the way of Emperor, but of larger size; N. Cornelia, a self-coloured yellow trumpet Daffodil; N. Theba, a deep yellow trumpet Daffodil of fine form and great substance; N. White Pioneer, having a pure white trumpet, narrow tube-shaped and starry perianth; N. Incomparabilis Louise, pure white perianth and lemon-yellow cup, a drooping flower of medium size; N. Incomparabilis cristata, with peculiar crested crown of yellow colour, perianth cream-white; N. poeticus blanca, pure white, very fine round flower; N. poeticus Glory of Lisse, a fine round flower, with rather large cup; and N. Poeticus Verdii, with large crown, broadly bordered deep orange.

LAW NOTE.

WIRE TENSION GLAZING.

MESSRS. SKINNER, BOARD & CO., horticultural builders and heating engineers, Bristol, have been granted by the Judicial Committee of the Privy Council a prolongation of their patent term in respect to their invention for glazing on the wire tension principle. It was admitted that royalties to the amount of £2,100 had been received in addition to the profits the firm of Skinner, Board & Co. had received in the manufacture of the patent wire tension greenhouses. Mr. Bramall, as a member of the public, urged that the petitioner's accounts showed that a full and reasonable remuneration had been received, and on that ground he opposed the prolongation of the term. Mr. Rowlatt, on behalf of the Crown, pointed out that the invention had not a very wide application, and considering all things, he thought the petitioner had received a very substantial sum during the patent term. He could not oppose on the question of merit, as without doubt there was considerable merit in the invention as applied to greenhouses. Lord Macnaghten, in delivering their lordships' decision, said that the petitioner had received considerable remuneration, but, having regard to the merits of the invention, its utility, and the difficulty the patentee must necessarily have found in bringing the invention to the notice of the public, except by exhibits, their lordships would humbly recommend his Majesty to grant a prolongation of the patent for three years.

ANSWERS TO CORRESPONDENTS.

CHRYSANTHEMUMS, &c.: *T. G. A. O.* Your specimens were insufficient for a proper examination being made to determine the cause of the injury. If you will send better examples, packed in damp moss, we will endeavour to assist you. In hot weather plants soon become dried in the post, unless damp moss or blotting paper is used in their packing. Cotton wool should not be employed; it is absorbent and extracts moisture from the specimens. We hope other correspondents will take note of these remarks.

COLEUS LEAVES DAMAGED: *W. L. D.* The leaves have no disease present, but exhibit injury from some cultural error, which may be due as you suggest to a hot, dry atmosphere through placing them too near the hot-water pipes. As similar plants in a cooler position have exhibited no trace of damage, the cause cannot be attributed to carelessness in watering or general attention.

CUCUMBERS FAILING: *Ashtonian.* The whole trouble has been caused by too much moisture at the roots of the plants. Stir the soil to aerate it, and apply water more cautiously.

EMPLOYMENT AT KEW GARDENS: *W. G.* You can obtain particulars from the Curator of the Gardens. No sleeping accommodation is provided by the authorities for the young gardeners at Kew, but there are numerous lodging-houses outside the gardens where accommodation can be had.

FROGS: *The Japan Seed and Plant Company.* We are unable to give you the names of persons who breed snails or frogs for table use.

FUCHSIA RICCARTONII: *R. B.* This plant is a variety of F. macrostemma, a Chilian species. It was raised by the late John Young when gardener at Riccarton, near Edinburgh, between the years 1830-35, from the variety globosa, which is also a form of F. macrostemma. See letter by the late John Downie in the *Gardeners' Chronicle*, February 20, 1875, p. 245.

GRAPES: *F. T. B.* There does not appear to be any disease in the specimens, therefore the trouble is probably one having to do with the culture afforded the vines.—*C. F. F.* The spots on the Grapes are not due to disease, but are caused by the condensation of moisture on the berries. A mixture consisting of equal quantities of soot and sulphur, sprinkled on the Turnips early in the morning, will check the Turnip fleas, of which you also complain.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. *Correspondents not answered in one issue are requested to be so good as to consult the following numbers*

PLANTS: *Hortus.* 1, Lissochilus Krebsii var. purpuratus; 2, Pulmonaria saccharata; 3, Saxifraga granulata plena; 4, Veronica gentianoides pallida; 5, Tellima grandiflora.—*J. G. D.* Cyphomandra betacea, the Tree Tomato.—*T. B. B. & F. B.* Prunus Padus, the Bird Cherry.—*T. C.* Manettia bicolor.—*W. H. C.* 1, Potentilla rupestris; 2, Barbarea stricta; 3, Equisetum arvense; 4 and 5, Sisymbrium officinale; 6, Nepeta Glechoma; 7, Diplotaxis muralis; 8, probably Œnanthe crocata; 9, Senecio paludosus; 10, Lepidium Draba.—*J. W. & Sons.* Polygala vulgaris.—*Alpine.* 1, Potentilla splendens; 2, Thalictrum aquilegifolium; 3, Dryas octopetala; 4, Saxifraga taygetea; 5, Thymus serpyllum var. lanuginosus.—*Enquirer.* 1, Gaultheria Shallon; 2, Taxodium distichum; 3, Rosa Banksia; 4, Juniperus chinensis; 5, Thuya dolabrata; 6, Clematis montana.—*H. G. L.* 1, Cupressus nootkatensis; 2, Picea Morinda; 3, Sequoia sempervirens; 4, Pinus insignis; 5, Cryptomeria japonica; 6, Thuya dolabrata.—*X. Y. Z.* What miserable specimens! We will do our best. 1, Iberis sempervirens; 2, Sedum acre; 3, Saxifraga cæspitosa; 4, Sedum lydium; 5, Phlox Nelsonii; 6, Aubrietia, variegated var.; 7, Spiræa arguta.—*B. W. W.* 1, Halesia tetraptera; 2, Pinus excelsa; 3, Sequoia sempervirens. 4 Tsuga Mertensiana; 5, Acer platanoides var.—*T. T.* 1, Bulbophyllum auricomum; 2, Coelogyne ochracea; 3, Sarcanthus Williamsonii; 4, Tainia Hookeriana; 5, Oncidium pulchellum; 6, Oncidium tetrapetalum.—*H. J.* Brassia maculata and Ceanothus dentatus.—*Hortus.* Probably an undeveloped Eria acervata.—*W. S.* 1, Ulmus campestris foliis-variegatis; 2, Tilia europæa laciniata, the cut-leaved Lime; 3, Crataegus pyrifolia.—*A. M., Londonderry.* Clianthus puniceus.—*Rev. E. S. M.* Magnolia × Lennei. We cannot undertake the naming of Roses, which should be sent to a Rose nurseryman who can match them in his nursery.

NECTARINES DROPPING: *W. H.* There is no fungus present in the fruits, therefore their dropping is not attributable to disease. It may arise from constitutional weakness in the trees, or be caused through failure at the stoning period. See that the border does not lack lime in some form, the best being old mortar rubbish.

PEACHES DISEASED: *S. B.* The fruits are attacked by the Peach-mildew (Odium sp.). It is difficult to save the young fruits when they are infected with the disease, but the spread of the fungus may be largely stopped by an application of flowers of sulphur, especially if it be applied when first detected. Predisposing causes include dryness at the roots and a damp atmosphere insufficiently heated.

PEAR FAILING TO FRUIT: *Egiob.* The shoot you send is perfectly healthy, and the young fruits are falling apparently because they have not been fertilised. This may be due to a constitutional weakness in the tree, and as other Pear trees on the same wall give excellent crops of fruits, it will be advisable to replace it with another specimen. If you wish to save the tree, which is scarcely worth while as you say it has only produced half-a-dozen fruits in 20 years, try a vigorous root-pruning in the autumn, and apply some old potting soil to the rooting medium.

PEAR LEAVES BLISTERED: *A. L.* The injury is caused by the Pear-leaf blister-mite, Eriophyes piri. The best method of combating this pest is to pick off the diseased leaves before July and burn them. If the work be delayed longer the mites vacate the old leaves, enter the buds, and attack the foliage again the following season.

ROOTS OF CYCAS REVOLUTA: *D. C.* The nodules on the roots you send of the Cycas are not injurious. Nodules are usually present on the roots of Cycas when the plants are healthy. The roots you sent were quite dead, and are evidence of your specimen being in a bad condition. You should turn the plant out of its pot, wash the soil from the roots and stand the stem in a cool, dry place for a month or more, afterwards potting it afresh in the smallest pot that will accommodate the stem, using a mixture of three-parts good turfy loam, one of brick rubbish, and one of sand. Place the plant in a light position in a warm greenhouse and afford very little water until the new leaves are well into growth. The usual cause of failure with Cycas is over-watering, for although most of them are evergreen, they require a resting period, and this is best attained by withholding the water supply at the roots during the winter months, giving only sufficient to prevent shrivelling of the leaves.

ROSE STEMS DECAYED: *W. L.* The damage is done by a fungus, Valsa prunastri, which is probably abundant on some old Rose or Plum tree in your garden, giving the stem a cankered, scabby appearance. This should be discovered and destroyed, as until this is done the spores will continue to infect other Roses in the vicinity. We should be pleased to receive more specimens for further investigation.

SEEDLING PEAS: *A. H. and W. G.* The plants are attacked by the fungus Thielavia vasicola, which causes root rot. This fungus was illustrated in *Gardeners' Chronicle* for June 8, 1907, p. 361. Try weak applications of sulphate of potash to the soil containing the roots.

TOMATO LEAVES INJURED: *T. J. H.* There is no disease present on the foliage you send: the trouble has been caused by scalding from the sun's rays. The plants have been watered when the sun has been shining brightly, with the result that drops of water have acted as lenses and focussed the sun's rays so as to scald the tissue. If it is impossible to maintain drier conditions in the house, spray a very thin coating of whitewash on the glass on the sunny side of the house.

THE DELL, EGHAM.

SEATED in the conservatory, which extends the whole length of the mansion and to which the brightest floral products of his beautiful garden are brought as they appear, Baron Sir H. Schröder delights to talk about the relative merits of the many fine plants which have been acquired by him, and concerning which he is always ready to give many interesting particulars. At the present season, when the outdoor gardens are so beautiful, the need of the extensive blocks of glass-structures at The Dell is not so apparent as in the dull season, for the view from the house of smooth green lawn studded and bounded by arrangements of bright-coloured flowers is a charming one. In the centre of the large expanse is a geometrical garden with spring flowers and Tulips and other flowering bulbs. Around are the beds of Rhododendrons, the finest obtainable, just commencing their great show of flowers; in the distance are giant Cedars, and among them specimens of the rarest Conifers of great beauty. In the side-walks are borders of herbaceous perennials, the spring-flowering species of Primula being very effective; and in every part of the garden neatness prevails, for Mr. H. Ballantine, who has been gardener at The Dell for so many years, co-operated with Baron Schröder in forming the garden, and takes the keenest interest in preserving its reputation as one of the most beautiful and complete in the country.

This collection of Orchids, being one of the oldest and most complete, some of the sections of plants in it indicate how "fashion" in Orchids, as in most other things, continually changes. Here we have a house nearly filled with Vanda suavis, Vanda tricolor, and other Vandas; another partly filled with species of Aërides and Saccolabium. These used to form the chief attraction at flower shows forty years ago, and are still as beautiful as ever, but they are seldom seen in modern collections.

Odontoglossums, and especially the many beautiful forms of O. crispum, tell a different story. From the first they were favourites with Baron Schroder, who bought liberally even before their merits and rare value were fully recognised. In 1885 First-class Certificates were given to O. crispum Schröderianum and O. c. Sanderianum from The Dell collection; the latter is now in flower there, and it is a very handsome form. In 1886 O. crispum apiatum secured a similar award, and is still one of the most beautiful varieties. It reached the highest price of its time, but values have trebled since then.

Odontoglossum Pescatorei Schröderianum and O. P. Veitchianum, two handsomely blotched forms acquired about 1883, and still flourishing at The Dell, afford remarkable instances of the distinctive character of these blotched Odontoglossums, for none has ever been imported since which equals them.

In walking through the cool Odontoglossum houses, many of them producing strong flower-spikes, we noticed the handsome O. crispum Leonard Perfect; O. c. Veitchianum, a very handsomely-marked flower; O. c. Britannia, with a spike of purple-blotched blooms; O. c. Oakfield Sunrise, O. c. Lucianii, O. c. Lindenii, O. c. Mundyanum, O. c. Rex, O. c. Robert McVittie, O. c. G. W. Law-Schofield, O. c. Pittianum, O. c. Doris, O. c. Queen's Birthday, O. c. Haroldianum, which is a very distinct fringed variety, showing some markings as on the labellum on the lower segments; O. c. Magnum Bonum, and many others.

Of other varieties of Odontoglossum in bloom were the superb O. Wilckeanum Schröderianum, which secured a First-class Certificate on May 12; several very handsome forms of O. Andersonianum; O. polyxanthum, O. Hallii xanthodon, a very fine form; the pretty pure white O. Oerstedii with 25 flowers; a very large and distinct form of O. Humeanum with large cream-white lip spotted with brown; O. Horsmanii and O. Chestertonii, two old-time blotched varieties; varieties of O. elegans and O. triumphans.

Also in the cool-houses is a very fine show of scarlet and purple Masdevallias; Cochlioda Noezliana, and Sophronitis grandiflora; and several interesting terrestrial Orchids, a speciman of Orchis hircina bearing a very strong, many-flowered spike of singular flowers; the pretty Cynorchis compacta, which regularly bears many sprays of white flowers, and Stenoglottis longifolia. It is also interesting to note that Disa grandiflora thrives well here, suspended in a cold house near the glass of the roof, although it formerly proved unsatisfactory when grown on the stage. The Cymbidiums are also grown in cool conditions. C. Sanderi (insigne) thrives more vigorously than when grown under warmer conditions. Here, too, is the original specimen of Cymbidium Tracyanum, a nice plant of C. Schröderianum in bloom, and representatives of most of the best varieties.

In the large span-roofed intermediate house some fine varieties of Cattleya Mossiæ, C. Mendelii, and Lælia purpurata are in flower. Of the last-named L. purpurata Schroderiana is the best of the white forms and L. purpurata Lowii the darkest in colour. Cattleya intermedia alba, C. Skinneri, Lælio-Cattleya Schilleriana and some of the hybrid Brasso-Cattleyas and Brasso-Lælias are also in bloom, and suspended from the roof is a complete collection of Lælio-Cattleyas. Mr. Clarke, the foreman in The Dell gardens, called attention to the original plants of most of the earliest Veitchian hybrids, L.-C. Dominiana, L.-C. Canhamiana, L.-C. bella, L.-C. callistoglossa, and others which have been in the collection for a quarter of a century, and which yet hold their own in point of beauty. In these houses were noted a fine specimen of Epidendrum prismatocarpum with many spikes, Epiphronitis Veitchii, Epilælia radico-purpurata, Lissochilus Krebsii, Bulbophyllum Dearei, with six flowers, and B. barbigerum with five sprays of its singular, feather-lipped flowers.

In an intermediate range in several divisions the first division is filled with a quantity of hybrid Cattleyas and Lælias raised at The Dell; the second with a good selection of Cypripediums; the third with large specimens of Cœlogyne cristata varieties; and the fourth with Miltonia vexillaria, flowering very profusely, and including a strong specimen of the rare M. v. Memoria G. D. Owen, with large rose-pink flowers, having a triangular deep crimson mask at the base of the lip and an elongated blotch of the same colour on the bases of the petals. Also in this range were noted a number of healthy little plants of Dendrobium speciosum Hillii, raised from seeds collected in Australia; Cymbidium Devonianum, Dendrobium chrysotoxum, and others in flower.

Facing the entrance to the largest warm house is a fine display of Thunias, the white and rose T. Veitchiana predominating, the tall reed-like stems bearing ten or twelve drooping racemes on each specimen. The white and yellow T. Marshalliana, and the purplish rose T. Bensoniæ are equally effective. A specimen of the yellow Dendrobium clavatum bears 18 fine spikes, and others are also in bloom. In the next division the centre is furnished with scarlet-spathed Anthuriums, and the side stages have a fine lot of Cypripediums in flower. The pretty Dendrobium illustre bears several spikes, some specimens of Cœlogyne Dayana, and the fine Dell variety of it a plentiful supply of long drooping racemes of flowers. The salmon-tinted Cœlogyne tomentosa has many spikes, and of the green and white Cypripedium Lawrenceanum Hyeanum, C. callosum Sanderæ, and their product C. Maudiæ a good show of

flowers is made on many specimens. A house of hybrid Calanthes has a good batch of the best of its class, C. Baron Schröder, raised at The Dell, and the large seed ovaries on one of the specimens tell that it is being used for raising new varieties.

The other plant-houses are most of them full of plants in flower or coloured foliage plants, all well grown; and the extensive ranges of vineries and other fruit houses are in their usual neat condition and promising for good crops.

One house contains a very fine lot of Gloxinias in bloom, the crimson and spotted varieties being especially good; another house is a mass of flowers borne by the many-coloured Schizanthus, white Lilies, scarlet and white Hippeastrums, Rehmannia angulata, &c., and in other houses were a fine lot of Carnations, Giant Mignonette grown to perfection; Lobelia tenuior of a very deep indigo blue; a splendid lot of herbaceous Calceolarias with fine heads of bloom, an excellent display of Caladiums, and on the roof in one house a well-bloomed example of Gardenia Stanleyana with many large, trumpet-shaped whitish flowers blotched with claret colour. *J.*

FIG. 172.—CAMPANULA FRAGILIS: FLOWERS BLUE.

CAMPANULA FRAGILIS.

CAMPANULA FRAGILIS derives its specific name from the ease with which the shoots are broken, and because of this character it is known as the Brittle Harebell. The plant attains to a height of a few inches only, for the shoots are trailing, and, when growing freely, reach a foot or more in length. The growths bear comparatively large flowers of a delicate blue colour. Because of its drooping habit the plant is especially valuable as a basket subject, and, grown in this manner, it is often seen in cottage windows. Propagation may be readily effected by means of cuttings inserted in the spring; the plant may also be divided if great care is exercised in the operation; if not, the reason for the specific name will be at once brought to the mind. The plant is a native of Southern Italy, therefore it is not perfectly hardy unless in very favoured parts of this country. Although the type plant is almost glabrous, there exists a very hairy form known under the name of C. f. hirsuta. Unfortunately for the cultivator, snails have an especial liking for this species of Campanula. A coloured illustration of C. fragilis appears in the *Botanical Magazine*, t. 6504.

FORESTRY.

PLANTING FAILURES.

IT is safe to say that the worst failures in forestry work occur at planting time. By failures I mean the trees that die in the first or second year after planting, and through preventable causes.

By far the greatest portion of forest trees planted on private estates are still got from public nurseries, and it may be useful, in the first place, to give an approximate estimate of the cost of plants and planting per acre of different species, mixed or pure, exclusive of fencing and other incidental expenses, so that the planter may have some idea what failure means.

At the present time the cost of planting an acre of mixed species, about 3 feet apart each way, of Larch, Scotch Fir, Spruce, Oak, Ash, Sycamore, and such species as will succeed together is about £6 5s., at 25s. per thousand, according to catalogue prices, and to that figure must be added 20s. to 30s. per acre for pitting and planting. If the work is done by contract and the selection left to the nurseryman, it may be done for less, but no such contracts should be entered into unless they are based on correct sylvicultural principles. Of course, planting wider than 3 feet each way will reduce the cost, but on poor waste ground and high-lying exposed situations 3 feet is wide enough, if anything is, to ensure an overhead canopy in good time, and 3½ feet or 4 feet should not be exceeded in the most favourable situations, except with the Douglas Fir, which requires from 4½ to 5 feet. If any considerable proportion of Japanese Larch be added to a mixed plantation it may raise the price per acre to £7 or £8 at present British prices, but at Continental prices the addition does not make so much difference.

A pure crop of Japanese Larch, 12 to 18 inches high, once transplanted and put in 3 feet apart, costs about £9 per acre for the plants alone, and a crop of pure Douglas Fir of the same size, 1,800 to the acre, 5 feet apart, will cost about £7 or £8 per acre for plants alone. Trees from Continental nurseries, at Continental prices, bring the cost per acre down about a half or more, but although the latter have usually good enough leads, they are not, as a rule, so sturdy nor so carefully transplanted, unless the conditions on that head by buyers are strict. I know the home and foreign trees well, and can vouch for the description which applies generally to the nursery stock in both cases. I am speaking of "planting-out" trees, not of one and two years' untransplanted seedlings, which are about equal, the Continental, if anything, being the taller. On the whole, one prefers British trees, but wishes the prices were lower. In one German nursery, where many millions of Japanese Larch and Douglas Fir are raised annually, not to mention other species, many English orders have not been executed this season because the species of the size wanted have been sold out. More and more trees are coming from Germany every season, and deliveries are just as quick as from home nurseries. There must be extensive planting going on somewhere, judging by the stocks raised and sold in this country from home and Continental sources, and extensive planters may understand what failure (exclusive of rabbits) of, perhaps, from 20 to 50 or even 80 per cent. year after year must mean, and such is not uncommon in both nursery and wood.

As to causes of failure, these begin with the species, for under equal conditions, as regards soil and climate, hardly any of our better-known forest trees have the same vitality and transplanting power. The Corsican Fir stands at the very bottom of the list as a bad transplanter between November and April; Pinus Pinaster, of similar habit, comes next, and the Scotch Fir third. The Austrian Fir will often stand more abuse than any other of its class and live. The broad-leaved deciduous species are different altogether. If they fail when transplanted from the nursery to the wood there is gross carelessness somewhere, either in the nursery or in the moving from the nursery to the woods. When an Ash, a Sycamore, an Oak, or an Elm has plumped its buds by October or November, no matter whether the leaves are still green or not, it is fit to transplant, and should be transplanted, and if it cannot be moved then it should be left till early spring.

From November till March has hitherto been the season recommended by foresters, indiscriminately, for planting all kinds of forest trees, but I will undertake to say that the dead and coldest season of the year is the very worst for planting, because the plants lose their vitality more or less when they most need it to resist extreme vicissitudes of weather.

But a large proportion of the failures in planting young forest trees are due to circumstances that occur between the time the trees are lifted in the nursery and planted out at their final destination. Such are careless lifting and exposure of the roots to the air and sun, causing them to shrivel up; careless packing; delay in transit; and careless final planting by the forester or ignorance on his part. I am writing now from well-known estates, where, in mixed plantations of Larch, Scotch Fir, Sycamore, Ash, etc., planted last year, at least 50 per cent. are now dead. That was the agent's estimate before I saw the plantations, and it was more than confirmed by counting the blanks in the rows. On another estate where the

Corsican Fir is popular, 10,000 seedlings had been got from two well-known nurseries, one in England and one in Scotland, 5,000 from each of the same age, delivered in the same week, and planted in nursery rows by the same man. A few months later the owner of the estate wrote: "There are 5 per cent. of A.'s lot now alive, while in B.'s lot there are failures, but not many. A. says he will send me a few more to make up for losses to some extent, but they will probably go the same way." I saw these lots a day or two later, and could not find quite 5 per cent. of living trees in the bad lot. I have seen worse failures even than this, in which all the trees were dead. The Corsican is a fine timber tree, and as easily managed as the Scotch Fir by those who know it and plant it at the right season, but otherwise, as the manager of a large and well-known nursery said to me, "it's a brute to move." He had just lost nearly a whole quarter. I have, I may say, miles of the true Corsican under my eye, all of which were planted between April and the end of May, with hardly a failure. They have outgrown the Scotch, and stand clear above them at all ages up to 20 feet or more. *J. Simpson.*

FOREIGN CORRESPONDENCE.

THE FLOWER INDUSTRY AT NICE.

IT is perhaps not known to many people that Nice owes its trade in cut flowers to the celebrated French author, Alphonse Karr. In 1852 Nice still belonged to Italy, and it was in this town that M. Karr took up his abode, after he had compromised himself in political intrigues. There he became a practical gardener, and the cut flowers which he exported to Paris were the more keenly sought after, coming as they did from one who was a prominent and caustic critic of the party in power at that time.

The cultivation of flowers for the market, which had hitherto only been carried on in the environs of Grasse, thus made great strides, and it has since become the principal industry of the Riviera town.

A special train leaves Nice every day during the blooming season, conveying northwards such flowers as Acacia dealbata, Roses, Carnations, Violets, Narcissi, Iris, Mignonette, &c. The horticultural establishments which exist for the providing of these flowers form the chief source of the prosperity of this part of France, and their produce, which is despatched in enormous quantities, commands prices varying from about threepence to two shillings per pound, according to the season.

Violets are mostly grown at Hyeres, Acacia dealbata at Cannes, Carnations at Antibes, and Roses at Nice. It is especially about the "Parc aux Roses" that I propose to write a short account, which I hope may interest the readers of the *Gardeners' Chronicle*. The Parc aux Roses is situated to the west of Nice, on sloping ground facing the sea, and is completely sheltered from the Mistral. It belongs to a well-known French botanist, M. Arbost, whose partner, M. Piedoic, is an experienced horticulturist. Their two specialities are Roses and Carnations. The latter have been grown with much care, and have produced flowers of great beauty and enormous size. At Turin, during the exhibition of 1904, they have met with great success, and I have heard that Queen Margaret of Italy said much in their praise, and added that she had never before seen Carnations of such beauty both as regards shape and colour. Continued success has attended this enterprise, and for that reason I decided to go and see it for myself.

All the Carnations are grown from the firm's own seed, and they owe the beauty of their colours to the scientific method and care with which they are selected. I was shown thousands of flowers of the superb Carnation Miss Willmott of a pale sulphur-yellow, with a greenish shade, merging into white at the edge of the petals. The flowers are borne on strong, firm stems, and the foliage resembles that of the "Malmaison" type. Several flowers measured from 10 to 12 centimetres in diameter. The variety is the result of a cross between "Malmaison" and one of the Nice Carnations

"Papa Guillot," another excellent Carnation, the colour of which is greyish-purple, marked with violet and flamed with rose, orange, and sometimes with pure yellow; it is a special race, and is not related to the Malmaisons. I also saw a new variety of perfect form and pure white, which had not yet been named, as well as many others with a wide range of colour. These specialists every year raise from 12,000 to 15,000 Carnations from seed, which are treated as annuals. Besides this, they take about 250,000 cuttings, which are grown under glass in a medium temperature.

There is also a plot set apart in which are grown all the species of Dianthus that are in cultivation, and there is a complete library dealing with the history of the Carnation and its cultivation.

The proprietors sell none of the cuttings or plants, and thus reserve for themselves the monopoly of the stock.

Alongside the Carnations, of which there are over 80,000 feet under cultivation, are grown the Roses, occupying an area of 100,000 feet. These flowers provide a succession of blooms from the end of October to June, and are despatched all over Europe, the principal towns of Russia, Germany, France, Italy, &c, being largely supplied by the flowers grown in the Parc aux Roses.

My visit, made in September of 1907, was of great interest, and I renewed it in March, 1908. I advise all amateurs and lovers of flowers who go to the South of France to do likewise,

FIG. 173.—AGAVE FEROX IN FLOWER IN THE "PARC AUX ROSES."
(See "The Flower Industry at Nice.")

as it offers many attractive features new to those who live in more northerly climates.

Shaded by old Olive trees, many of them a hundred years old or more, paths lead to the Mandarin groves, which produce yearly 80,000 Mandarins, and where Messieurs Arbost and Piedoic maintain a collection of 60 species and varieties of the genus Citrus. This collection is as interesting as it is unique.

There also exists here one of the most complete collections of Hydrangeas which it has been my good fortune to see, comprising as it does all the kinds that are met with in cultivation.

There are also some beautiful Palms, amongst which may be mentioned Cocos capitata, which bears a delicious fruit with the flavour of a Pineapple. Various kinds of Eucalyptus grow near and shade the house, and a huge plant of Poinsettia pulcherrima produces 2,000 heads of bloom at Christmas time. Many hundreds of Kentias are grown, besides large numbers of Chamærops of various kinds, which are chiefly exported to Belgium. *Henri Correvon, Geneva.*

VEGETABLES.

THE CABBAGE TRIBE.

Of the various culinary vegetables which find a place in gardens there is scarcely one that is of greater importance than the forms of Brassica oleracea, which includes the common varieties of the hearting Cabbage, Brussels Sprouts, Kales, Broccoli, and Cauliflower. In the *Transactions of the Horticultural Society*, 1821-24, M. A. P. de Candolle describes six races, varieties, and sub-varieties of the wild Cabbage (Brassica oleracea): 1st race, B. o. sylvestris or wild Cabbage; 2nd race, B. o. acephala, tall or open-headed Cabbage; 3rd race, B. o. bullata, the Savoy or blistered Cabbage; 4th race, B. o. capitata, round-headed Cabbage: 5th race, B. o. caulo-rapa, Kohl-rabi or Turnip-rooted Cabbage; 6th race, B. o. botrytis, Broccoli, Cauliflower or flowering Cabbage. The second type is Brassica campestris, or field Cabbage, the 1st race of which is B. campestris, Colza; 2nd race, B. c. palmaria, intermediate between the field Cabbage and B. c. napa. As my observations will be strictly confined to these races, I will not touch on Brassicas of the Turnip family—B. Rapa oleifera, the long-rooted or globular varieties, or of the various types of Radishes, Raphanus sativus. Many of these, according to M. de Candolle, are cross-breds, accidentally produced and preserved by the care of the cultivator.

The first sowing of the year as regards the true garden Cabbages may be made in the early days of the month of January in broad seed pans, wooden trays, or on mild hot-beds in a moderately rich loamy soil, the seeds being thinly sown and very slightly covered with some of the same kind of soil. If sown in pans or trays, these may be placed on shelves close to the glass in a house having a warmth of 58° to 60° at night. Water should be afforded with great care, and the soil shaded with paper till germination has taken place, but afterwards only a very slight kind of shading is needed for a few days during the hours of strong sunshine. The chief object is to secure a robust growth in the seedlings, and to prevent an attack of the "damping off" fungus by admitting as much air to the house as is practicable, having due regard to the well-being of the other plants growing in the house. When the true leaves begin to show on the seedlings, the outside conditions will have begun to improve, thus enabling the gardener to remove the seed pans, to rather cooler quarters, but still close to the roof glass, though with no more shading of paper, &c., thenceforward. With four leaves showing on the little plants, pricking out will be called for, the plants being set out at 1½ inches apart on soil made moderately firm by using a small board or flat trowel for the purpose; and towards the end of the month of February the pricked-off plants may be placed in a cold pit capable of being heated in the event of the weather being frosty; otherwise a sprinkling of straw or Fern fronds (bracken) and a mat over all will prevent the temperature of the frame becoming too low. For this early crop the following varieties are suitable: Ellam's Early, Beaconsfield, a dwarf, conically-shaped Cabbage, a little later than the first-named and an introduction of Messrs. J. Veitch & Sons, Chelsea, who are likewise offering this year a fine early Cabbage named Incomparable. Should there be a demand for Cabbages at an earlier date, they can be obtained from the late summer sowings of the previous year, the varieties named may be planted in frames and afforded a bottom heat from a bed of tree leaves, which may not exceed 65° to 70° Fahr. On the Continent, in parts where the winters are too severe to allow of Cabbages being grown at all out of doors in the winter months, it is a common practice in gardens to grow varieties of white Cabbage and of Savoys in frames heated by dung beds or dung and tree leaves, and by careful management very nice produce is obtained if planted at 1¼ to 1½ feet apart. Some of the favourite varieties of the French gardeners for planting as early crops in frames and the open ground are the following: Précoce de Tourlaville, one of the best for planting at the seaside in the open; and the heart-pointed: Joanet (Nantais), very early. Of Savoys mention may be made of Early Saint Jean, a small sort distinct from all others, very early, and the heart of the shape of the variety Oxheart. The stem is extremely short. Early Ulm is a delicious variety, coming into use in a brief space of time.

Cabbage seeds may be sown from February till May in the open air on warm borders, preferably those having south and west aspects, the soil being well firmed by treading regularly all over, and otherwise prepared for sowing by raking it smoothly and removing all large stones and rubbish. The soil should not have received any manure recently, it being better for the seedlings if they are not too succulent on being planted. Some gardeners sow the seeds in very shallow drills drawn at not less than 1 foot apart on beds laid out at 5 feet apart, covering the seeds, which should be thinly sown, with the back of an iron rake and passing a wooden roller over the seed-beds afterwards. Others sow the seeds broadcast and thinly, either method having some advantages pertaining to it—the drilling allowing of an easy way of keeping down weeds, and broadcasting affording more space per plant. A loose-hearted Cabbage, with thick white ribs to the spreading leaves, is Couve Trouchuda. This, as it is not hardy, must be consumed before the end of November, and, in order to reach its full size, it should be sown towards the end of the month of February. According to the local climatic conditions, the important early autumn sowings of Cabbages for affording a supply the following summer may be made from the second week of August in cool climates such as those of northern England, and in Scotland and the northern counties of Ireland. In other parts, having regard to altitude and exposure, the end of the month and early in September is a sufficiently early date. The following varieties may be recommended among the older ones: Hardy Green Colewort, Heartwell Early Marrow, Little Pixie Colewort, Mein's No 1, Nonpareil, a capital variety that sometimes turns in all once, or nearly so, and Carter's Reliance. Of newer varieties Incomparable, a selection of Mr. Allan, gardener at Gunton Park, may be named, and Main Crop, one of the Veitchian introductons.

Brussels Sprouts, Borecole, Kale, and Broccoli may be sown in March. Of the last-named vegetables, two sowings, one at the beginning and the second at the end of the month, should be made of the early Penzance, a very early Broccoli, with compact white heads, of moderate size; Early White Cape, succeeding the Penzance; and the famous Walcheren. In warm districts it is advisable to make still another sowing of these three varieties on the chance of obtaining a crop, should the weather in November and December not be too severe. In May the Purple Cape may be sown for cropping in the autumn, and there are other desirable varieties, of which Self-Protecting Autumn is one of the most useful, as it forms a good succession to Autumn Giant Cauliflower. In dry soils the land on which Brassica seeds are to be sown should not be dug till immediately before the sowings take place, as owing to the rapidity with which such soils lose their moisture near the surface, early digging is a fertile cause of irregular germination of the seeds. The seed-beds should be securely netted, or the birds will greatly lessen the number of the seeds before they sprout, and mutilate and devour the plants in the young stage. *F. M.*

BELGIAN HORTICULTURE.

UTRICULARIA HUMBOLDTII.

An interesting feature of the establishment of M. Th. Pauwels, of Meirelbeke, Ghent, at the present time is a good plant of the rare and very beautiful Utricularia Humboldtii in flower.

The species was discovered in 1840, in a swamp on Mount Roraima, in British Guiana, by Schomburgk, who described it as one of the most beautiful creations of the vegetable kingdom. A coloured plate and description were given, the species being dedicated to the renowned traveller and naturalist, Baron Humboldt. Schomburgk remarks that the plant bears the Indian name of "Roraima iperua," or "Flower of Roraima," and in his delightful book, *Botanical Reminiscences in British Guiana* (p. 69), he alludes to it as follows:—"Here spread before us lay a small marshy plain, on which Flora had assembled her most beautiful children, where the charm of flowers had culminated. The whole plain was covered with the dark-blue Utricularia Humboldtii, the most beautiful species of the genus, with red-tinted flower-stalks from 3 to 4 feet high, from which three or four of the curious flowers were suspended." This sight so impressed Schomburgk that he named the place the "El Dorado Swamp," after the treasure city Raleigh and others sought in Guiana. The figure was repeated in the *Annals de Gand* (1845, p. 357), and in *Flore des Serres* (t. 1390), in the hope of leading to its introduction, but this event did not take place until 1884, when Messrs. Sander and Sons' collector, Siedel, obtained plants of the Utricularia while on his adventurous journey after Cattleya Lawrenceana. It did not flower immediately, however, but on April 12, 1892, a plant was exhibited in fine condition at a meeting of the Royal Horticultural Society by Baron Schroder, which was unanimously awarded a First-class Certificate by the Floral Committee.

Utricularia Humboldtii is a semi-aquatic plant, producing tufts of broadly-reniform leaves from 2 to 5 inches across, on petioles from 6 to 12 inches long and scapes from 2 to 4 feet high, bearing from 6 to 18 large, violet-coloured flowers, about 2 inches across, three or four of them being expanded at the same time.

This beautiful species grows also on the Kaieteur Savannah, in British Guiana, as we learn from Sir Everard F. im Thurn, in the very interesting account which he gave of his ascent of Mount Roraima in 1884 (*Trans. Linn. Soc.*, ser.

2, ii., p. 256). The Kaieteur Savannah is much like Roraima in many features of its flora, and here the Utricularia grows in abundance in the pools of water which collect in the bases of the leaves of a giant Bromeliad, Brocchinia cordylinoides, which Mr. im Thurn describes as by far the most striking, as it is also the most abundant plant on the Savannah. "This gigantic plant, so striking as to compel notice even from the most unobservant traveller, is ranged in enormous numbers on the Kaieteur Savannah, and, indeed, makes, to a large extent, the strangeness of that strange scene. There the height of a full-grown specimen, under favourable circumstances, is about 14 feet, and, in the older specimens, at least, the crown of leaves is supported on a tall bare stem. It seems also there to flower abundantly. In the axils of the leaves of this Brocchinia, and only in that position, grows a very remarkable and beautiful Utricularia (U. Humboldtii, Schombk.), with flower stems 3 to 4 feet long, supporting its many splendidly large, violet flowers."

At Roraima "the Brocchinia, too, grew in parts so densely that we had to walk, not on the ground, but on the crowns of the plants, which, as we crushed them with our feet, poured from the axils of their leaves the remarkably abundant water which they retain. Nor must I omit to mention that in the bush-belt a very few plants (I saw not more than three or four) of Utricularia Humboldtii of the dark Roraima form were growing in the axils of the Brocchinia leaves, as at Kaieteur."

The Utricularia occurs both at the Kaieteur Savannah and on Mount Roraima, "but at the former station it apparently always grows floating in the water retained in the leaf-axils of the Brocchinia; while on Roraima it grows abundantly with its roots in the ground, and only very rarely in close association with the Brocchinia. The Roraima plant is, moreover, far more beautiful, and its flowers are of a more intense colour than is the Kaieteur plant. The latter circumstance is probably due to the greater vigour which the plant displays when its roots are in the ground

These facts may afford a hint to cultivators as to the method of treatment, and it should be added that M. Pauwels grows his plant in a large tub of leaf-soil, with some sphagnum-moss, the compost being put in quite loosely, and just allowed to settle with its own weight and the water applied. A warm climate is, of course, necessary. It is a most beautiful species, and the problem now is how to grow it with something like its native vigour. *R. A. R.*

NURSERY NOTES.

H. B. MAY & SONS, EDMONTON.

THE display of Ferns, mainly varieties of hardy British species, which was made by this firm on May 12, at the Royal Horticultural Hall, and for which a Gold Medal was deservedly awarded, evoked the more admiration since no such exhibition has been made since the Fern Conference of 1891, now 17 years ago, and, as a consequence, the capacity of our native Ferns as high-class decorative foliage plants has been known to but few connoisseurs The exhibits at the Conference were almost exclusively from private collections, and it is, therefore, a matter of congratulation that a trade exhibit of such merit should be put before the public as indicating a step towards that popularity which the plants undoubtedly deserve. Messrs. May & Sons have long stood in the forefront of exotic Fern growers, and they are to be heartily congratulated on their adoption and successful culture of this long-neglected branch of horticulture, the specimens shown of Hartstongues, Polystichums (fig. 174), Lady Ferns, Lastreas and other species clearly demonstrating the immense advance which has been made by selective culture of the material afforded by wild "sports" found in our native fernery districts. A recent visit to their three extensive nurseries at Edmonton and Chingford afforded us a still more vivid idea of what can be done with these plants in skilful and painstaking hands. Hundreds of thousands of them, in all stages of growth, from the tiny primary frondlets to huge fully-developed specimens occupy a large range of houses and frames, shelves and open spaces, while in one special house we saw hundreds of pots, pans, and shallow wooden boxes, in which the still earlier stages of sown spore and green prothallus indicated the source of the immense harvest around us, including that of the innumerable exotics of which the firm have so long made a speciality. A merely flying visit naturally precluded anything like a thorough inspection of the numerous houses, many of them hundreds of feet in length and crammed with verdure, which represent what may be termed the "coddling" department for many of the rarer

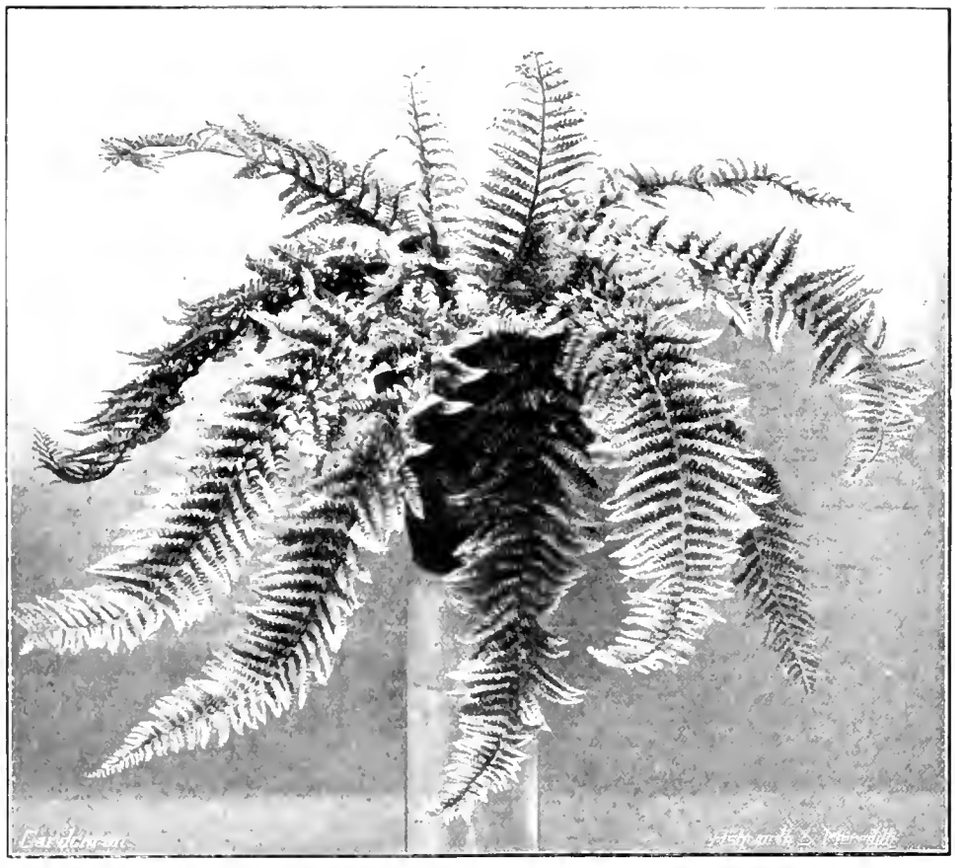

FIG. 174.—POLYSTICHUM ANGUSTIFOLIUM DIVISILOBUM DENSUM IN THE COLLECTION OF MESSRS. H. B. MAY AND SONS.

species of exotic plants, since Ferns are by no means exclusively grown. House after house, for instance, was seen to be filled with Palms, Kentias, Arecas, Latanias and Cocos by the thousand, Lapagerias, alba and rosea, drape the doors and sidelights of others, a glimpse through which shows a tropical jungle hung with festoons of white and ruddy waxen bells. While still inspecting the comparatively cool range of houses, we see magnificent specimens of temperate or sub-tropical Ferns, among which we note particularly the huge, graceful, pendulous frond masses of Davallia fijiensis and f. gracillima, D. robusta, D. plumosa, D. tenuifolia, D. Veitchii, D dissecta, and other delicately-cut forms, while, as a contrast, the broad, dark green, crisp, leathery fronds of D solida superba are massed together 4 or 5 feet through with fine effect. Contrasting too with these, and on quite different lines, we have the curious Platyceriums, with their two kinds of fronds, broad, barren ones, apparently adherent to the cork masses or tree Fern trunks to which they are attached, while more or less projecting and pendulous are the stag, or elk-horn-like, fertile fronds showing various kinds of forking. P. grande, Veitchii, alcicorne, a. divergens Mayi, biforme, æthiopicum angolense and Willinckii are all here in fine form, each presenting its distinguishing peculiarity. As a sort of link between these and their more delicate neighbours we saw Drynaria quercifolia with huge oakleaf-shaped barren fronds on Platycerium lines, but with long, pinnate, fertile ones, 5 or 6 feet in length, glossy green and very handsome. Some of the Acrostichum gems have equally diverse fronds. Drynaria musæfolia next attracted our attention, since, though the fronds are simple, the veins are dark in colour, and form a peculiarly beautiful pattern all over them. The Davallia family itself provided its own foil, so to speak, in the shape of D. heterophylla, a charming little creeping Fern, with simple lance-shaped, barren fronds and prettily crenate and narrowed fertile ones; D. minima is a still tinier plant, while D. retusa forms another curious variant, with graceful, open fronds, the sub-divisions of which are squarely terminated, resembling Asplenium præmorsum. We next observed in close proximity, Hymenodium crinitum, with broad, bat-shaped, hairy, leathery fronds, and that curiously pretty dwarf Fern Rhipidopteris peltata, with fronds like little radiating stars on stalks an inch or so high; two forms about as diverse as can be conceived. Polypodium Knightii, a gem of the first water, occupied a prominent place with its long, slender, pinnate fronds, the edges of which are cut and fringed precisely like a beautiful Welsh Polypody at its best; indeed, it represents an analogous sport in an Australian species. The Fern specimens are so numerous and so varied in form that we can merely mention a few of them, and, therefore, approach the conclusion of the exotic

Fern list by a special reference to the Nephrolepis group, which have given such wonderful varieties in late years. As a special article has already been devoted to these in the issue for December 29, 1906, p. 444, we will merely state that all the best varieties are seen here in abundance and as magnificently-developed specimens. In some houses, indeed, one can only creep through a narrow track between, as it were, a dense jungle, N. E. todeoides, Wittmanii, elegantissimum and, last but not least, Amerpohlii, which, though dwarf, holds its own with the best of the plumose section. The only houses which could present an equally fine effect, though on other lines, were those containing masses of that peerless Maidenhair Fern, Adiantum Farleyense, another of the firm's specialities. The many market forms of Pteris cretica, serrulata and tremula were there in myriads, and it was one of the most interesting features of our visit to note how, stage by stage, the plants are brought on from the invisible spore to the saleable plant in such large numbers, the whole constituting a veritable Fern factory. We must advert specially to the comparatively new speciality of Messrs. May's firm, viz., the British Fern varieties. In the course of some 30 years' cultivation of these long-neglected plants, we have seen many collections, but never finer, healthier, or better-developed specimens than are most of those at Edmonton. Naturally, some slow-growing species demand more time for full-size development than has so far been available for culture. Nearly 1,000 distinct varieties are embraced in this collection, while of exotics there are as many more. In other directions than Ferns, we may mention houses glowing with ruddy-leaved Dracænas of some 80 odd kinds, gold and green and red Crotons in about 130 varieties, Bouvardias in 30 or more varieties. Tree Carnations and Clematis, Roses, Gardenias, Ixoras, Ficus, Begonias, Ivies, and scores of other kinds of plants figure in one or other of the three nurseries at Edmonton, Millfield, and Chingford. *C. T. Druery.*

The Week's Work.

PLANTS UNDER GLASS.

By THOMAS LUNT, Gardener to A. STIRLING, Esq., Keir, Perthshire N.B.

Gesnera.—Plants that are to flower in winter should now have their roots shaken from the old soil and the tubers potted up into 5-inch pots, putting four tubers in each pot, and using a compost consisting of peat, leaf-mould, loam, and sand. The tubers should be covered with about 1 inch deep of soil placed loosely on the top. Keep the soil rather on the dry side until the tubers have started into growth. Place the pots in a heat of about 65° to 70° on a base of sand or gravel, or any other material that will hold moisture. Syringing is not advisable, therefore damp frequently all the ground surfaces in the house, and shade the plants from bright sunshine. Allow ample room for each plant to develop perfectly, as the foliage of some varieties is very handsome. When the pots have become well filled with roots, the plants should be shifted into pots 7 or 8 inches in diameter, and in these they may flower. Care should be taken that there is no mealy bug in the house in which they are cultivated, as Gesneras are very liable to attack by this pest. Keep a sharp look-out also for thrip, and on the first appearance of the pest let the house be fumigated with the X.L.-All vaporiser.

Streptocarpus.—Hybrids raised from seeds this spring should now be pricked out into small pots containing a compost of loam, leaf-mould, and sand, with a little manure from a spent Mushroom bed well mixed with it. If given a position in the warm fernery and shaded from bright sunshine the plants will succeed well. Older plants that are now flowering must be given less heat, and they will need frequent applications of liquid manure. Fumigate with the XL.-All vaporiser on the first appearance of green fly.

Ficus radicans variegata.—Insert cuttings of this variegated Ficus for raising plants to cover a wall in a stove or intermediate house. Seven or eight cuttings may be placed in a 6-inch pot, and they will quickly make roots. Afterwards place the pot against the wall, and in a very short time the plants will obtain hold of the wall. This is all that is required, as the Ficus will live upon the wall. This variety has a much brighter appearance than the type-species, and a wall covered in this manner gives little or no trouble in keeping it clean.

Winter-flowering Begonias.—Plants of Gloire de Lorraine raised from leaves that were propagated early in the spring are now ready for repotting into 6-inch pots. Use a compost consisting of leaf-soil two parts, sand one part, and light loam or peat two parts. Be careful not to damage the young roots during the process of potting. Therefore, only press the compost moderately firm around the ball. Begonias are moisture-loving plants. Therefore, it is the more necessary that the pots should be well drained. Place the plants close to the glass in an intermediate house, and promote an abundance of atmospheric moisture at all times. Provide the plants with shade from bright sunshine, and keep a sharp look-out for small yellow thrips, or these will be likely to spoil the foliage. Syringe the plants overhead twice each day during favourable weather. Cuttings of the Begonia Gloire de Sceaux inserted last April will also be ready for potting now. Employ a compost of loam two parts, leaf-mould one part, sand one part, and a small quantity of manure from a spent Mushroom bed. In other respects this variety should be treated similar to Gloire de Lorraine.

THE HARDY FRUIT GARDEN.

By F. JORDAN, Gardener to The DOWAGER LADY NUNBURNHOLME, Warter Priory, Yorkshire.

Summer pruning and training.—All trees are now making rapid growth, and should be given attention at short intervals, pruning some shoots and tying in others to extend the trees or to replace worn-out branches. Pears are generally the first to claim attention. Wall trees and cordons should be examined in the first instance when the shoots have made seven or eight leaves. Pinch such shoots to six leaves, and later, when the top buds have again commenced to grow, pinch the second growth back to two leaves. By this system the trees will not suffer much check, but the sunlight will have free access to all parts of them. This is much better than allowing the shoots to grow until July and then using a knife to shorten them, this latter being a method that encourages strong roots to form, even when the trees are worked on dwarfing stocks, and the trees eventually become gross and unfruitful, rendering root pruning necessary. Cordon trees growing on walls require frequent pinching to keep them in a fruitful condition. The same methods should be followed with pyramid Pears, Plums, Apples, and Cherries, with slight modifications according to varieties. Commence pruning the most forward trees first, and allow the leading shoots to extend according to the amount of space available, only shortening those that have filled their allotted space, and pinching the points from those that are growing too strong. As soon as the operations of stopping and disbudding are completed, tie, or nail in, the leading shoots in the desired direction. Gather all the prunings every day and burn them, and vigorously syringe the wall trees daily with clear water.

Thinning fruits.—Apricots should now be finally thinned. All trees growing in well-drained borders should be given another good soaking of water. Look over the trees at frequent intervals for maggots, which are unusually prevalent this year, and other insects, such as woodlice, ants, &c., which should be trapped before the fruits commence to colour. Thin the fruits of Plums on wall trees if they have set too thickly, and keep the roots well supplied with water. Pears should be thinned where necessary, but care should be taken not to thin them too freely if the Pear midge is in evidence. First pick off all deformed fruits from the trees and collect those that fall to the ground and burn them. If persevered with, this treatment will greatly lessen the pest. Early varieties of Apples, such as Mr. Gladstone, Beauty of Bath, and Irish Peach should be thinned if the trees have set heavy crops. American blight, which is now making its appearance, should be carefully watched and the trees sprayed with No. 2 fluid, as recommended in the "Calendar" printed in the issue for February 1 last.

THE FLOWER GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

Tender bedding plants.—Most of the plants having been already put into the beds, the more tender subjects having now been carefully hardened, may also be planted. Begonias that are in unheated frames are now good plants, and should be transferred to beds which have been specially prepared for them by the addition of leaf-mould and decomposed manure. It being necessary to water these plants frequently, we keep the revolving sprayer playing over their heads in the hottest weather, and it is very beneficial. Frequent attention must be given to such plants as Verbenas and Petunias in order to peg down the growths and to remove the flower trusses as soon as they become unattractive. Special attention in the matter of watering must be given to plants growing in vases, as these are generally in rather exposed positions, and therefore dry very quickly. Stake and thin out herbaceous plants as often as necessary. Dahlias will need to have their side shoots staked, and this is better done before the roots extend far into the ground. Leave about five shoots and the main leader to each plant. The centre growth should have been secured to a stake at the time of planting, and the four side growths must now be given a separate stake each. The effect will be quite spoiled if they are bunched up tightly.

The wild garden.—Myosotis and Narcissus are especially decorative plants in the wild garden. The Daffodils have flowered, but if there is Myosotis amongst them, in order that it may mature its seeds, the grass must not be cut quite so early as if Daffodils alone were cultivated. At the same time, strong-growing weeds that interfere with the development and flowering of other plants should be kept down. It is good practice, when removing Myosotis, Polyanthus, and Wallflowers from the flower garden, to plant a few of these in the wild garden, or on bare banks; the seeds then become scattered, and the seedlings flower in the following spring. Seeds of such plants as Honesty and the common Valerian may be sown broadcast. When banks planted with spring-flowering plants have been cleared, vacant spots may be very suitably filled with such plants as Delphinium "Blue Butterfly," Nemesia, dwarf Antirrhinum, Marigold "Legend of Honour," Viola, Tagetes, Gazania, Nasturtium, and Verbena.

Nymphæa.—The present is a good time for planting Water Lilies. They succeed best in natural pools or slow-running streams, where the depth of the water is from 1½ to 2 feet, and in a position that is exposed to sunshine. They require about 1 foot deep of soil to root into, and it is a good plan to have this soil in shallow baskets which will readily sink to the bottom. Casks or tubs may be used, but they must be sunk until they are level with the base of the pool. Other water plants suitable for planting at the present time include Sagittaria, Peltandra virginica, Aponogeton distachyon, Juncus zebrinus, and Butomus umbellatus.

Planting.—Such species as Rhododendrons (including those known in gardens as Azaleas), Kalmia, Lilac, Laburnum, Prunus, &c., which have been forced into flower in the houses may now be planted out into their beds in the open, or be plunged in pots into beds of ashes. The plants should be frequently syringed during the summer months, and every attention given them in respect to root-waterings. Lily of the Valley which has been forced may also be planted out into a shaded position. This plant requires deep, rich soil, and succeeds very well under the shade of a wall facing to the north. Hyacinths and Tulips may be planted in the wild garden.

Lawns and paths.—Lawns require very frequent mowings this season in order to keep the grass short and prevent it producing flower-stems. Sweep and roll the paths as often as may be necessary to keep the surfaces firm and smooth.

FRUITS UNDER GLASS.

By T. COOMBER, Gardener to LORD LLANGATTOCK, The Hendre, Monmouthshire.

Cucumbers.—Plants that have been bearing fruit for a long time will become exhausted unless they are encouraged to make fresh growth, by being top-dressed with a new compost, which may consist of light, turfy loam, horse manure, and flaky leaf-mould, and by supplying the roots with occasional waterings of tepid liquid manure. High temperatures and moist atmospheres must be maintained, employing sufficient artificial heat at night and on dull days, carefully ventilating the house, but closing it early in the afternoon to conserve solar heat. Frequently damp the floors and syringe the plants in the morning and again at closing time. This practice, if well followed up, and accompanied by light cropping, will quickly renovate plants that have become weakened by heavy cropping, and it will keep them free from red spider, but old growths should be thinned out and young ones laid in and stopped at one leaf beyond the first fruit. If new plantations are required, young plants should be raised for the purpose. It is from young plants that fruits of the best quality are to be secured.

Cucumbers in frames.—The weather has not been favourable to crops recently planted in frames, and it may be found expedient to add fresh fermenting material around the sides of the frames. Keep the growths properly thinned, stopped and regulated, and be careful not to over-water the plants, or to create, by syringing, excessive atmospheric moisture. The best time to syringe the plants is on bright days, when the lights are being closed for the day, which should be done early to secure a good heat. Keep the lights covered at night, and lightly shade the plants during the middle of the day from powerful sunshine. In many gardens planting in frames is delayed until accommodation can be found for the plants in the frames from which the early crops of such vegetables as Cauliflowers or Potatos have been cleared. In such cases the fermenting material may require to be turned and an addition made to it, afterwards putting out the plants as recommended in a previous "Calendar."

Tomatos.—Houses containing plants with ripening fruits should be freely ventilated, and the atmosphere kept dry. Extreme fluctuations of moisture in this respect would damage the fruit by causing it to split. Careless watering of the soil will also promote similar evil effects, and the soil should, therefore, be kept in a uniformly moist condition, at no time allowing it to become very dry. Apply light top-dressings of fresh compost, artificial fertilisers, or water the roots with liquid manure. Gather the fruits as they ripen, both in order to prevent them being spoiled by over-ripening and for the sake of lightening the burden of the plant. Regularly remove lateral growths, but refrain from the practice, sometimes followed, of amputating the principal leaves. It is a custom at The Hendre, in the case of cordon plants, to leave, during the early stages of growth, a spur near the base of each plant, from which—after the lower part of the plant is relieved of fruit, and at the same time of leaves also—a young growth is trained over the old stem, ultimately entirely taking its place. By this means, fruit ripens upon the bottom of the new rod before the old one has finished the crop at its top, and a continual supply of fruit from the same plants is kept up for a long period. At this season accommodation can usually be found for Tomato plants in structures that have contained Strawberries, and such plants should furnish a supply of fruit until at least mid-winter. Avoid using a rich or a large body of compost, as, in either case, an over-luxuriant growth would take place while the plants were in a young state. A better plan is to secure sturdy plants and refrain from nourishing them with stimulants until they are laden with fruit.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Major G. L. HOLFORD, C.V.O., C.I.E., Westonbirt, Gloucestershire.

Cymbidium.—This genus was never held in higher estimation than it is to-day. The plants have become special favourites, and in some gardens a house is set apart for their culture. The flowers of many are of great beauty, and some yield a grateful perfume, while for lasting qualities some of them have few equals. The following showy kinds are well deserving the attention of every Orchid grower, viz., the species C. erythrostylum, C. Lowianum, and its variety concolor; C. eburneum, C. Mastersii, C. Sanderi, C. Hookerianum, C. tigrinum, C. giganteum, and their hybrids, C. Bullianum, C. insigne Ansonii, C. Low-grinum, C. Lowio-eburneum, C. eburneo-Lowianum, C. Winnianum, C. Wiganianum, C. Tracyanum, C. Holfordianum, C. Colmaniæ, and C. Lowio-grandiflorum. That these plants grow best under cool, intermediate conditions is now generally recognised. Thus treated, they suffer less from insect pests, and they thrive and flower better than when grown in a higher temperature. I think it is the cooler treatment these plants have received of late years which has caused them to flower more freely and brought them into the repute which they hold at the present time. Cymbidiums are for the most part strong-growing plants, having thick, fleshy roots, and during their growing season, especially when making up their growths in autumn, abundance of water at the roots is needed. At all other times they should be treated as ordinary greenhouse plants, always allowing them to become dry before giving the roots a thorough soaking with water. The plants require shading from strong sunshine, and the atmosphere of the house should be kept sweet and fresh by a judicious use of the ventilators, while the surroundings should be kept moist, and the foliage freely syringed both morning and evening when the days are fine.

Repotting.—All the above-mentioned kinds are now past the flowering stage, and new growths for the present season are more or less advanced. Any necessary repotting should now be carried out, but refrain from disturbing the plants as long as the soil is not sour and the receptacles afford sufficient room for the development of the season's growth, as plants in a root-bound state are always more productive of flower-spikes. If large specimens are required, young, healthy plants should be shifted on, causing as little root disturbance as possible, breaking the pots of those that are root-bound to extricate the roots without injury. Large specimens that have become exhausted are best broken up and the pieces potted separately, it being much better to grow on young plants into specimens than to make up large pots from small pieces. The new pots, or pans, should be clean, and of sufficient dimensions to accommodate the plants for a period of two or three years. Plenty of good, open drainage should be afforded, and the crocks covered with a layer of thin turf. Cymbidiums, for the most part, require potting in strong soil, and this should be a mixture of three-fifths turfy loam, one-fifth turfy peat, and one-fifth sphagnum-moss. Use these in as lumpy a condition as possible, adding plenty of crushed crocks and silver sand to keep the whole porous. I have tried manures for these plants, but the plants did not succeed so well with as without it. Therefore, I do not recommend using manures of any kind in the compost. The only thing of the kind I find beneficial without having ill-effects is weak, liquid cow-manure, and then only when the plants are root-bound. In the process of potting the soil should be made moderately firm about the roots, and the base of the plant kept about 1 inch below the rim of the pot. Use the materials in a moderately moist state, thus no water will be needed for a week or 10 days after repotting, when they should be given a thorough soaking, which will suffice for a long time.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree, Hertfordshire.

Potatos.—By this date the Potato crops in all localities should be sufficiently advanced to complete the work of earthing up the plants. Make sure that the surface of the soil is first thoroughly freed from weeds by flat hoeing it. When extra fine tubers are required for any special purpose the growths should be thinned to two or three of the strongest shoots. This is easily accomplished by placing the feet near the plant and drawing the weakest growths out with the hand.

Vegetable Marrows.—Plants which were started early in portable frames should now be in full bearing, the lights and frames being entirely removed. A thorough good surface dressing of loam and half-decayed manure should be applied in equal parts, and the growths thinned, regulated, and pegged down. The value of this practice over that of the ordinary way of cultivation will be fully demonstrated, as not only will the plants treated in this manner be in the height of bearing when those grown in the open are only just planted, but they will continue to bear quite as freely, if not more so, until frosts occur in the autumn. Plants raised from later sowings may now be put out on well-prepared beds.

Turnips.—After this date, and during dry, hot weather, much trouble is often experienced in keeping up a regular supply of sweet, tender bulbs. The Turnip flea frequently is very troublesome, arresting the growth in its early stages, and often completely eating up the plants when in the seed-leaf. Frequent small sowings should be made of the varieties Snowball, Jersey Lily, and Red Globe, choosing as far as possible the coolest and most shady part of the garden. The seed should be watered in when sown, and I have found it a capital plan to strew the surface with finely-mown lawn Grass about half an inch thick, which not only keeps the ground cool, but is also distasteful to the Turnip flea. Earlier sowings should be thinned before the young plants become drawn. Apply fresh soot once a week and a little vegetable manure. Keep the ground constantly stirred with the Dutch hoe. Early sowings which have matured should be lifted and stored in sand in a cool place at the foot of a north wall.

Spinach.—Few vegetables are more in request the whole year round than Spinach, or more difficult to procure during the height of summer, especially on shallow soils and in the southern districts. The most satisfactory way to ensure a constant supply is to make a small sowing once about every 10 days on land which has been well enriched and where there is a certain amount of shade, the most suitable places being between the rows of tall beans and peas. Thin out the plants to 6 inches apart. New Zealand Spinach which was raised in heat ought now to be planted out on a well-prepared piece of ground, either on a south or west border.

Cardoons.—These should now be firmly established and growing away freely. It is essential that plenty of moisture be afforded them all through the growing season. The plants should be not less than 18 inches apart and a stout stake placed to each. Give the surface a good mulching of horse-droppings. Cardoons should be grown quickly, and from eight to 10 weeks is necessary to blanch them well.

Dwarf Beans.—Plants that are growing in unheated frames will now need an abundance of ventilation, and the lights may be removed entirely during genial weather. Apply a dressing of half-decayed horse manure to the roots just before the plants come into bearing. Continue to make small sowings in the open garden at fortnightly intervals.

Water supply.—One of the most serious hindrances to successful vegetable gardening in many places is due to the inadequate provision that has been made for a suitable supply of water, for during some seasons, in the absence of a good supply, it is impossible to obtain crops of the highest merit. No kitchen garden should be formed without making arrangements for sufficient water, and wherever it is possible a basin or pond should also be provided. Though water obtained fresh from the pipes is preferable to none at all; it is not to be compared with that which has lain for some time exposed to the influences of the atmosphere. The best time for applying water to plants is during the afternoon and early in the evening. Sewage or drainage from the farmyard are both of great value for most crops, but in all cases such liquids should be properly diluted. If the foliage of nearly any kitchen garden crop be damped by spraying in the evening after a hot day, the effect is beneficial, especially if the water is tepid at the time it is applied. This is the case even if the soil is sufficiently supplied with moisture at the time.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden W.C.

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see*

APPOINTMENTS FOR THE ENSUING WEEK.

WEDNESDAY, JUNE 17—
Roy. Bot. Soc. Summer Exh. (3 days). Yorkshire Gala, York, Jubilee Exh. (3 days).

THURSDAY, JUNE 18—Linnean Soc. meet.

SATURDAY, JUNE 20—German Gard. Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—59·1°.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, June 10* (6 P.M.): Max. 75°; Min. 58°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London—*Thursday, June 11* (10 A.M.): Bar. 30·2; Temp. 67°; *Weather*—Bright sunshine.
PROVINCES.—*Wednesday, June 10* (6 P.M.): Max. 70° Cambridge; Min. 55° Lancaster.

SALES FOR THE ENSUING WEEK.

WEDNESDAY—
Bedding Plants, Gladioluns, Pansies, Palms, Plants, Bays, Conifers, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 1.

FRIDAY—
Imported and established Orchids in variety, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

The Principles of Manuring.

It is a philosophical commonplace that we can only apprehend the external world through the medium of thought; indeed, it may be maintained that we know nothing of the external reality, but merely the workings of our own minds. But without pushing our scepticism to such a point, we must recognise in all our science, i.e., our attempts to reconstruct nature in terms of our mind, a tendency to rest content with explanations which fit in with our habits of thought, and to substitute simple, compact theories for the very complex operations of things in themselves. In other words, it is easier to let our minds work on straightforward "logical" lines than to puzzle out things as they are.

These somewhat trite reflections have been prompted by reading a recently-published work on manures by Dr. A. B. Griffiths,* the author of a long series of communications on questions connected with the nutrition and composition of plants, which have not always received a very cordial recognition. In this book we find developed at considerable length two ideas which we have every reason to consider fallacious, but which for the last half-century have exercised a powerful influence both on agricultural and horticultural practice. These two fallacies are, firstly, that the composition of a particular plant, as ascertained by an analysis of its ash, affords a guide to the manure it should receive; and secondly, that the sulphate or other compound of iron is a desirable ingredient of a fertiliser, because it will give colour to fruit or flowers.

The first opinion is due to Liebig, who, putting aside for a moment the question of the supply of nitrogen, laid down the general principle that, after ascertaining what a given crop is accustomed to take away from the soil, it is only necessary to add the same materials beforehand in order to satisfy all the requirements of the plant. Now, such a point of view is at first sight eminently logical; so conformable, indeed, to our ways of thinking that it has taken 20 or 30 years of experiment and hard controversy to demonstrate its insufficiency; in agriculture the idea has practically disappeared, but in horticultural matters it is constantly recurring, owing to the lack of systematic experiments on the nutrition of garden plants. The cardinal defect of Liebig's theory is that it takes no account of the soil; it might be true if one started to grow a plant in a pot of pure sand containing no nutriment but that which one added to it, but since the plant is placed in soil containing enough food for at least a hundred crops, though mostly in a more or less dormant condition, manure is only really wanted to make good certain deficiencies which are special to the soil and the crop, and these can only be ascertained by actual experiment. Different plants have very different powers of getting hold of particular elements of nutrition, and experience shows that the analysis of the ash of the plant does not enable one to predict in which direction the difficulty will lie.

We must draw our examples from farm crops, because it is only in regard to them that there is a sufficient weight of experimental evidence, and we will simply instance Wheat and Barley among cereals and Turnips and Mangolds among root crops. In the growth of Wheat it is very rarely that any other manure than a nitrogenous one will be required; nitrogen is what Ville calls the dominant for Wheat, and all field experiments, confirmed by the working experience of two generations of farmers, have demonstrated that under normal conditions, if Wheat be supplied with from one to two hundredweight of nitrate of soda or sulphate of ammonia, no profitable increase of crop will be obtained by adding phosphates or potash salts. Yet the analysis of the Wheat plant does not show that it takes much nitrogen from the soil; in fact, it takes more potash; only under the usual conditions of Wheat-growing does the plant find a special difficulty in making use of the reserves of nitrogen in the soil. As far as the ash goes, Barley has much the same composition as Wheat, yet Barley requires much less nitrogen than Wheat, and it is very desirable to supply it with some phosphoric acid. The analysis of Swede Turnips would show that the crop takes away from the soil about 100 lb. per acre of nitrogen, 30 lb. of phosphoric acid, and perhaps 120 lb. of potash; yet there cannot be a shadow of doubt but that the proper manuring for a Turnip crop is primarily 60 to 80 lb. of phosphoric acid, then from 10 to 20 lb., but not more, of nitrogen, and only potash in rare cases. Mangolds do not differ greatly in composition from Swedes, yet Mangolds must be manured with nitrogen and potash, phosphoric acid counts for very little, and may often be omitted. Now, these are facts which have been demonstrated to weariness; they may be paralleled for Clover, for Potatos, for Beans, and for all our other farm crops; they form the basis of the practice of farmers in every civilised country. And yet Liebig's theory—fallacy, we prefer to call it—still is supposed to hold for garden plants, and Dr. Griffiths' book is made up of a series of analyses of the ash of shrubs—analyses which must have cost him endless labour—and recommendations of manure mixtures based on those analyses. We will not labour the point, we will only repeat that in whatever instance the plant itself has been asked by systematic experiment what kind of food it wants, what elements of nutrition it will be grateful for, the answer has borne no relation to the comparative richness or otherwise of its ash in those elements, hence we conclude that an analysis of the plant can afford no guide to its appropriate manuring, and that Griffiths' toils are essentially useless for the purpose to which he devotes them.

Now let us turn to the iron question; it has always been recognised that the rich, red sands and loams of Hereford and neighbouring counties give rise to highly-coloured fruit and brilliant flowers; Tea Roses, in particular, have been thought to take on a special richness of colour. As these red soils owe their colour to oxides of iron, and as iron is known to be essential to the formation of chlorophyll and the red material in animal blood, it seemed a natural step to conclude that an exceptional amount of iron in the soil accounted for the brilliancy of colour in its products. But the least examination will show how very defective the chain of reasoning is, and whatever experimental evidence exists is entirely adverse to the view that the heightened colour is to be attributed to a direct effect of the iron upon the plant. In the first place, however great the part it may play, the amount of iron taken up from the soil is very small, 4 or 5 lb. per acre at the utmost, whereas the amount present in the soil is enormous, 20,000 to 30,000 lb. per acre in the top 9 inches only of soil, and that, too in forms which could easily be appropriated by the plant if it wished to obtain more.

Secondly, the red soils in question are not, in fact, exceptionally rich in iron; most soils—and we have the analyses of many scores before us—yield from 2 to 3 per cent. of oxide of iron, but the red soils from the old or the new red sandstone formations which have come under our review, contain rather less than usual. The conspicuous colour may be due either to a slight difference in the mode of combination of the iron, or to its prominence when spread over a somewhat coarse-grained soil, which exposes a comparatively small surface.

Furthermore, we are acquainted with one or two soils derived from the marlstone, which contain altogether exceptional amounts of iron, at least ten times as much as usual, yet these soils give rise to no exceptional colour in fruit or flowers. Lastly, there is but little experimental evidence in support of the connection between iron and colour, in the majority of cases at any rate; we have in our mind a series of experiments upon dwarf Apple trees in large tubs, where, year after year, the Apples

* *Manures for Fruit and other Trees.* By A. B. Griffiths, Ph.D., pp. 264, xxii. London: Sutton, 1908.

supplied with sulphate of iron were the greenest of the series. There is on record also a series of experiments made by Mr. H. H. Cousins at Wye College for the National Carnation Society, in which the use of sulphate of iron made no difference to the colour of yellow-ground fancies. There was some evidence that a scarlet self did not show white flecks so readily in sunshine when they had received iron, but the experiments were not pushed far enough to exclude a possible secondary cause. The action of soluble iron salts upon garden plants is worthy of further investigation, but the evidence, as far as it goes, is all adverse to the supposition that high colour is necessarily or habitually correlated with an abundance of iron in the soil.

We have dwelt at some length on these two matters, namely, the relation supposed to exist between the ash and the manure appropriate to a particular plant, and the supposed connection of iron with the colour of fruit, for we regard the one as a fallacy, and the other as an unproven hypothesis.

OUR SUPPLEMENTARY ILLUSTRATION shows a bed of Campanula persicifolia in the Botanic Gardens at Kew. The Campanulas, or Bell Flowers, are amongst the most valuable of garden plants, not only on account of their floriferous character, but also because of the ease with which they are cultivated. The genus Campanula is a very large one, and the enumerations of the species and synonyms occupy no fewer than 20 columns in the *Index Kewensis*. Amongst so wide a range are found varieties suitable for all quarters of the garden. Some are showy border subjects, and of these the two best known are C. persicifolia and C. pyramidalis, both of which are represented in gardens by several excellent varieties. The flowers of C. persicifolia are very broadly campanulate, and although the type colour is blue, there are shades intermediate to white; and some of the varieties possess double flowers. The culture of this Campanula is easy, but it undoubtedly thrives best and blooms most freely on chalky soils. Its propagation is readily effected by seeds, which may be sown out-of-doors in a shady border, either in March or when the seeds are ripe in August; it will also reproduce itself naturally from seedlings if the ground about the old plants be left undisturbed. Propagation may also be effected by means of young shoots inserted in March or April. These should be placed in a light soil in a cold frame. It may also be increased by division of the root stock. The double forms are very beautiful, and these appear to have been raised many years ago, for, according to the *Botanical Magazine*, in the year 1798, the double varieties had become so common as to almost usurp the single varieties from gardens. The older of the double white and double blue forms are known respectively as C. p. alba fl. pl., and C. p. cærulea fl. pl. On June 19, 1900, a beautiful double white variety was exhibited by Messrs. T. S. WARE, LTD., Feltham, at a meeting of the Royal Horticultural Society under the name of C. p. Moerheimei. This plant was figured in our issue for June 30, 1900; the flowers, which are reproduced a natural size, average from 2 to 3 inches in diameter. Another variety of C. persicifolia was illustrated in the *Gardeners' Chronicle*, October 23, 1883, under the name of C. p. Backhouse's variety.

THE NATIONAL ROSE SOCIETY.—The great summer exhibiton of this flourishing Society will again be held in the Botanic Gardens, Regent's Park, the date being Friday, July 3. The classes are more numerous than ever, and only fall one short of one hundred. There are 13 new classes added this year, four in the open classes and nine in those devoted to amateurs. An exhibition of Roses will be held under the Society's auspices in the Royal Botanic Gardens (The White City), Manchester, on Tuesday, July 21. The autumn Rose Show will be held in the Royal Horticultural Hall, Vincent Square, Westminster, on Thursday, September 17.

ASPARAGUS SHOW AT EVESHAM.—The twelfth annual show of Asparagus was held in the Town Hall, Evesham, on Monday, the 1st instant, the proceedings being opened by the Mayor of that town. The whole of the exhibits are annually sold by auction at the close of the exhibition, many of the buyers of the best exhibits being Covent Garden salesmen. The heaviest bunch of 120 "heads" weighed 27 lbs. 4 ozs., and sold for 46s.: this was grown by Mr. FAULKNER, of Pershore, who usually obtains the prize offered for the heaviest bunch. The bunch, to which was awarded the 1st prize for size and quality, was grown by Mr. G. KNIGHT, of South Littleton: it weighed 19 lbs. 11 ozs., and was sold for 38s. Other weights and prices were:— 19 lbs. 4 ozs., 22s. 6d.; 20 lbs. 14 ozs., 23s. 6d.; 18 lbs. 12 ozs., 25s. 6d.; 17 lbs. 7 ozs., 21s. 6d.; 13 lbs. 12 ozs., 20s. 6d.; 18 lbs. 12 ozs., 20s. Only three bunches were sold for less than 6s. per bunch. There are about 5,000 acres of land devoted to Asparagus culture within a radius of six miles of Evesham, and still more is being planted each year. One grower is planting 20 acres with Asparagus this season.

BRITISH GARDENERS' ASSOCIATION.—A meeting of the London branch will be held at Portland Road Station, on June 13, at 3 p.m., when Mr. HAWES will conduct the party to the Regent's Park and Royal Botanical Gardens. Gardeners, whether members of the association or not, are invited to attend this meeting.

R.H.S. GARDENS GUILD.—We are asked to announce that the first annual general meeting will be held on Wednesday, July 8, the second day of Holland House Show, at 7 p.m., in the CHARLES DICKENS Rooms, Carr's Restaurant, Strand. It is particularly hoped that all who have at any time been students or employees in the R.H.S. Gardens at Chiswick or Wisley will endeavour to be present, and will give early notice of their intention to the acting hon. secretary, Mr. R. WALLIS, R.H.S. Gardens, Wisley, Ripley, Surrey.

FLOWERS IN SEASON.—A selection of flowering shrubs has been sent us by Messrs. JAMES VEITCH & SONS, LTD., from their Combe Wood Nurseries, Kingston Hill. All are from the open grounds, and they mainly represent improved varieties of well-known subjects. The Lilacs include the exquisite double white variety named after Mme. Lemoine. Guelder Roses include the globose-flowered Viburnum plicatum, with inflorescences of snowy whiteness, and the flat corymbose heads of V. tomentosum var. Mariesii. The Mock Orange (Philadelphus) is greatly improved in the variety Boule d'Argent, the shoots having axillary racemes of white, fragrant flowers. Another, P. purpurea maculatus, is not so crowded with blossoms, but a tinge of crimson at the base of the petals is an additional attraction, and against this colouring the yellow stamens are prominent. Ceanothus Veitchianus has deep blue flowers, against which those of C. thyrsiflorus appear pale. The Deutzias are all floriferous subjects, D. discolor and D. gracilis being both valuable garden plants. The former is represented in a large-flowered form, labelled D. d. grandiflora, the latter by D. g. venusta. Purple, yellow and white-flowered varieties of Cytisus, the showy Weigelas, of which W. rosea is now so prominent a feature in suburban gardens, a double-flowered Wistaria, and many others form an interesting collection.

HORTICULTURAL CLUB.—The next house dinner of the club will take place on Tuesday, June 23, at 6 p.m., at the Hotel Windsor. Mr. H. HITCHCOCK, of Victoria, Australia, will lecture on "The Development of Gardening in Victoria during Recent Years."

FORCED BULB SHOW.—We are asked to state in connection with the special prizes for Hyacinths and Tulips to be competed for on Tuesday, March 9, 1909, at the meeting of the Royal Horticultural Society, that the Council would be glad if this date could be made a general one for the exhibit of collections of forced spring bulbs, specially with a view to showing which varieties (of Daffodils for instance) are best suited for forcing. The Council invite the exhibition of small collections from amateurs as well as from the trade.

FRENCH HORTICULTURISTS IN LONDON.—A party of excursionists, limited to 200 members and friends of the National Horticultural Society of France, will visit London on the 22nd inst., and return to France on the 29th. The excursion will include a visit to the Franco-British Exhibition for the flower show of the 24th, a visit to Kew Gardens, Windsor, and the principal parks and nurseries in and around London.

M. PHILIPPE DE VILMORIN.—We observe with pleasure that this eminent French horticulturist has recently been appointed a Chevalier of the Legion of Honour. This gentleman has done much for international horticulture, and the honour is well deserved.

PRESENTATION TO PRESIDENT FALLIÈRES.—On the occasion of the recent visit to London of the President of the French Republic, a committee was formed, of which Sir ALBERT ROLLIT was appointed chairman, to make a presentation to M. FALLIÈRES, in the name of British members of the Legion of Honour and other French Orders. The presentation consisted of a gold and silver casket containing an illuminated address on vellum, and the presentation was made to M. FALLIÈRES by Sir ALBERT ROLLIT at St. James's Palace. Many gentlemen connected with literature, art, and science were among the number of subscribers, and it is interesting to note that English horticulture was also represented, for in the list we observe the names of Sir ALBERT ROLLIT, Mr. GEORGE STANTON, Mr. MARTIN SUTTON, and Mr. HARMAN PAYNE.

UDO OR OUDO.—Mr. J. G. BAKER informs us that this vegetable, to which reference was made on p. 317, consists of the young blanched shoots of Aralia cordata, a native of Japan. It has long been cultivated by the Japanese as a vegetable. It was originally described by THUNBERG in 1784, and was re-described and figured by SIEBOLD and ZUCCARINI in 1835 under the name of Aralia edulis. There is a full account of it by Mons. EDOUARD ANDRÉ in *Revue Horticole*, 1896, p. 55. This nurseryman cultivated it in his garden in Touraine, and warns us that, as a vegetable, it possesses a resinous flavour that would not be palatable to everyone. It can easily be procured from the Japanese nurserymen.

GARDEN COMPETITION AT CUPAR.—A very interesting gardening competition in Cupar, Fifeshire, held under the auspices of the Edinburgh and East of Scotland College of Agriculture and the Fifeshire Education Committee, has just been completed by the issue of the prize list. A class was conducted by Mr. G. P. BERRY, and at the close a paper was set. The competition was in three sections—one for practical and market gardeners, another for amateurs and cottagers, and a third for ladies. In the practical section the competitors were asked to describe the best method of laying down in the open an acre of fruit trees—Apple, Pear, and Plum—with under-planted small fruit, giving the most up-to-date cultural treatment over a period of six years. Also, the most approved cultural details in the growing of the first early Potatos, early and late Cauliflower, and Onions for bulbing purposes in a private garden. The amateurs' and cottagers' problem consisted of the laying-out of a small piece of ground as a cottage garden from old pasture land, including soil, working, manuring, cropping, propagating, planting, and pruning; also, the best culture for Roses in a small garden. The ladies were asked to give their views on the history of the Sweet Pea, emphasising its adaptability for decorative purposes inside the villa and mansion, and their ideas with regard to arrangement of flower foliage in vases and for table decoration were also asked. A large number of papers were sent in, and the premier places were taken as follow:—Practical and market gardeners, 1 (Silver Medal), DAVID DALRYMPLE, gardener, Dura House; 2, PETER WALKER, gardener, Cairnie. Amateurs and cottagers, 1 (Silver Medal), W. OLIPHANT, Bonnygate; 2, CHARLES STORRAR, architect, East End Park. Ladies, 1, Miss INNES, Rosemount; 2, Mrs. E. M. LENNOX, Castlefield.

NEW BOTANIC GARDEN IN AMERICA.—The large amount of money that has been given for educational purposes in America has provided for the establishment and endowment of universities in many parts of the States, and in most of them the claims of botany are recognised in the provision not only of a chair for the science, but also of a suitable botanic garden. The Johns Hopkins University, at Homewood, Baltimore, has, according to *Gardening* (Chicago), made provision for a new botanical garden, which is to be under the care of Prof. D. S. JOHNSON. It is contemplated to commence at present with a biological garden and one greenhouse for biological work. Later on there will probably be added a systematic garden of about two acres. In addition to these, plants, trees, and shrubs of botanical and ornamental value will be planted on suitable sites in Homewood Park conforming to the general landscape plans. Mr. WM. H. WITTE is to be the garden superintendent.

FIG. 175.—IRIS × AMETHYST: FLOWER VIOLET IN VARIOUS SHADES.

A NEW JAPANESE ROSE.—Rosa yedoensis of MAKINO has now been brought into cultivation. It has the foliage of Rosa rugosa, with an inflorescence like that of Rosa multiflora, with numerous rather small pink flowers. Plants of it may be procured through the Japanese nurserymen.

STREET TREES.—Although there are so many handsome trees suited for town planting, we are accustomed to see the same species planted with almost monotonous frequency. One of the reasons given for this is that other suitable trees are not procurable in quantity from British nurserymen, but if a demand existed for them, surely the nurserymen would not be slow to propagate and stock them. In the First Garden City at Letchworth the streets have been planted with trees that are not commonly used for the purpose, and which are found there to be equally as valuable as the more common Plane, Horse Chestnut, and Sycamore. Fraxinus monophylla has proved to be an excellent subject at Letchworth if given a fairly deep root run. Pyrus Aria is valuable for planting in windy and exposed streets. Many forms and species of Acer have been employed. Of these the gardener, Mr. F. J. COLE, has sent us examples of A. Pseudoplatanus Leopoldii, A. P.-p. lutescens, A. platanoides digitatum, A. p. Schwedleri, and A. dasycarpum.

CULTIVABLE LAND FOR THE USE OF THE POOR.—The Poor Law administration of Posen have created a new institution. Town land suitable for cultivation and letting is divided into sections of 200 square metres, and let to deserving poor persons for gardening purposes. The annual rent for such small areas is fixed at two shillings. The authorities hope, from this arrangement, to improve the domestic condition and health of the poor. It is also hoped to foster an educational purpose and stimulate the alms receivers, who by means of *petite culture* will be working out a part of their subsistence.

BIOLOGICAL PROFESSORSHIP AT CAMBRIDGE.—Mr. W. BATESON, F.R.S., has been appointed to the Professorship of Biology founded at Cambridge about five years ago by an anonymous donor. Professor BATESON is well known as one of the leaders in the experimental study of heredity at the present time, and his appointment will strengthen the University of Cambridge, which is already doing so much to further the advancement of biology, both pure and applied. Our readers will remember that Professor BATESON presided at the third International Conference on Genetics held under the auspices of the Royal Horticultural Society in 1906.

FRANCO-BRITISH EXHIBITION.—Mr. J. JAQUES, superintendent of the horticultural shows at the Franco-British Exhibition, asks us to state that the flower show to be held on June 24-26, will be arranged in the spacious Palace of Music, adjoining the Court of Honour, the most prominent and central position in the exhibition. No. 3 gate in Wood Lane will be the most convenient entrance for exhibitors' vans, &c.

IRIS × AMETHYST.

THIS hybrid (see fig. 175) is the result of inter-crossing Iris sindjarensis and I. persica purpurea, the progeny partaking largely of the habit and floriferous nature of the first-named parent. The colour is violet, in pleasing shades, the deepest colour being found in the falls. The upper portion of the blade renders this part of the flower very conspicuous. Iris × Amethyst was shown at the meeting of the Royal Horticultural Society on March 31 last, when the Floral Committee granted it an Award of Merit.

AMERICAN GOOSEBERRY-MILDEW.

PRECAUTIONS FOR SUMMER AND AUTUMN.

THE Board of Agriculture and Fisheries desire to call the attention of fruit growers and horticulturists generally to the fact that the operations now being carried on against the disease of Gooseberries and Currants, known as American Gooseberry-mildew, cannot be expected to prove successful unless all growers are prepared to give active and vigorous assistance in checking the spread of the disease. The disease exists in two forms known as the winter and summer stages. The summer stage occurs on Gooseberry bushes from May or June until November, or even later if the season is mild, and in this stage the disease is highly infectious. The following suggestions are made for the purpose of assisting growers whose gardens have been affected, and all other persons who have reason to fear infection, to check the further spread of this dangerous disease:—

1. Those who do not already possess the Board's leaflet describing American Gooseberry-mildew, should send an unstamped postcard addressed to the Secretary, Board of Agriculture and Fisheries, 4, Whitehall Place, London, asking for Leaflet No. 195, which gives full particulars of the appearance of the disease and of the time when it may be expected.

2. A supply of liver of sulphur, for spraying purposes, should be procured. This will cost from 4d. to 7d. per lb., according to the district and the quantity purchased, but if 14 lb. or more are bought the price should not exceed 6d. per lb. The liver of sulphur must be kept in air-tight tins or in well-corked bottles or jars, since if exposed to air it soon becomes useless, while if stored in airtight vessels it will keep good for a long time. Liver of sulphur is one of the most useful fungicides, and if no Gooseberry-mildew should appear, it can be employed for spraying other plants, so that fruit growers will lose nothing by keeping a supply in readiness. On the other hand, if liver of sulphur is not at once available when American Gooseberry-mildew appears, crops may suffer severely before the remedy is obtained.

3. Arrangements should be made for the purchase or use of a sprayer. Hand sprayers of the syringe pattern, suitable for small gardens, may be purchased for from 7s. 6d. to 15s., and knapsack spraying pumps for from 35s. to 40s.

4. Gooseberry bushes in a district where disease exists, or has recently existed, should be carefully examined every day, as the disease passes into the summer stage and develops very rapidly. On discovering disease in his garden a grower should proceed as follow:—

(*a*) The bush should be marked so that it may be readily found, but should not otherwise be interfered with. The disturbance of a bush would be likely to spread the disease.

(*b*) A wash should be made up consisting of liver of sulphur and water in the proportions of 1 lb. to 32 gallons. The affected bush and neighbouring bushes should be drenched with the wash. If a sprayer is not immediately available, a watering can should be used.

(*c*) If the liver of sulphur wash comes in contact with the mildew, the fungus is destroyed; but it is almost certain that some diseased parts will escape. As soon, therefore, as the bushes are dry, they should be carefully examined, and any twigs, leaves, or fruit showing signs of disease should be removed and burnt.

(*d*) When an infected twig is found on a bush, the probability is that many other twigs on the same bush, and on other bushes near to the diseased bush have become infected. As soon, therefore, as the diseased twigs, leaves, &c., have been destroyed, the bush itself and bushes in contact therewith should be destroyed, or the wood of the current year on a diseased bush and on adjacent bushes must be removed and destroyed, otherwise this wood may become infectious in the course of a few days, and disease will be carried through the garden on the clothing of labourers, on baskets, and by other means. *If a bad case of disease occurs, much the best plan is to root up and destroy the bushes, after spraying.*

(*e*) The ground beneath a diseased bush must be sprayed with a wash containing not less than 1 lb. liver of sulphur to 24 gallons of water.

5. When the disease has thus been dealt with, all Gooseberry and Currant bushes in the garden should be sprayed with a solution of 1 lb. liver of sulphur in 32 gallons of water. This treatment should be repeated at intervals of 10 days to a fortnight during the summer months. If rain should fall before the spray has had time to dry on the bushes, the work should be repeated as soon as practicable.

6. For spraying in the summer months there is no material so efficient as liver of sulphur, and the Board do not at present recommend anything else. The Board have not formally approved spraying materials prepared by private firms, but in those cases in which County Councils have asked for guidance in approving proprietary sprays, the Board have recommended for approval sprays which, when prepared for use, contain not less than 1 lb. of liver of sulphur to 32 gallons of water.

7. In the autumn, when bushes have nearly finished growing, copper sulphate, instead of liver of sulphur, may be used for spraying, at the rate of 1lb. copper sulphate to 16-20 gallons of water; but copper sulphate, although cheaper and very effective in destroying mildew, should not be used early in the season as it would injure the crop. Liver of sulphur will not damage the fruit.

8. The discovery of the mildew should at once be reported to the Inspector of the Local Authority, but the spraying of the bushes should on no account be delayed. Prompt action on the part of Gooseberry growers may save them and their neighbours a good deal of trouble. *T. H. Elliott, Secretary, Board of Agriculture and Fisheries, 4, Whitehall Place, London, S.W. May 23, 1908.*

LAW NOTE.

LIMITED LIABILITY.

IT may be well to remind those commercial firms who carry on business as private limited companies that it will be to their interest to pass certain resolutions during the present month if they have not already taken steps to comply with the provisions of the Companies Act, 1907. The principal provisions of this Act will come into force on July 1 next, and special privileges are given to what are defined by the Act to be "private companies"; these privileges include, for instance, exemption from the necessity of filing at Somerset House an annual balance-sheet containing such particulars as will disclose amongst other things the general nature of the companies' assets and liabilities and how the value of the fixed assets is arrived at. As this balance-sheet will be open to the inspection of any person who chooses to call at Somerset House and pay a search fee of 1s., private limited companies will naturally prefer to avail themselves of the exemption from complying with these requirements. A limited company which desires to become a private company within the meaning of the Act cannot, however, achieve its purpose merely by alleging that it comes within this definition. For the purposes of the new Act the expression "private company" means a company which by its article (a) restricts the right to transfer its shares; (b) limits the number of its members (exclusive of persons who are in the employment of the company) to 50; and (c) prohibits any invitation to the public to subscribe for any shares or debentures of the company. These resolutions have to be passed at a general meeting of the shareholders, and confirmed at a subsequent general meeting which has to be held not less than 14 *clear* days and not more than one month after the first meeting. It should be noted further that, unless the company's Articles of Association otherwise direct, at least seven clear days' notice of a meeting should be given to shareholders, and in computing this period the day on which the notice will reach the shareholder in the ordinary course of post and the day fixed for the holding of a meeting should not be included. It will be seen therefore that companies which desire to be recognised as private companies before the new Act can inconvenience them, ought to take the necessary steps at the earliest possible moment. With regard to private limited companies about to be formed, it is desirable that the actual registration should take place before July 1 next, as various harassing rules and requirements, which will come into force on that day in connection with the registration of companies, will thus be avoided. In considering the question of limited liability, it may be noted that surprise is frequently expressed at the fact that the provisions of the Limited Partnerships Act of 1907 have not been more generally utilised in this country. It will be recollected that under this Act it is possible for a person to invest in a commercial firm by way of "sleeping partnership" without becoming liable for any part of the firm's debts and liabilities beyond the amount which he has invested in the concern. In other words, the sleeping partner stands to lose his capital in the event of disaster, but runs no further risk. In certain cases this is obviously a convenient mode of investment, but from the investor's point of view it has to be borne in mind that there are various restrictions upon the rights of a sleeping partner who avails himself of the benefits of this Act. In the first place, it is impossible to avoid a certain amount of publicity, as particulars of the transaction have to be registered at Somerset House. Secondly, a sleeping partner cannot on any account take any part in the management of the partnership business with the exception that he may "inspect the books of the firm and examine into the state of the business and advise with the partners thereon." Thirdly, he cannot withdraw any part of his invested capital during the continuance of the term of partnership agreed upon, and if he does so he will be liable for the debts of the firm to that extent. Fourthly, the active partners may introduce a new partner into the business without the consent of the limited partner. Fifthly, the death or bankruptcy of a limited partner will not operate to dissolve the partnership before the expiration of the term of partnership, so that his assets may be thus locked up for a considerable period after death. There are, in addition, certain further provisions to be borne in mind by an intending investor, but want of space forbids detailed explanation of them in these columns. It will be seen, however, that the rights of a person investing money in a limited partnership are not even so great as those of a shareholder in a private limited company. The shareholder, even if not also a director, has the right to attend at general meetings and to give his vote on any matters which may be proposed for resolution, and in this sense he is able from time to time to take at least some active part in the management of the concern. Again, a person who invests money in the debentures of a limited company stands practically in the position of a mortgagee, and is entitled to be repaid his capital out of the assets before the general creditors of the company receive anything. His position is therefore far superior to that of a limited partner who is not entitled to recover any portion of his invested capital until all the debts and liabilities of the firm have been provided for. It is probably for these reasons that the Limited Partnerships Act has not yet been generally utilised in this country, although in Germany and other foreign countries somewhat similar methods have for some time past been successfully adopted in commercial circles. Looking at the matter, however, from the point of view of the borrower and not from that of the lender, there is a good deal to be said in favour of the Limited Partnerships Act. It enables the trader to obtain an introduction of fresh capital into his business without incurring the expense and trouble involved in turning a business into a private limited company, while at the same time the regulations are somewhat less troublesome than those which have to be observed by firms registered under the Companies Acts. *H. M. P.*

THE APIARY.

Queens and supposed queenlessness.—Some weeks ago I had to make an examination of a stock and found it in a most flourishing condition; eggs and brood were plentiful; in fact, eight frames out of the ten were filled. Just over a week ago some frames of brood were needed for a weaker hive, and I naturally concluded I might borrow a frame of brood from this hive. My surprise may be imagined when I noticed that there was only sealed and hatching brood, with plenty of vacant cells. The frames were carefully searched for a queen, but none was to be discovered, and I came to the conclusion that the hive was queenless through some accidental cause. At the same time, I was reluctant to accept this verdict, and promised to visit the apiary a week later. How different things were then! Nearly every vacant cell was occupied and the queen was discovered without any difficulty. Those who discover a similar condition must therefore not be in too great a hurry to give a new queen to such a colony. I can only suppose that the queen had temporarily ceased laying because of the excessively cold weather.

Adding supers.—When the upper cells in the brood chamber have a white edge, that is a sign that we may add room for storing above. If it be intended to use sections principally, then it will be an advantage if shallow frames containing drawn-out comb be first added, for bees are very reluctant to store in sections.

Swarms.—We may expect swarms any time, and it will be well to keep a sharp look-out for them between 9.30 a.m. and 3.30 p.m. Some swarms, especially on hot days, do not attempt to settle near the hives. It is a good plan to have at hand a bucket of water and a syringe, as well as the skep and cloth ready for hiving. Should it be thought that the bees have decided to leave the apiary, a few sprays from the syringe in their midst will soon cause them to settle, as the bees imagine it to be a shower of rain. When the bees have clustered, a sprinkling of cold water will cause them to fall in a more solid mass into the skep, held underneath to receive them. When the major portion of the swarm has been shaken into the skep, overturn the skep on the cloth which has been previously spread on the ground to receive stragglers which missed the skep, and in order to facilitate matters, keep the skep well raised by placing a stone under one side. Sometimes bees settle in awkward places. After an unfavourable spring some years ago, I was called out to see to a swarm in a hedge, as the bees were dangerous to passers-by. The bees came from a hive which had little food in it, and, consequently, they were not well fed with honey, as they usually are, and were, in consequence, in a very bellicose state. The hedge was of thick thorn, so I placed the skep on the top above the swarm, which was in the centre of the hedge, and, having filled my smoker with plenty of fuel, I soon dislodged and hived them. Sometimes they settle on the trunk of a tree and even on a wall. A dust-pan and a stout quill will be best to dislodge them. Use the quill with great care, or the bees will be irritated, and on no account use a brush. After 6 p.m. the bees can be removed to permanent quarters. Sometimes the bees will not settle in the skep from some cause or other, even when we know that the queen is safely hived. When this is the case, take a frame containing brood in all stages and hive them at once in permanent quarters with this frame in the centre, for bees will rarely desert brood.

Brood frames.—Bees seldom build drone comb during the year in which they were taken as a swarm, and as they are prepared for extensive comb building, it is wise to only fix starters in the brood frames, and to place on sections or shallow frames above with full sheets or drawn-out comb. These latter provide storing accommodation for the honey which they gather, and thus prevent the bees from using the brood chambers for any other purpose than brood raising. *Chloris.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

THE TEMPLE FLOWER SHOW.—*A Fellow* on p. 373 draws attention to what has undoubtedly been in the minds of many other persons who have visited the Temple Flower Show in recent years. There is no doubt that this show has been of infinite service to the R.H.S., for it has helped the Society to secure large numbers of members and has added materially to the Society's prestige. In the early days, the Temple Gardens were probably all that could then be desired, but, like many other things, the exhibitions have outgrown their quarters, and the difficulty is to find another equally suitable site. Whenever I go to Paris and see the splendid site comprising the two large greenhouses on the Cours de la Reine, and the grounds adjoining in which the National Horticultural Society of France has held its spring and autumn shows since 1900, I ask myself where in London could similar quarters be found for our great horticultural exhibitions. These greenhouses at Paris will be demolished after November next, and then the French Society may possibly be in some difficulty as to a place for its future shows. The Temple Gadens are central. That is an immense advantage. No flower show to be successful in London can be held elsewhere than in a central and easily-accessible spot. But even if that be found, there still remains the great disadvantage of having to hold the shows in tents instead of in a pemanent glass structure. On reading *A Fellow's* communication, it has occurred to me that one of the difficulties in the matter is the short length of time the Temple Show is open to the public. The Paris Show is open for a week, and the price is gradually reduced as the time draws to a close. The Temple Show is open for three days only. If it could be extended over another day with, say, a sixpenny admission, more visitors might be induced to attend, the pressure that exists at present might be reduced, and the funds increased. The Temple Show has now become a fixed institution and an annual society function, and there would be some danger in moving it anywhere, but the fact remains that it has practically outgrown its present quarters, that the exhibits are not presented to the public view to the best advantage, and that visitors now attend in numbers so great that there is very little comfort for them in making a tour of the show. One of the great features of the Paris site is the fine promenade leading from the entrance to the greenhouses. Vast number of visitors can, and do, overflow into this promenade when the pressure inside becomes severe. Seats are provided, and the numerous exhibits outside afford ample means for those out-of-doors to enjoy themselves. *A Fellow* reminds us that so long as tents of the ordinary type are used they admit of little variation on stereotyped methods. This, of course, is so: a table in the middle, a table round the sides, with a narrow path between is the inevitable arrangement, instead of numerous wide paths in different directions to relieve the pressure, as is customary at the Continental shows. Unfortunately for the present no site can well be found that will pay simply to hold flower shows, any one at all suitable would have to be utilised for other purposes as well. *C. Harman Payne.*

EFFECT OF SPRING FROST IN WESTERN SCOTLAND.—As the frost in Easter week, 1908, has proved more destructive in the south-west of Scotland than any we have experienced since the memorable May frost of 1907, it may be useful to record the behaviour of some of the tenderer forms of exotics. The thermometer at Monreith registered 14 and 12 degrees of frost (viz., it fell to 18° and 20° Fahr.) on two successive nights, which had serious consequences upon such plants which the foregoing warm weather had encouraged into forward growth. Among Himalayan Rhododendrons injury was very general. The only species that escaped unscathed were R. Hodgsonii, Fordii, niveum, cinnabarinum, Smirnowi fulgens, and a few plants of R. arboreum. Most of the R. arboreum had their leading buds destroyed; so had R. Falconeri, R. eximium, R. barbatum, R. Aucklandii, R. exioniense grande (argenteum), R. Kewense, R. glaucum, R. Luscombianum, R. Thomsonii, Beauty of Tremough, Gill's Triumph, &c. R. campanulatum suffered partially. None of these was killed, and all are now pushing forward secondary shoots, but the effect upon next season's display remains to be proved. Of the early-flowering hybrids, of course, the blossom was ruined, but the new growth does not seem to be checked, and the later-flowering Rhododendrons, as a rule, are peculiarly fine this season. Pink Pearl, George Hardy, the Queen, and Lawson's hybrids × Fortunei are specially good. The following shrubs have not been injured, and are now (June 6) in full bloom:—Solanum crispum, Sophora tetraptera, Grevillea rosmarinifolia, all on walls; Buddleia globosa, in the open, had not a leaf damaged, but B. variabilis was cut back a long way. Desfontainea spinosa and Tricuspidaria lanceolata, both in the open, were badly browned, all the flower-buds of the latter falling off. Deutzias have been badly injured, but among the Berberis, only B. Knightii was hurt, and that not badly. Eucryphia pinnata and cordifolia, Coriaria torminalis, Olearia macrodonta, O. stellulata, O. Gunnii, and O. nummularia; Illicium religiosum, Chamærops excelsa, Escallonia macrantha, E. exoniensis, E. × Langleyensis, E. Phillipiana, and E. rubra; Choysia ternata and Griselinia littoralis have not been injured, except slightly where exposed to the wind, but Olearia nitida and Hypericum patulum are badly cut, as are also Fuchsia Riccartonii, Fatsia japonica, Indigofera Gerardiana (30 years old), Rosa bracteata (on a wall), Schizophragma hydrangoides, and, strange to say, the common white Jasmine. Raphiolepis japonica is killed outright, as are many plants of Cordyline australis, although others on poorer soil have escaped. Azara microphylla and Ceanothus azurea (on a wall) are unharmed. Among forest trees little harm has been done. Larix leptolepis was already in leaf, yet suffered not at all either in the woods or in nursery beds; Picea morinda and the Scots Pine are the only evergreen Conifers browned, but both are now growing strongly. The Chilian Fagus obliqua, the foliage of which expands early, had its young growth killed back, which bodes unfavourably for its future as a British forest tree. Among plants of humbler growths, the following may be noted as being none the worse for the severe weather: Crinum Moorei and C. Powellii, Agapanthus Moorei, Romneya Coulteri, Incarvillea grandiflora and Primula Cockburniana, but Gerbera Jamesonii, having stood out the winter of 1906-7 in a wall garden, put in no appearance this spring. The Androsaces differed. A. carnea, A. Vitelliana, and A. villosa were unharmed, but A. sarmentosa, A. lanuginosa, and A. foliosa were frosted back to their centres, whence they are now springing afresh. None of the Campanulas or Wahlenbergias suffered, except a few plants of C. fragilis (Barrelieri), but even of this delicate species most are now fresh and green. To revert to shrubby growths, in a considerable collection of Cistus only two or three plants of C. florentinus, C. undulatus, and C. cretieus succumbed. Embothrium and Davidia are almost scatheless, so are Erica arborea, E. lusitanica, Piptanthus nepalensis, and Nandina domestica, but a young plant of Rhus cotinoides was killed. In a neighbouring garden Callistemon rigidus (?), which has grown against a wall for more than 25 years, protected by a mat in winter, is growing strongly and bearing many flower-buds. *Herbert Maxwell, Monreith, June 6.*

THE BUSHEY PARK CATASTROPHE.—It was a swift tornado, almost momentary in its duration, which swept over the well-known Bushey Park, Teddington, on the evening of the 1st inst., and left behind it such evidence of devastating force as English people can rarely see. The catastrophe is no common one, seeing that Bushey Park is one of the nation's open spaces, and the grand old avenue of Horse Chestnuts and their background of double rows of tall Limes one of the greatest attractions to the visitors to the Park and Hampton Court Palace. If there is in connection with this destruction anything to be thankful for, it is that the tornado spent its force on the end of the great avenue farthest from the Palace, rather than near to it. Coming from Richmond Park, the wind passed over low-lying

Kingston, and it drove against the outer or eastern side of the Lime trees, sweeping down scores of these, then the next line of Lime trees and later the Chestnuts, creating, in space of time, too brief to estimate, a terrible slaughter of trees that had been planted in the days of William and Mary, and for generations had lifted their lofty heads proudly to Heaven, defying the seasons and storms. Who, seeing this arboricultural wreck, could help exclaiming "How are the mighty fallen!" Whilst the lofty Limes, ranging from 90 to 100 feet in height, had all been torn up by their roots, the Chestnuts had more generally broken off above ground, their huge stems presenting masses of splinters. Not one of the Limes had sent their roots deeper into the sandy soil than 2 feet, hence they had no great grip of the ground. Some Elms, not in the avenue, but near to it, also fell with a terrible crash, and these showed the same root weakness. That very weakness should point its moral to those in authority, if the rest of the noble trees of the famous Bushey avenue, as well as those not less tall, but all too rapidly decaying Limes in Hampton Court Gardens and Park, are to be saved from some similar catastrophe. Had all these been heavily topped or lopped some fifty years ago, how different might have been their case to-day. In the case of those remaining it is not too late to take off some 40 feet from their too lofty and rapidly weakening heads, thus compelling the roots to become more active and the trees to create younger branches. There exist in this country numbers of lofty trees that, like these Bushey Park Limes, have far too poor roothold of the soil, and which may fall preys to a wind storm at any moment. These might all be saved for possibly generations were their tall heads reduced and the stems compelled to clothe themselves with branches lower down. It may be a matter of pride to point to lofty trees that thus lift their tall heads to Heaven, but as the old adage says, "Pride goes before a fall," and if there had been less pride in height and more in density and endurance, which early beheading would have created, then the fall might have been postponed. Many trees have had their lives indefinitely prolonged by early beheading. *A. D.*

BALDERSBY PARK, THIRSK.—Visitors to the York Jubilee Exhibition, to be held on the 17th, 18th, and 19th inst., should take advantage of the opportunity for inspecting the gardens and grounds at Baldersby. The present owner, Mr. Brennand, purchased the estate from Lord Downes a few years ago. In the interval the whole of the glasshouses have been renewed and extensive additions made. No doubt Mr. Hathaway, the gardener, would be pleased to give information as to the best route, and the most convenient time to visit the gardens. *H. J. C.*

THE BEST DAFFODILS.—I think the time has now come when we should have some authoritative list of the best Daffodils in the different sections. In the first instance the R.H.S. Narcissus Committee is the body we might expect to do the work. The list should be divided into the following sections:—The best yellow trumpet varieties for naturalising; the best white trumpets for naturalising; and the best in each other section for naturalising; also the best in each section for market purposes. The best market sorts would be equally useful for the amateur and private gardener, as the best for the market grower must also be the best for all who force Narcissi. So far as naturalising is concerned, there would probably have to be several lists, for different soils vary so much. The number of varieties is now so bewildering that no one can easily select the best for any purpose. In the course of the selection it will probably be suggested that the very worst varieties should be buried at least 10 feet deep! *T. Smith. Newry.*

A VALUABLE HYBRID PÆONY.—Through the courtesy of Mons. René Rouhard, of the nursery of the Museum of Natural History of France, I have been able to see what promises to be a valuable break in Pæony hybrids. In 1900 Mons. L. Henry crossed Pæony "Ville de St Denis" with the new Pæony lutea, and the resulting cross has now flowered for the first time in Paris. It produces flowers both on the terminal and the lateral shoots, thereby following the habit of Pæony lutea. The flowers produced on the terminal shoots are large, well formed, double, and yellow in colour; but that on the lateral shoot is as interesting as it is beautiful. The shape it has assumed is that of a large, double, yellow Begonia, tipped with rose, and on the first examination it can hardly be distinguished in shape from the latter flower. If only this form can be definitely fixed, we shall at once obtain a valuable and original addition, in shape as well as in colour, to our herbaceous Pæonies. The "Jardin des Plantes" is to be sincerely congratulated upon the success of the first attempt of this cross. *R. H. Beamish.*

APPLE CHARLES ROSS.—I was surprised to read, on p. 314, *A Working Grower's* unfavourable report of the cropping qualities of this Apple, for whilst opinions may differ as to its edible quality, this is the first time I have heard or read anything against it as a bearer; with me, it is most prolific, producing fruits on two-year old Paradise trees most freely, and on young standards, grafted on the Crab of only four years' growth; in fact, it bears well when grafted on either of these stocks, and on trees of every shape and form. A dozen young transplanted cordons on the Paradise stock were, last season, clustered with fruit; judiciously thinned, they produce handsome fruits rather larger than Cox's Orange Pippin. It appears to be the rule with this variety that the smaller the fruit the better the flavour, and I am of opinion that as trees, with age, produce smaller fruits, the flavour will improve; some growers are inclined to over-feed their young trees of this variety. As stated by *One of the Judges*, "Charles Ross" obtained the first prize in the "any other variety" class for dessert Apples at the R.H.S. Fruit Shows of 1906 and 1907, and I understand that in this class the decision is determined by flavour. *A Devonshire Grower.*

——— I have seen the original tree of the above Apple for the past three seasons, and it has produced each year a good crop of fruits for the dessert table. As I write it is studded with flowers, each bunch having been thinned to one flower, and after setting will be thinned again, whilst Peasgood's Nonsuch never bears a crop with my neighbour, Mr. C. Ross. I think I am correct in saying that the Apple Charles Ross is unique as being the only Apple to obtain an Award of Merit and a First-Class Certificate from the R.H.S. in the same year. I consider this variety to be the best that Mr. Ross has raised, and he has distributed a round dozen. The above-mentioned Apple was raised from one of four seeds out of the same fruit, which also yielded the Houblon and Rival. At the fruit show last autumn, C. Ross Apple was shown in the class for "any other variety." Mr. Chas. Ross and one of his sons (a schoolmaster at Winchester) were in opposition, and the son beat the father with his own Apple, taking the 1st prize. I should advise *A Working Grower* not to despair, but give it a further trial in a different position. *E. Y., Newbury.*

CANADIAN WOOD PULP.—A new company has been organised in Vancouver to utilise the enormous waste material from the saw and shingle mills of the country. Most of this refuse is at present burned to prevent accumulation, but as raw material for paper-making it has a considerable value. The abundant water power will enable the machinery to be run cheaply, and it is stated that a process has been discovered which will render it possible to make use of the Douglas Fir and other resinous wood for paper-making. The wood, when brought to the works, is reduced to small shavings or chips, and is then digested with a hot solution of caustic soda for several hours—after being washed and bleached and further pulverised it is fit for the final paper-making machines. The industry ought to be a paying one, having regard to the amount of lumber waste that is ready for use. No doubt care will have to be taken that the local forests are not injured by cutting the young trees, in order to supply additional material for the mill, seeing that stuff which is too small for ordinary lumbering can readily be converted into paper.

SOCIETIES.

ROYAL HORTICULTURAL.

JUNE 9.—Although there was a beautiful display of floral subjects at the meeting held on this date, there was a small attendance of the Fellows, due, of course, to the show being on a day immediately following a Bank Holiday, and before many of the members had returned to town. This is unfortunate, as the gathering and preparing of such a show involves much work on the part of exhibitors the day preceding, when other folks are keeping holiday. The show was very largely comprised of hardy garden plants, amongst which Irises, Pyrethrums, and Pæonies predominated. There were also many fine displays of Orchids, greenhouse plants, including Carnations in number, and a few exhibits of fruit. Both the FLORAL and the ORCHID COMMITTEES had many novelties brought before their notice, and of these several were selected for awards. In the afternoon a lecture was delivered by Sir George Birdwood, K.C.I.E., C.S.I., on "Wild Flowers and Wild Sh[illegible]."

Floral Committee.

Present: W. Marshall, Esq. (in the Chair), and Messrs. H. B. May, W. Bilney, Chas. T. Druery, E. Bowles, T. W. Turner, Geo. Reuthe, C. R. Fielder, W. Howe, John Jennings, C. J. Salter, W. Bain, Geo. Gordon, Chas. Dixon, J. T. Bennett Poe, Chas. E. Shea, W. P. Thomson, E. H. Jenkins, H. J. Cutbush, Edw. Mawley, E. T. Cook, and James Hudson.

Messrs. JAS. VEITCH & SONS, LTD., King's Road, Chelsea, showed eight tall pyramidal-trained Fuchsias, Gloxinias in variety, some grand pans of Cypripedium spectabile, Primula Cockburniana, a blue-flowered Meconopsis from the Himalayas, a collection of annuals in flower, Eremurus, Aquilegias in variety, Anchusa italica, and many other hardy garden plants. (Gold Medal.)

Messrs. W. CUTBUSH & SON, Highgate, London, N., displayed a beautiful exhibit of Carnations all of high quality and staged with skill; many pretty flowered Rhododendrons; the new variegated variety of Ivy raised by Mr. Russell, and many other interesting plants. (Silver-Gilt Flora Medal.)

Messrs. H. B. MAY & SONS, The Nurseries, Edmonton, arranged a collection of Verbenas, in various colours, and all of named varieties. There were also Heliotropes, Swainsonia galegifolia, white variety, a large-flowered Abutilon named Triumphans, with many beautiful Ferns interspersed. (Silver Flora Medal.)

Messrs. HUGH LOW & Co., Bush Hill Park, Enfield, again showed Meterosideros floribunda, also Carnations, Roses, Hydrangeas, Pelargoniums, &c. (Silver Flora Medal.)

Messrs. H. CANNELL & SONS, Swanley, Kent, arranged a semi-circular group of Cannas in most of the improved varieties. (Silver Flora Medal.)

Mr. C. F. WATERS, Deanland Nurseries, Balcombe, showed Carnations in variety. (Silver Banksian Medal.)

A batch of well-cultivated plants of Schizanthus wisetonensis and another of Rehmannia angulata were put up by Mr. H. Prime, gardener to the Marquis of SALISBURY, Hatfield House, Herts.

J. A. YOUNG, Esq., West Hill, Putney (gr. Mr. G. H. Street), showed some large plants of Gloxinias well-flowered, and a number of herbaceous Calceolarias.

Messrs. DOBBIE & Co., Rothesay, showed Violas and Pansies in variety; whilst another display was made with these flowers by Mr. H. F. PATMORE, Lymington.

Mr. H. BURNETT, Guernsey, showed Carnations in variety, all finely cultivated and attractively displayed. (Silver Banksian Medal.)

Messrs. CARTER, PAGE & Co., 52 and 53, London Wall, London, showed Dahlias, Fuchsias, Antirrhinums, Viscarias, Phloxes, &c.

Messrs. ROBT. VEITCH & SONS, Exeter, displayed their hybrid Calceolaria that was figured in the *Gardeners' Chronicle*, June 29, 1907, p. 426; a magenta-coloured Stock, with very large inflorescences; a form of Rehmannia angulata, with deep pink-coloured flowers, the blue Lathyrus pubescens, Ononis fruticosa, &c.

Adjoining Messrs. VEITCH'S Calceolarias were other plants of the same variety displayed by

LEOPOLD DE ROTHSCHILD, Esq., Gunnersbury House, Acton (gr. Mr. Hudson).

Mr. ROBT. NEAL, Trinity Road, Wandsworth, had several vases of Sweet Peas.

Messrs. W. BULL & SONS, King's Road, Chelsea, staged a number of stove and greenhouse plants of an ornamental-leaved type.

Messrs. GILBERT & SON, Dyke, Bourne, Lincolnshire, had some pretty Anemones, Aquilegias, &c.

Messrs. PAUL & SON, Cheshunt, had sprays of many interesting trees and shrubs in flower, also an assortment of Roses. (Silver-Gilt Banksian Medal.)

Messrs. KELWAY & SONS, Langport, Somerset, exhibited a very large group of Pæonies, including many of the choicer varieties for which the firm is noted; also Pyrethrums, Delphiniums, &c. (Silver-Gilt Banksian Medal.)

Messrs. BAKERS, Codsall, Wolverhampton, exhibited a choice strain of Aquilegias, also Oriental Poppies, Pyrethrums, and other showy garden flowers. (Silver Banksian Medal.)

A meritorious exhibit of hardy flowers was from Messrs. R. H. BATH & Co.'s Wisbech Nurseries. The usual seasonable subjects were included, such as varieties of Pyrethrum, Delphiniums, Poppies, Irises, &c. (Silver Flora Medal.)

Messrs. GEO. BUNYARD filled a long table with border flowers in fine assortment, a goodly portion of the table being occupied with Irises in variety. (Silver-Gilt Banksian Medal.)

Messrs. JOSEPH CHEAL & SONS, Crawley, Sussex, had an interesting lot of Lupins, both tree and border varieties; the flowers were of white, yellow, blue and pink colours. (Bronze Flora Medal.)

Mr. MAURICE PRICHARD, Christchurch, Hants, had an extensive array of seasonable garden flowers, all presented in an attractive manner and including many rarities. (Silver-Gilt Banksian Medal.)

Exhibits of hardy flowers were also shown by Mr. G. REUTHE, Keston, Kent (Silver Flora Medal); Messrs. G. & A. CLARK, LTD., Dover (Silver Flora Medal); Mr. AMOS PERRY, Enfield, Middlesex (Silver Flora Medal); Misses HOPKINS, Mere Gardens, Shepperton-on-Thames; Messrs. GEO. JACKMAN & SONS, Woking (Silver Banksian Medal); GUILDFORD HARDY PLANT NURSERY; JOHN PEED & SONS, West Norwood. (Silver Flora Medal); KING'S ACRE NURSERY Co., Hereford (Silver Banksian Medal); and Messrs. R. & C. NOTCUTT, Woodbridge.

AWARDS OF MERIT.

Pyrethrum "*Langport Crimson.*"—A handsome, single-flowered variety of a shade of rich velvet-crimson. The plant appears to possess a vigorous habit of growth. Shown by Messrs. JAMES KELWAY & SON, Langport.

Iris × *Carthusiana.*—This variety is said to have resulted from the intercrossing of an unnamed species collected near Mardin, in Syria, and I. pallida Dalmatica, the latter being the pollen parent. The hybrid has a similar fragrance to varieties of I. pallida, but the whole flower is of more uniform build, and the leafage has not the broad, glaucous, erect character typical of the pallida section. Save for the white and gold reticulations near the base of the falls, the large and handsome blossoms are coloured a lavender-blue shade. Exhibited by J. W. MARSHALL, Esq., Charterhouse, Godalming.

Zephyranthes aurea.—This Peruvian species has a rich, golden-coloured perianth, nearly 3 inches across the widest part: the tube is glaucous, and especially so near to its base. The leaves are rather more than 1 foot in length, narrow-channelled, and distinctly glaucous beneath for about half their length, less so as the acutely-pointed tip is reached. The plant flowered during the early autumn of last year, the scape then appearing in advance of the leaves, but the inflorescence has now developed contemporaneously with the foliage. The plant was exhibited by Sir TREVOR LAWRENCE, who received it from his son in South Africa, whither it had been introduced from Peru.

Philadelphus Lemoinei rosace. — Flowering sprays of this shrub were also exhibited by Sir TREVOR LAWRENCE. The solitary flowers are white, semi-double, and not unlike a Rose, save from the diminished size of the inner petals.

Rhodothamnus Kamtschaticus.—A dwarf-growing shrub, whose leaves approximate somewhat to those of a miniature Rhododendron sinense. The hooded or cupped blossoms are a shade of purple, and are produced in small clusters, supported by inch-long pedicels. The species is a fit subject for planting in the rock-garden. Shown by Mr. GEO. REUTHE, Keston, Kent.

Carnation Snowball—This white variety possesses excellence of form and fulness of petals, and is representative of an excellent type of Carnation, equal to a good border variety, although belonging to the "tree" section. The petals are not pure white, but just suffused with a blush tone. Exhibited by Mr. H. BURNETT, Guernsey.

Stock, Veitch's Magenta strain.—An Award of Merit was granted for a strain of Brompton Stock shown under the above name by Messrs. ROBERT VEITCH & SON, Exeter.

Rosa Moyesii.—A new species from China, with vigorous habit of a pronounced briar-like character. The stems are abundantly furnished with strong spines. The leaves are long, firm in texture, 10-11-lobed. The blossoms are 2 inches or more across, and in the expanded flowers of a pleasing ruby-red tone, but in the bud state they are cardinal red; the petals are leather-like in texture. The species should prove of value to the hybridist.

Deutzia Wilsonii.—A Chinese species, with firm, slightly-notched, lance-shaped, oppositely-placed leaves. The terminal and axillary clusters of large, pure-white flowers are very freely-produced, the shoots being closely set with flower-buds for almost their whole length. These two last-named were presented by Messrs. JAS. VEITCH & SONS, LTD., Chelsea.

Orchid Committee.

Present: Harry J. Veitch, Esq. (in the Chair), and Messrs. Jas. O'Brien (hon. sec.), Sir Jeremiah Colman, Bt., H. Little, W. Boxall, Stuart Low, F. Sander, H. G. Alexander, J. Cypher, C. H. Curtis, A. A. McBean, R. G. Thwaites, A. Dye, J. Charlesworth, H. A. Tracy, Gurney Wilson, F. J. Hanbury, and R. Broomman-White.

Messrs. CHARLESWORTH & Co., Heaton, Bradford, were awarded a Silver Flora Medal for a select group of exceptionally finely-flowered plants among which were Renanthera Imschootiana with over 40 leaves and a strong spike of bright-reddish, scarlet flowers; fine Lælio-Cattleya Canhamiana and L.-C. Canhamiana alba, with five flowers; L.-C. Fascinator, an intensely dark L.-C. Dominiana; L.-C. G. S. Ball, with 13 apricot-yellow blooms; and a selection of hybrid Odontoglossums.

Messrs. SANDER & SONS, St. Albans, were awarded a Silver Flora Medal for an interesting group, in which, among a good selection of varieties of Cattleya Mossiæ and C. Mendelii, were a large specimen of Lælio-Cattleya exoniensis with many flowers, Odontoglossum ardentissimum, O. Hallio-crispum, and other hybrid Odontoglossums; good Lælia purpurata, Phaius Cooksoniæ, &c. Among species were noted the true Oncidium ampliatum majus with showy, yellow flowers, Lycaste lanipes with many cream-white blooms, the reddish-scarlet Renanthera Imschootiana, and Bulbophyllum orthoglossum, a fine Malayan species of the B. mandibulare section, with yellow flowers striped and marked with red-brown. Messrs. SANDER also showed the new Sobralia Siebertiana (macrantha alba × Hodgkinsoniii), a large mauve-purple flower with white tube to the lip, which is very broadly developed.

Messrs. HUGH LOW & Co., Enfield, were awarded a Silver Flora Medal for a large and well-arranged group, in which the forms of Cattleya Mossiæ were very fine, and included two C. M. Reineckiana. Good forms of C. Mendelii, C. intermedia alba, Lælia purpurata, the richly-coloured Cypripedium Gowerianum, Schofield's variety, C. Wm. Lloyd magnificum; and a good selection of Odontoglossums, Lælio-Cattleyas were also included.

Messrs. J. & A. A. McBEAN, Cooksbridge, secured a Silver Banksian Medal for a pretty group, all the specimens staged being excellently well grown. Cattleya Mossiæ Aureola was a very distinct variety, with white sepals and petals slightly tinged with lilac, and having silver-white midribs, the lip being white with pale-orange disc. C. Mossiæ Jaffa had deep, rose-coloured sepals and petals and orange-coloured lip, on which were white veinings, the crimped margin being tinged with rose. A good form of C. M. Reineckiana; a distinct form of Lælio-Cattleya Martinetti; some very fine Odontoglossum crispum, including O. c. Xanthotes; a grand specimen of O. luteo-purpureum, with a spike of 14 large blooms; and the new O. gloriosum citrinum.

De B. CRAWSHAY, Esq., Rosefield, Sevenoaks (gr. Mr. Stables), showed an interesting and pretty group of hybrid Odontoglossums, for which a Silver Banksian Medal was given, and which included several of his superb strain of O. Queen Alexandra (Harryanum × triumphans), the best, the variety Crawshayanum, which secured a First-Class Certificate, being superior to the variety Carmen, for which Mr. CRAWSHAY received an Award of Merit, June, 1906. Two varieties of O. crispodinei (crispum × Coradinei) showed it in much better form than when first exhibited, one plant having three spikes of cream-white flowers, with a large, reddish blotch in the middle of each segment. O. Urania (crispum × cristatellum), O. Lambeauianum of very pretty type, O. Persephone (Pescatorei × Adrianæ), and other Rosefield hybrids were also shown.

Messrs. STANLEY & Co., Southgate, were voted a Silver Banksian Medal for a very fine display of Cattleya Mossiæ, some 80 specimens being used in the group. The coloured varieties were very bright, and the best of the light forms was C. Mossiæ Thompsonii, with white sepals and petals slightly tinged with rose, the large disc of the lip being yellow, with slight rose markings on each side.

Mr. A. W. JENSEN, Lindfield, Sussex, was awarded a Silver Banksian Medal for a group of Cattleyas and Odontoglossum crispum, all of excellent quality.

Messrs. JAS. VEITCH & SONS, Chelsea, staged a group of remarkably fine Cypripedium spectabile. The specimens were dwarf and compact, and probably among the best yet shown.

Monsieur MERTENS, Mont St. Amand, Ghent, showed a selection of hybrid Odontoglossums.

G. W. BIRD, Esq., Manor House, West Wickham (gr. Mr. Redden), sent as Odontioda Wickhamensis a hybrid said to be between Odontoglossum crispum and Cochlioda rosea, but which some members of the Committee pronounced to be Odontioda Heatonensis (O. cirrhosum × C. sanguinea).

WALTER COBB, Esq., Normanhurst, Rusper (gr. Mr. C. J. Salter), sent a fine plant of Lælio-Cattleya Martinettii Dulcotensis, with two spikes of seven flowers having bronzy, salmon-coloured sepals and petals, and near to Messrs. Sanders' fine variety Flambeau.

AWARDS.

FIRST-CLASS CERTIFICATE.

Miltonia St. André (M. Roezlii × *M. Bleuana, Sanders' variety)*, from Baron Sir H. SCHRÖDER, The Dell, Egham (gr. Mr. Ballantine). The delicately-tinted flower is rounder than M. Bleuana, and the fine violet-purple tint on the inner halves of the petals strongly indicates M. Roezlii. The sepals and outer halves of the petals are white. Lip broad, white, with a brownish-red mask of radiating lines at the base, the three central lines being tinged with ruby-red; a few very thin, dark lines form a tracery on each side of the column.

Odontoglossum Phœbe (cirrhosum × *crispum)*, from Baron Sir H. SCHRÖDER, The Dell, Egham (gr. Mr. Ballantine).—A grand form of this pretty hybrid, with flowers equal to some of the varieties of O. ardentissimum, and very brightly coloured. Ground colour white, uniformly blotched with deep, purplish-red, a band of purple extending up the petals from the base; crest yellow.

Odontoglossum "*Queen Alexandra,*" *var. Crawshayanum (triumphans* × *Harryanum)*, from DE B. CRAWSHAY, Esq., Rosefield, Sevenoaks. A grand flower resembling the phenomenal O. triumphans Lionel Crawshay in shape, size, and substance. Sepals and petals yellow, the ground colour almost obscured by large, deep, purple-brown blotches. Front of lip white, the basal three-fourths prettily marked with rose-purple.

AWARD OF MERIT.

Odontoglossum gloriosum citrinum, from Messrs. J. & A. A. McBEAN, Cooksbridge. A very pretty variety, which comes under the albino class, the brown spotting usually seen in the species being suppressed, and the flowers entirely of a pale citron yellow, with a slightly darker tint where the spotting would be if developed. It is a pretty and fragrant novelty.

Miltonia Bleuana Stevensii (Roezlii alba × vexillaria Leopoldii), from WILLIAM THOMPSON, Esq., Walton Grange, Stone, Staffordshire (gr. Mr. Stevens).—A very pretty, dwarf and floriferous variety, with white flowers, having thin, red-brown lines at the base of the lip. Six plants, each well bloomed, were shown.

CULTURAL COMMENDATION.

To Mr. May (gr. to J. B. JOEL, Esq., Childwickbury, St. Albans, for a fine specimen of Cypripedium Rothschildianum, Northaw variety, with fine spikes, one of which bore six flowers and one bud.

Fruit and Vegetable Committee.

Present: Geo. Bunyard, Esq. (in the Chair), and Messrs. Alex. Dean, Jos. Cheal, John Basham, Chas. D. Walter, A. R. Allan, Thos. Coomber, James Vert, Joseph Davis, Geo. Reynold, J. Jaques, Chas. Foster, Geo. Wythes, A. H. Pearson, and John Harrison.

Mr. S. MORTIMER, Rowledge, Farnham, Surrey, displayed two varieties of Cucumbers, named respectively Faultless and Evergreen. They are the result of crossing Market Rival with Improved Telegraph, the cross being effected both ways. Faultless is the larger fruit, Evergreen being the darker in colour. (Silver Banksian Medal.)

Messrs. JAMES VEITCH & SONS, Ltd., King's Road, Chelsea, exhibited a number of pot plants of Peaches and Figs, all well fruited and having healthy, vigorous foliage. The Figs included Violette Sepor, St. John's, White Ischia, and Early Violet; and the Peaches Duchess of Connaught and Duke of York. (Silver-Gilt Knightian Medal.)

A box of very large fruits of Nectarine Early Rivers, shown by S. HEILBUT, Esq., The Lodge, Holyport, Maidenhead, was granted a Cultural Commendation.

A Silver Banksian Medal was awarded to an exhibit of preserved fruits shown by Miss C. E. MARTIN, Willowbrook, Auburn, New York, U.S.A.

VISIT OF THE R.H.S. COMMITTEES TO WINDSOR.

JUNE 11.—Glorious weather favoured the visit of the Council and Committees of the Royal Horticultural Society to Windsor Castle and Frogmore gardens on Wednesday last. About 100 members availed themselves of the King's gracious permission. At one o'clock the party was entertained as guests of the Mayor of Windsor at luncheon in the Windsor Town Hall. His Worship was supported by Sir Trevor Lawrence, Bart., Major Holford, C.I.E., C.V.O., Sir J. T. D. Llewellyn, Bart., Sir Albert Rollit, J. Gurney Fowler, Esq., the Rev. W. Wilkes, M.A., Mr. A. Mackellar, head gardener at Frogmore, and nearly all the members of the Council, as well as some of the Society's officials. The speeches at the luncheon were very brief. The Mayor proposed the health of the King, the Queen, and the Royal Family. Sir Trevor Lawrence then voiced the thanks of the guests to the Mayor, and proposed his health, this toast being received with musical honours.

It had been proposed that at the close of the luncheon the party should proceed in brakes direct to the gardens. That programme had, however, to be altered in consequence of a visit from the Maharajah of Nepaul and his suite to the Royal Gardens. As a result, the Horticultural party was invited to first visit St. George's Chapel; then the State apartments in the Castle, and later passing from those over the beautiful East Terrace, through the Home Park to the Frogmore Mausoleum—a weary walk, but through glorious surroundings. Thence over the lawn to Frogmore Cottage, where there are some noble trees, to the gardens. In these, the party, breaking up into several groups, was conducted by Mr. Mackellar and Mr. E. Harris, and in every house, no matter what its contents, Orchids, Carnations, Palms, Hydrangeas, Grapes, Peaches, Nectarines, Melons, Cucumbers, or Tomatos, everything was so excellent as to evoke on every hand the highest praise. The wall and other fruit trees, the huge expanses of vegetables, the wonderful long and gay hardy plant borders, the bothies, everything was in the most perfect condition, and Roses by thousands were blooming gloriously on every side. If Mr. Mackellar had a critical party of visitors, at least their criticisms were all of an admiring kind. It was a visit which all who shared in it will remember for a long time to come.

SCOTTISH HORTICULTURAL.

JUNE 2.—The monthly meeting of this association was held at 5, St. Andrew Square, Edinburgh, on this date, Mr. Whytock, the president, occupying the chair. There was a good attendance of members. Mr. James Harris, Inverleith Park, Edinburgh, read a paper, illustrated with lantern slides, on "Some Principles Governing Practice in Horticulture." Mr. Harris explained the physiology of such ordinary gardening operations as budding, grafting, cutting, striking, pruning, &c. It was intimated that the paper for the meeting on July 7 would be one on the Strawberry by Mr. D. Kidd, Carberry Tower, Musselburgh, and that a Strawberry conference will be held on July 14. It was also announced that the annual excursion will be to Drummond Castle, Crieff, on July 18. The money collected on behalf of the Royal Gardeners' Orphan Fund at the monthly meetings from January to May has amounted to £2. Thirteen new members were elected.

ROYAL SCOTTISH ARBORICULTURAL.

(ABERDEEN BRANCH.)

MAY 23.—Mr. William Dawson, the lecturer in forestry to the Aberdeen and North of Scotland Agricultural College, gave a lecture within the Botany Class-room, Aberdeen University, on the above date to the members of this branch on the subject of "Forestry in Germany."

Mr. Dawson said that in Germany there were a little over 34½ million acres of forest, equalling 26 per cent. of the total land surface. Of this, about one-third belonged to the Crown, one-fifth to various institutions, and the remaining half was private property. It was difficult for the people in this country, with its 4 per cent. of forest, to fully realise what it meant to have a quarter of the land surface under timber. Germany was not by any means the most densely wooded country in Europe, but only stood about the middle as regarded land surface under timber. Russia had 38.5 per cent. of its land surface in timber, or 5 acres per head of the population; Switzerland had 20.5 per cent., or 6.5 acres per head; France had 18 per cent., or 0.6 acre per head; while Britain had only 3.9 per cent., or .075 acre per head. Britain was thus an easy last with its 363 square yards of forest per head of the population. Although the area under forest in Germany was great, it was being increased by 2½ million acres of moorland, which has been considered fit for growing timber. This land is being gradually afforested by the State. As in this country, about one half of the forests was owned by private individuals, but there was little fear of these private owners lessening the area under wood. In most of the German States reafforestation was compulsory, the time limit being three years, with a penalty where this law was infringed. The German Government provided a staff of officials to assist private forest owners. These officers were on the same level as other Government forest officers, and their sole duty was to help private owners where assistance was needed. The system of afforestation pursued was interesting in the extreme. The ground was ploughed and cultivated in the ordinary way—when on a large scale the steam plough was brought into requisition. Then a Rye crop or Oat crop (in most cases Rye) was sown, and along with the corn the tree seeds were sown broadcast. In autumn the cereal crop was cut, a high stubble being left, and was harvested in the ordinary way. In the shelter of the long stubble the seedlings came away well, and generally a full crop was secured. The advantages of such a system were obvious—the cost of laying down was nil.

The State supplied plants at cost price where necessary, the plants being reared in the ordinary nurseries attached to the Government forests. As showing the activity of recent years in this department of German economics, it was found that in Bavaria, in 1885, 15 million plants were distributed, whereas in 1905 the annual output had reached 50 millions. The species of trees grown in Germany were practically the same as in this country. In 1900, 67.5 per cent. of the land bore coniferous wood, and the remaining 32.5 per cent. were hardwood trees. A remarkable feature was the position of the Larch, which only occupied .1 per cent. of the total forest area, i.e., 34,000 acres, while Spruce occupied nearly 7,000,000 acres, and Scotch Pine 15,500,000 acres. The outstanding general principle of management was that the annual felling did not exceed the annual production, and, consequently, a regular annual income was got, and not a spasmodic one, as in Great Britain.

Coming now to the profits that are derived by Germany from her forest area, the results are truly astonishing. In Saxony, the profits of late years have been upwards of 20s. per acre, after accounting for all expenses—cost of laying down, compound interest, value of the land, cost of management, &c.—during the life of the wood. The interest on the money expended is calculated at from 2½ to 3 per cent. In the period 1895-9 it was calculated that the net average profit from the State woods all over Germany was about 9s. per acre. Then there was a clear annual profit of £4,500,000 added to the national coffers from this source. And then consider the employment it offered. Roughly speaking, every 120 acres gave employment to a man. The economic effect on the German nation was enormous. There, afforestation is looked upon less as a lucrative investment for capital than as an industry of the utmost importance for the well-being of the country.

Another feature to be noted in the German system was the grand system of forest roads. Every part was accessible, and a regular network of lanes and paths run over the whole woods. Love of the woods was deeply ingrained in the German people, and it was to the woods the German holiday-maker invariably went. These State woods are all open to the public, who can wander about them at their own will.

But one of the most interesting features of afforestation in Germany was the vast number of people for whom it finds employment. There was a total of 230,000 men on the State insurance list as State wood workers, and the year's wages bill for felling, planting, &c., approached £9,000,000. Between sawmills and factories using wood another £25,000,000 was spent in wages. The importance of the making of wood-pulp as an industry was also seen from the fact that since 1851, when the first wood-pulp mill was started in Saxony, the number had increased to 633 in 1903, using altogether about 35,000,000 cubic feet of wood.

Mr. Dawson's paper, which went to prove that the afforestation of this country ought to be under State control, was listened to with much interest, and an animated discussion followed, taken part in by Mr. Crozier, forester, Durris; Mr. C. S. France, Aberdeen; Mr. James Hendrick, Agricultural College; Mr. Braid, factor, Durris; Mr. Rule, Huntly; and Dr. James W. H. Trail, Professor of Botany in Aberdeen University.

COMMONS AND FOOTPATHS PRESERVATION.

JUNE 6.—Lord Eversley, who presided over the monthly meeting of this Society on the foregoing date, reported that a deputation from the Society had waited upon the Board of Agriculture to urge that consent should not be given to several applications under the Allotment and Small Holdings Act for power to enclose common land, and that the agreement between the War Office and the verderers of the New Forest to secure proper regard to public interests in connection with the holding of military manœuvres in the forest during August and September had now been approved by the Society's solicitors and signed. It was decided to hold the annual meeting of the Society in the theatre of the Royal United Service Institution, Whitehall, on Wednesday, June 17, at 3 p.m., when it is expected that Lord Eversley, Lord Farrer, Sir John Brunner, M.P., Mr. J. Ramsay Macdonald, M.P., Sir Robert Hunter, Mr. E. N. Buxton, Mr. C. Trevelyan, M.P., Mr. St. Loe Strachey, and other members of the Society will take part in the proceedings.

ANSWERS TO CORRESPONDENTS.

ABNORMAL ASPARAGUS: *G. T. H.* Your very large shoot of Asparagus affords an example of fasciation which is due to fusion of growth. The five shoots, totalling 1¾ lb., constitute a greater weight than any we have recorded in our "Record" Book. The entry having the largest weight in our book is on June 7, 1831, when 112 heads, grown by Mr. Grayson, Mortlake, are said to have weighed 30 lbs. This works out at about 4 2-7 ozs. per shoot, whereas yours are considerably more than 5 ozs. each. The plant could, of course, be propagated from seed, but it is questionable if the character of fasciation is a desirable one to perpetuate. Some of the seedlings might show a disposition to develop this abnormality, and it may be some would produce shoots of a larger size than the parent. The surest way, however, would be by division of the old crown, but the work of separation needs to be carefully performed.

ABNORMAL FOXGLOVE: *S. C.* The flower-spike you send shows an example of Peloria, a condition in which the top flower has become regular. This is common to the plants of the Foxglove family, and it is often seen in Antirrhinums. The supposition that your flower has been crossed with a Hollyhock is erroneous, for the plants belong to entirely different families.

ASTERS DYING: *G. W. R.* Our expert states that the injury is not caused by a fungus, but is the result of some unsuitable cultural treatment.

BEECH HEDGE INFESTED WITH FLIES: *H. J. Webb.* The small black fly is a species of Bibio, allied to the so-called St. Mark's fly (B. marci), if not specifically identical with it; but the specimens were so much damaged by moisture that the specific characters were destroyed. However, the flies are harmless, and will, in all probability, disappear in a few days. They are not known to be injurious to vegetation, as the larvæ feed chiefly on decayed vegetable matter. The Beech aphis is in no way related to them.

BEGONIA RUST: *Anxious.* The plants are badly infested with the mite that causes the leaves, especially on the under-surface, to present a brown appearance. Dip the foliage in tobacco water, and be careful to burn any fallen leaves and all of them in the autumn when they are shed.

BOOKS: *J. T.* There is no book on Sempervivum and no recent monograph of the genus. Nobody appears to have attempted a classification of the species since Mr. J. G. Baker did so in the *Gardeners' Chronicle*, 1874, ii., p. 103. You will find nothing better on the garden species of Sempervivums than that given in *Nicholson's Dictionary of Gardening*. Jordan and Fourreau's *Icones ad Floram Europæ*, vol. i., includes descriptions and coloured plates of numerous species, but this work is very costly, and would supply only a partial knowledge of the genus. In course of time the whole of the Crassulaceæ will be monographed in Engler's *Pflanzenreich*, but the part containing this Order has not yet appeared.

CARNATION DISEASE: *Carnation Rust.* The foliage with the black marking is attacked by a fungus, Helminthosporium, and the other is apparently suffering from eelworm. If the disease and eelworm are present in considerable quantities, it will be best to commence afresh with new stock, being careful to first burn the old plants, thoroughly sterilise the soil, and cleanse the structure in which the Carnations will be cultivated.

CATERPILLARS ON EUONYMUS. The best plan for ridding plants of this pest is to spray them with an arsenical poison, such as Paris green or London purple, the former for preference.

CHIONODOXA ROOTS: *Nedos, Chard.* The large fleshy roots are examples of contractile roots. They are common to many bulbous plants, and serve, later on in the season, to pull the bulb down into the soil.

CONIFERS AND CATTLE: *J. E. D.* Most of the Conifers, including the common Scots Fir, are not harmful to cattle, but should there be any Yew trees in the park you must keep the cattle from them, as dangerous results follow when cows, &c., browse upon their shoots.

EGGS IN SOIL: *W. H. G.* The eggs when received were dried up. They are either worms' or snails' eggs.

FRUITERER AND FLORIST: *G. W.* We cannot undertake to recommend a firm; you had better advertise.

GARDENER'S NOTICE: *J. S.* In the issue of February 29 last, p. 144, a reply was given to a correspondent on this subject. If you are paid weekly you would probably be held entitled to a week's notice. It has been decided that a head gardener, paid at a yearly rate, is entitled to a month's notice. In your own case, as a foreman gardener paid weekly, you can only claim a week's notice.

GOOSEBERRIES DISEASED: *H. C.* The disease attacking your Gooseberry leaves is nothing serious. It is caused by Gloeosporium ribis. If the diseased leaves are collected and burned a recurrence of the injury will be prevented.

GREENHOUSE PLANTS: *S. S.* We suppose that by the term greenhouse plant is meant a species that is generally cultivated in a cool house as distinguished from the stove. But in using the term in an Exhibition schedule there is liable to be some misunderstanding, because whilst some cultivators have a particular species in the stove others prefer to keep it in the greenhouse. Instances are afforded by the two plants you mention. Bougainvillea glabra is frequently to be seen in the hottest stoves, but it will succeed in moderately cool houses and corridors; for instance, the large plant in the exhibition hall in the Edgbaston Botanical Gardens, and in very mild situations, such as the Under-cliff at Ventnor, and sheltered spots in Cornwall and Devonshire, the Bougainvillea will thrive out of doors until killed by a frost of unusual severity. Coleus is generally regarded as a stove plant, but it will thrive very well during the summer period in the greenhouse or conservatory. In such a matter, and assuming that a list of plants is not printed in the schedule, the judges are left to exercise their discretion, and in the circumstances you will do well to exhibit species that are not likely to afford grounds for dispute. Such species might include the tuberous Begonia, Celosia, Pelargonium, Fuchsia, Schizanthus, Cestrum, Plumbago, Crassula, Cineraria, Camellia, Rhododendron indicum, and cool-growing Palms, Ferns, and other ornamental foliage plants, selecting those in season at the time the exhibition is held.

HAIL STORM INSURANCE COMPANY: *E. B H.* The address of the secretary, Mr. A. J. Munro, is 4, King Street, Covent Garden, London, W C.

INSECTS: *G. & S.* Your plants are attacked by one of the millipedes, "the spotted snake millipede" (Blanjulus guttulatus), a very destructive pest, and one which appears to have attacked your plants in unusual numbers. They may be killed at once by very hot water; but the usual insecticides have little or no effect on them. The only practical way to rid your soil of them is to remove all vegetable matter on which they can feed, and give the ground a good dressing of gas lime or "Vaporite," letting it remain fallow for some months after the application of gas lime.

INSECT ON ROSE: *J. S.* and *F. D. & Co.* The insect is the common clay-coloured weevil. See reply to *T. C.* in our issue for May 23, p. 340.

MAGNOLIA GRANDIFLORA: *W. F.* This plant does not require much pruning, but only to have the least promising growths thinned out that the better ones may be trained on the wall. The proper time to do this thinning is directly after the plant has flowered in spring. If the specimen has already made much growth, you had better defer the operation until next spring.

MARROWS: *G. M.* It is possible the roots would be able to utilise a small quantity of sugar, but quite insufficient to repay you for applying sugar as a manure.

NAMES OF PLANTS: *F. L.* 1, Lastrea Filix-mas var. cristata; 2, Vancouveria hexandra; 3, Epimedium musschianum; 4, Too crushed to recognise *H. W.* 1, Pernettya mucronata; 2, Gaultheria Shallon; 3, Rubus nutkanus; 4, Polygonum cuspidatum; 5, Leucothoë Catesbæi; 6, Anchusa italica.—*Vius.* 1, Tellima grandiflora; 2, Centaurea montana var.; 3, not recognised; 4, Saxifraga hypnoides; 5, Kerria japonica, variegated variety; 6, Skimmia japonica.—*Correspondent.* 1, Coloured form of Chenopodium Bonus-Henricus; 2, Epimedium alpinum.—*C. W.* 1, Gerbera Jamesonii; 2, Fair Maids of France (Ranunculus aconitifolium); 3, Anchusa sempervirens.—*G H.* Veronica spicata.—*Miss E.* 1, Cornus Kousa; 2, Brodiæa congesta.—*T. S.* 1, Stachys sylvatica; 2, Nepeta Glechoma; 3, Marrubium vulgare; 4, Lamium album.—*A. M.* 1, Luzula campestris; 2, next week.

PEARS DISEASED: *J. B.* The fruits are infested with the Pear midge maggot. At this stage you can do nothing better than pick off all the diseased Pears and burn them. Kainit sprinkled on the ground under the trees at the rate of 5 cwt. per acre destroys the larvæ as they drop from the fruits to hybernate in the ground.

ROSE ROOT: *C. H. P.* The root-stock you forwarded appears to be perfectly healthy, with the exception of one large centre root, which is dead. The roots are in as good a condition as can be expected from an old root-stock There is no fungus present.

TOMATOS DISEASED: *H. A.* The foliage is attacked by a fungus—Macrosporium solani. Spray the leaves with the Bordeaux mixture and ventilate the house freely, maintaining a dry atmosphere. — *J. H.* The plants are affected with "Sleepy disease." Water the roots thoroughly with a solution of sulphate of potash. The infected soil should be sterilised with lime before being used again.—*G. W. R.* Your Tomatos exhibit the disease caused by Macrosporium solani. Destroy all the infected fruits by burning.

TWIN TULIPS: *G. C. P.* These are not uncommon: we receive many branched Tulips at this office during the season.

VINE LEAVES SCORCHED: *W. S. H.* No disease is present in the leaves you send; the injury has been caused by scalding. We do not think the drain pipes have any connection with the injury. Be careful to ventilate freely, and avoid wetting the leaves during very bright sunshine.

WEED IN LAWN: *W. E.* The plant is a species of Trifolium, probably T. minus. Its presence in quantity indicates an excess of potash in the soil and a deficiency of nitrogen. Give the grass a dressing of sulphate of ammonia, after which the growth of the grasses will soon crowd out the Clovers.

WILLOW CULTURE: *Information.* A lengthy article on this subject appeared in the *Gardeners' Chronicle* of October 23, 1880, p. 538. Much information on the subject may also be found in *Practical Forestry* and *Forester's Diary*, both of which can be obtained from our publishing department. The best Willows for basket-making are the purple Osier (Salix purpurea), S. viminalis and S. triandra. Probably the most valuable is S. viminalis. Willows will not succeed well in peaty, sandy, or water-logged soil—rich, well-drained loam that can be flooded at will being most suitable. Prepare the ground by trenching or ploughing, and thoroughly cleanse it from weeds. Insert the cuttings from November to March, avoiding such as are bark-chafed, and make the soil about them firm. Keep the beds clean and free from weeds. The cost of forming Osier beds varies from £15 to £20 an acre. The crop matures in about four years, and yields, on an average, £15 an acre

WIREWORM IN SOIL: *T. H.* and *A. W.* This pest is difficult to destroy in the case of land on which vegetation is growing. The best plan is to apply a dressing of "Vaporite" now, and then dress the land with gas lime in the autumn when the crops are harvested. "Vaporite" can be obtained from the horticultural Sundriesmen.

THE FLOWERS OF SPENSER.

WE have four great pre-Elizabethan and Elizabethan poets: Gower (1320 (?)-1402), Chaucer (1328-1400), Spenser (1553-1599), and Shakespeare (1564-1616). Like all English poets, each of the four has something to say about flowers, but he says it in his own peculiar way; Gower, as might be expected from his constant residence in London, mentions only between thirty and forty plants, and of these he gives little beyond the names; in no case does he at all describe them. Chaucer is very different; he delighted in the country and in all country sights and sounds. The number of plants he mentions is not great, but where he mentions them, he does so as if he had closely observed them and loved them; nothing has been written that at all approaches his supreme delight in the Rose and the Daisy. Spenser surpasses Chaucer in the number of the plants named, but is far behind Shakespeare, and the different way in which the two poets speak of flowers is very marked. Shakespeare noted the flowers he met with in his daily walks and gathered them, not because he wanted them in his poetry, but because they met him as he walked, and he loved them. Spenser also noted the flowers, but the flowers he gathered were not those that he saw in the fields or gardens, but they were for the most part culled from his reading in the Latin and Greek classics. In fact, with few exceptions, he seems to have cared little for any flower or plant if it had not the hall mark of some well-known classic. Even in such a poem as the "Shepheard's Calender," where we might have expected English scenery peopled by English workmen, the scene is more suggestive of Sicily and Italy than of England; and we seem to be listening to Theocritus and Virgil rather than to an Englishman. Still, with all these drawbacks, I think the flowers of Spenser are worth studying, and I have written the following paper in the endeavour to determine what special flowers he had in his mind when he wrote about them. The account of the flowers does not profess to be a positive or scientific account; and the papers are rather an annotated index, or perhaps a concordance. I have quoted, but as shortly as possible, his allusion to each plant, and added short notes on those of them that seemed to require it. The work has been to me very pleasant, and I hope the result may be pleasant and useful to those who feel an interest in the gardens of our forefathers, as well as to students of Spenser.

The edition from which I have quoted is Pickering's "Aldine Poets" edition in five volumes, published in 1839.

ALDER.

1. Keeping my sheepe amongst the cooly shade
Of the green Alders by the *Mullaes* shore.
Colin Clout, 58.

2. Catching hastie holde
Of a young Alder hard beside him pight.
Virgils Gnat, 58.

The Alder is a native British tree, and has had its present name certainly since the seventh century, yet, as in most of its European names, it comes from the Latin *Alnus*. It is a water-loving tree, and the wood is said to be indestructible under water, so that the Rialto at Venice is traditionally said to be built on piles of Alder. The prehistoric Glastonbury was built on piles of Alder; the remains still exist and are fairly sound.

ALMOND.

Like to an Almond tree ymounted hye,
With blossoms brave bedecked daintily.
F.Q., I. vii. 32.

Though the Almond bears a Greek name which, in different forms, is found in all European languages, yet it is not a European tree, but is native in Western Asia. The ease with which it is raised from the ripe kernels soon led to its growth all through Southern Europe, and both fruit and tree were known in England in very early times. In Spenser's day it was grown in English gardens, and has always been popular from its beauty in early spring and its Biblical associations.

AMARANTH.

Sad Amaranthus made a flower but late—
Sad Amaranthus, in whose purple gore
Me seemes I see Amintas wretched fate.
F.Q., III. vi. 45.

Dr. Murray defines Amaranth as "an imaginary flower reputed never to fade; a fadeless flower (as a poetic conception)"—and this describes the flower as named in Latin, Greek and English poets. But I think Spenser, by speaking of its "purple gore," had some special plant in view, but it is almost impossible to say what. It could not have been any of the plants now called Amarantus, which include "Love-lies-bleeding" and "Prince's Feathers," for they were introduced after Spenser's day. Amyntas is named by Virgil in several places as a lover, but nothing more is said of him. In Spenser, Amyntas is supposed to be the celebrated Earl of Derby, who died in 1594.

APPLE.

Like as a withered tree, through husband's toyle,
Is often seene full freshly to have florisht,
And fruitful apples to have borne awhile—
F.Q., IV. iii. 29.

Apples here only mean fruit of any sort; as was the common use of the word in the sixteenth century.

ASH.

The Ash for nothing ill. *F.Q., I. i. 9.*

Ovid, in the Metamorphoses, Book X., gives a list of trees with short descriptive epithets, from which Spenser evidently took his list of trees in this passage. Ovid's description is "Fraxinus utilis hastis," which Spenser enlarged to "for nothing ill."

ASPEN.

1. The Aspene good for staves. *F.Q., I. i. 8.*
2. his hand did quake
And tremble like a leafe of Aspen greene.
F.Q., I. ix. 51.

The Aspen is a Poplar, but it has been called Aspe or Aspen in England from the earliest time. The tremulous character of the leaves has been a favourite subject for similes with hundreds of English writers.

ASTROPHEL.

Feede ye henceforth on bitter Astrophell.
Daphnaida, 346.

The name has long been obsolete, and the plant has not been identified; but is conjectured to be the wild Aster of our marshes.

BALM.

Embathed Balme. *Muiopotmos, st. 25.*

The writers of Spenser's time, when speaking of balm, generally meant the imported drug; but as Spenser places it amongst many other sweet-scented flowers and calls it embathed, i.e., bathed in perfume, he was probably thinking of the Bastard Balm (Melittis Melissophyllum), which is found wild in a few places in the southern counties, and is a handsome plant, but the scent is found more in the dried leaves than in the living flowers.

BARLEY.

Which cockle for corne, and chaffe for barley bare.
Shepheards Calender, December.

BASIL.

Bazil hartie-hale. *Muiopotmos, st. 25.*

Basil is an Eastern plant (*Ocimum*), but was grown in England from very early times. Though it did not rank so high as its name, from Greek *basilicon*, i.e., royal, would suggest it was in high repute as a pot-herb, so that Gerarde says of it: "It taketh away sorrowfulnesse, and maketh a man merry and glad." *H. N. Ellacombe.*

(To be continued.)

NEW OR NOTEWORTHY PLANTS.

AN OVERLOOKED *MALVASTRUM.

THE Malvastrum shown in fig. 176 has been cultivated in Britain for at least a century, but has hitherto remained undescribed. It is allied to Malvastrum divaricatum, Gray and Harv., from which it differs in the serration of the leaves and the perfectly glabrous lower part of the ovary—whence the name, M. hypomadarum. Perhaps the earliest specimen of it in the Kew Herbarium is one from the herbarium of the well-known botanist, Dr. Samuel Goodenough, one of the founders of the Linnean Society, and Bishop of Carlisle, in compliment to whom the genus Goodenia was named. Goodenough's herbarium, which was presented to Kew in 1880 by the Mayor and Corporation of Carlisle, comprises not only the various species which he was the first to describe, but an extensive selection of the plants which were cultivated at Kew in the beginning of the nineteenth century, and published in the *Hortus Kewensis* (*Kew Report*, 1880, p. 64).

Goodenough's specimen of Malvastrum hypomadarum is labelled "Malva africana; Kew; an sp. nov.?" but this name does not appear in either edition of the *Hortus Kewensis*. A "Malva africana, Mill.," however, appears in Steudel's Nomenclator, and is reduced to Malvastrum capense in the *Index Kewensis*, and Goodenough's specimen was subsequently referred doubtfully to the latter species, from which it differs in the cutting of the leaves and the long stellate bristles at the apex of the carpels.

In 1810 Malvastrum hypomadarum was cultivated as "Malva capensis" in the Liverpool Botanic Garden, and it has since passed in gardens under the names Malvastrum capense, M. virgatum, and M. grossulariæfolium (see specimens in the Kew Herbarium). A specimen of it in Bentham's herbarium is labelled as received from G. A. Walker Arnott in 1827 under the name Malva divaricata, and was referred by Bentham to Malvastrum tridactylites, which may be distinguished by its perfectly glabrous carpels. M. hypomadarum, therefore, has passed under the names of at least five species of Malvastrum, with none of which it agrees.

The specimen figured was communicated for the purpose by Messrs. James Veitch & Sons, Ltd., who received cuttings of the species from the Royal Botanic Gardens, Glasnevin, whither it had come from the Royal Botanic Garden, Edinburgh.

M. hypomadarum is a free-flowering shrub, 2 or 3 feet high, with long slender branches, which are rather densely pubescent with stellate hairs. The stipules spread horizontally, and are obliquely lanceolate and ciliate. The leaves show considerable variation in size, shape and cutting, being usually deeply three-lobed, the middle lobe considerably longer than the lateral ones, and all the lobes slightly narrowed to their base and sharply toothed or serrate above, rarely toothed below also, as in the figure; the base of the leaf is conspicuously wedge-shaped. Forms sometimes occur, however, as in the specimen figured, where the leaf is much less deeply divided, and in which indications of two additional side lobes appear, so that the leaf is imperfectly five-lobed, and in correlation with this the base of the leaf becomes much more obtuse; in the uppermost leaf of the figure, however, the wedge-shaped base may be made out. Both surfaces of the leaf are softly and sparsely pubescent with stellate and simple hairs, and the veins are impressed on the upper surface and prominent on the lower.

The peduncles bear from one to three flowers, and are suppressed in the upper part of the stem, so that the flowers often arise two together in each axil, as in the illustration. In the same axils as the peduncles there arise one or two accessory leafy branchlets, 3 inches long or less, which in their turn produce flowers, after those on the primary peduncle have withered. In this way, branches 18 inches long or more may bear flowers of about the same age along their whole length, those on the upper part being borne on the primary peduncles, and those on the lower on the leafy branchlets. The three bracts, which arise immediately below the calyx, are spathulate-linear, ciliate, and puberulous outside. The calyx-lobes are ovate, acuminate and ciliate, three-nerved or indistinctly five-nerved, and are twice as long as the calyx-tube. The corolla varies a good deal in size, being about an inch and a half across in well-developed flowers, and often considerably less. The obliquely obovate, retuse petals are white, with a rose-purple blotch near the base. The staminal tube has a dense band of hyaline stellate hairs about the middle; in the diagrammatic longitudinal section these hairs, as well as those on top of the ovary, have been omitted for the sake of clearness. The anthers are crowded in a subglobose head, overtopped by the stigmas, as in other species of Malvastrum.

FIG. 176.—MALVASTRUM HYPOMADARUM SP. NOV.
(From specimens exhibited by Messrs. Jas. Veitch & Sons.)

* MALVASTRUM HYPOMADARUM (*Sprague*), SP. NOV.—Affinis M. divaricato, Gray et Harv., a quo foliis serratis nec crenatis, carpellis apice tantum stellato hirsutis ceterum calvis differt. Frutex vix 1 m. altus, ramis gracilibus densiuscule stellato-pubescentibus. Stipulæ patentes, oblique lanceolatæ, 3-5 mm. longæ, ciliatæ. Petioli circiter 6 mm. longi. Folia trilobata, 2.5-4 cm. longa et subæquilata, basi conspicue cuneata, utrinque pilis simplicibus et stellatis parce molliter pubescentia, nervis supra impressis subtus prominentibus, lobis oblongis vel in basin angustatis, medio quam lateralibus majore, dentato-serratis præsertim superne, dentibus interioribus patulis vel leviter retro curvatis. Pedunculi 1-3-flori, ei axillarum superiorum plus minus contracti, inferiorum usque ad 1.3 cm. longi, omnes ut pedicelli calycesque extra stellato-pubescentes. Ramuli accessorii 1 vel 2 ex iisdem axillis orti, 4-7 cm. longi, foliati, 2-5 flori. Pedicelli 1.3-2 cm longi, 3 mm. infra apices articulati. Bracteæ spathulato-lineares, 6-8 mm. longæ, 1 mm. latæ, longe ciliatæ, extra puberulæ, intra glabræ. Calyx intus minute appresse pubescens; tubus 3 mm. longus, circiter 20-nervius; lobi ovati, acuminati, 6 mm. longi, trinervii vel indistincte quinquenervii, ciliati, nervis lateralibus in tubum separatim currentibus. Corolla 2.5-4 cm. diametro; petala oblique obovata, retusa, alba, circa basin purpureo-maculata, inferne dense ciliata, intus infra stellato-pubescentia vel puberula. Columna staminea tota 1 cm. supra insertionem petalorum producta, medio dense stellato-hirsuta. Carpella apice longe stellato-hirsuta, ceterum glabra; stylus 1.5 mm. supra basin articulatus, ramis purpureis.—Planta capensis, per sacculum in hortis anglicis culta, loco natali exacto incognito.

The pollen grains, as in all Malvaceæ, are prickly and form an interesting object for the microscope; the Bombacaceæ or Silk-cotton Tree family, which were formerly included with the Malvaceæ, have smooth pollen, and are now separated from them, partly on that account. The carpels are ten in number, one opposite each sepal and petal, and are quite glabrous except at the top, where they are densely covered with rather long, hyaline, stellate bristles. The ripe fruit is not known.

The writer is indebted to Messrs. James Veitch & Sons for the excellent specimens from which the description of Malvastrum hypomadarum has been drawn up, also for the following notes on its cultivation:—"It may be propagated by means of cuttings placed under a hand-light in May or June; these will flower the following season in a cool greenhouse. It succeeds best potted in a light turfy loam to which an equal proportion of either peat or leaf-mould is added with a sprinkling of silver sand. It flowers best when kept in moderately small pots, and lasts in flower for several weeks."

The systematic relationships of Malvastrum hypomadarum seem to be rather complex. In addition to the close relationship, already mentioned, with Malvastrum divaricatum, Gray and Harv., it appears to have affinities in two directions. On the one hand, the similarity in the habit and lobing of the leaves of M. tridactylites is sometimes so great that it is hardly possible to distinguish the two species without dissection; and it is quite possible that this is really its nearest affinity. On the other hand, there is an obvious relationship with two as yet undescribed species collected by Dr. R. C. Alexander (afterwards Prior) in the George District of Cape Colony. One of them was collected by him in Lange Kloof in November, 1847; it may be distinguished by the purple bracts and purple margins of the calyx-lobes, as well as by the firmer texture and the shape of the leaves, and the more densely hirsute carpels. This was collected along with Malvastrum Alexandri (E. G. Baker, in *Journal of Botany*, 1891, p. 166) by Alexander, who took them for the same thing, and mounted them on the same sheet in his herbarium as Malvastrum tridactylites. M. Alexandri may be distinguished at once, however, by the perfectly glabrous staminal tube, as already noted by E. G. Baker. A glabrous staminal tube occurs in two other South African species only, M. albens, Harv., and Malva divaricata, Andrews.

The second undescribed species was collected near Warnhop on the Zwartberg Range. Both are in the Kew Herbarium.

As will be gathered from what has been said, the South African Malvastra are extremely critical, and stand in great need of revision. The genus Malvastrum was established by Asa Gray in 1849 (*Plantæ Fendlerianæ*, p. 21), and can be distinguished from all other Malveæ by the single whorl of carpels, the solitary ascending ovule, the capitate or truncate stigmas, and the free peduncles. The involucral leaflets are three in the South African species, and often afford useful diagnostic characters. Although placed in the sub-tribe Enmalveæ, it appears to be most nearly related to Sphæralcea, which is put in the sub-tribe Abutileæ on account of having two or three ovules in each cell; and it does not seem possible to distinguish the two genera without dissection.

In 1857 Garcke pointed out (*Bonplandia*, vol. v., p. 296), that all the species of De Candolle's sixth section of Malva, the "Capensis" (*DC. Prodromus*, vol. i., p. 433) belonged to Malvastrum; and in 1859 or 1860 Harvey redescribed them under that genus in the *Flora Capensis*, vol. i., pp. 159-164. Harvey's revision was severely criticised by Garcke in 1864 (*Botanische Zeitung*, vol. xxii., pp. 10-11), partly on the ground that the primary division into fruticose and suffruticose species was unworkable in practice, and partly because Harvey's identifications of some of Cavanilles's species of Malva were wrong in his opinion. He stated that Malvastrum grossulariæfolium, Gray and Harv., was certainly distinct from Malva grossulariæfolia, Cav., as it did not agree with the figures in Dillenius's *Hortus Elthamensis*, t. 169, fig. 207, and in Cavanilles's *Dissertationes*, t. 24, fig. 2, but with Malva triloba, Thunb.; and he accordingly renamed the species Malvastrum trilobum, Garcke. So far, he may have been right, but his further identification of Malvastrum albens, Harv., with Malva grossulariæfolia, Cav., seems untenable. A careful botanist such as Cavanilles would certainly have noticed the *glabrous* staminal column of Malvastrum albens had he been describing that species, whereas in his description of Malva grossulariæfolia (*Dissertationes*, p. 71), he writes of the staminal tube, "Reliqua ut in præcedenti," that it is to say *villous* below, as in Malva virgata. I am also unable to follow Garcke in his reduction of Malvastrum setosum to M. tridactylites, although the two species are doubtless closely allied.

In 1891 E. G. Baker described four new South African species of Malvastrum in his Synopsis of Genera and Species of Malveæ (*Journal of Botany*, 1891, p. 165). Writing in the days before the publication of the *Index Kewensis*, he not unnaturally overlooked Garcke's little-known paper, and his account of the previously-described species differs little from that of Harvey in the *Flora Capensis*, the division into "Fruticosa" and "Suffruticosa" being retained. Malvastrum fragrans is reduced by him to M. capense, however, and Malva retusa, Cav., is definitely transferred to Malvastrum, where it is placed between M. albens and M. divaricatum.

Co-ordinating the results attained by Harvey, Garcke, and Baker, the following list of the South African species is obtained:—(1) fragrans, Gray and Harv.; (2) capense, Garcke; (3) calycinum, Garcke; (4) strictum, Gray and Harv.; (5) asperrimum, Garcke; (6) trilobum, Garcke; (7) bryonifolium, Garcke; (8) virgatum, Gray and Harv.; (9) tridactylites, Gray and Harv.; (10) setosum, Harv.; (11) albens, Harv.; (12) divaricatum, Gray and Harv.; (13) racemosum, Harv.; (14) procumbens, Harv.; (15) dissectum, Harv.; (16) retusum, E. G. Baker; (17) trilobatum, E. G. Baker; (18) Burchellii, E. G. Baker; (19) Pappei, E. G. Baker; (20) Alexandri, E. G. Baker; (21) hypomadarum, Sprague. No attempt has here been made to arrange the species in order of supposed relationship, but the first 15 correspond to those described by Harvey, and the remaining six are those since added. It should be noted that Malvastrum divaricatum, Gray and Harv., is certainly distinct from Malva divaricata, Andrews, the former having a villous, the latter a glabrous, staminal tube. I have seen no specimens corresponding to Andrews's figure and description, and have not included the species in my list. *T. A. Sprague.*

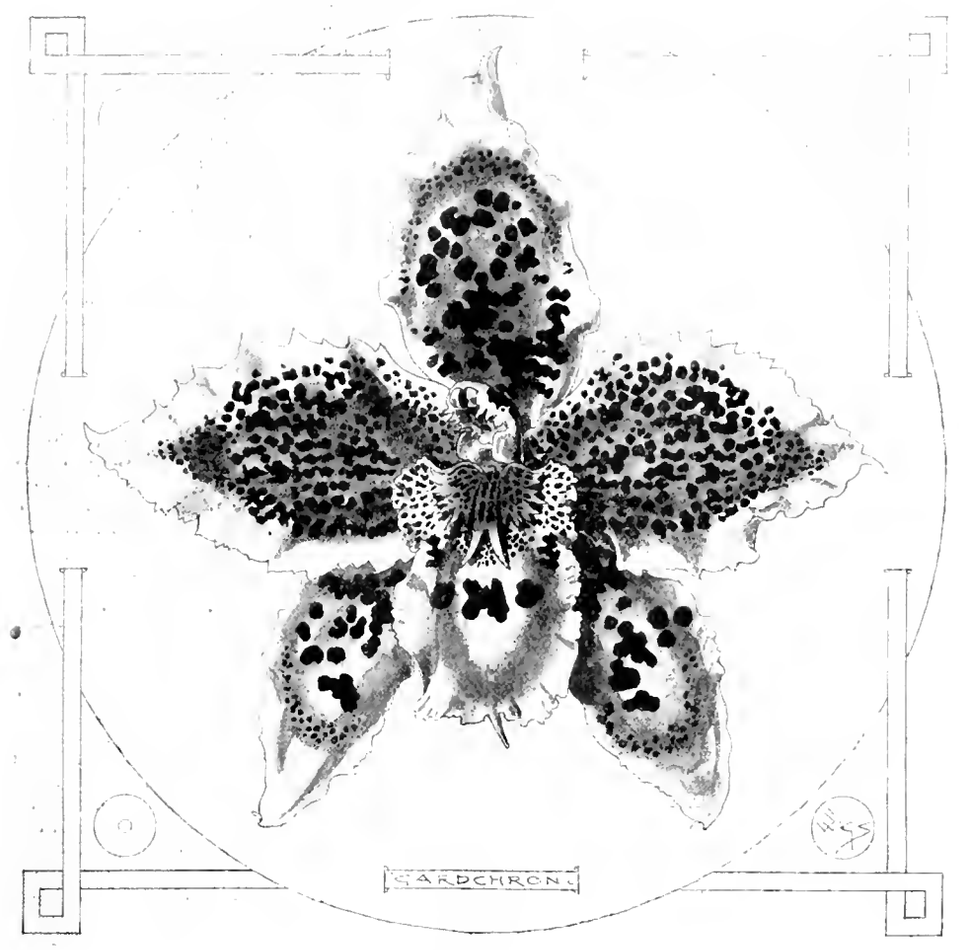

FIG. 177.—ODONTOGLOSSUM PERCULTUM VAR. J. R. ROBERTS.

ODONTOGLOSSUM PERCULTUM VAR. J. R. ROBERTS.

AT the meeting of the Royal Horticultural Society on March 31 last J. Gurney Fowler, Esq., Glebelands, South Woodford (gr. Mr. J. Davis), obtained an Award of Merit for a plant of this beautiful Odontoglossum. The charm of the flower is largely due to its exquisite colouring. The large, flatly-displayed petals and sepals are coloured with a suffusion of pink that is brought into relief by a broad band of white around the margins of the segments. There are dense purple spottings on the inner parts of the segments; the lip is large, white, with rose-purple markings on the basal half.

BELGIAN HORTICULTURE.

MONS. A. A. PEETERS, BRUSSELS.

AT the end of April we paid a visit to Mons. Peeters' Orchid establishments. At the Home Nursery, situated in a suburb of Brussels, all the Orchids are cultivated for supplying blooms for cutting. The visitor is surprised to learn this as he passes through house after house containing different species, including many Cattleyas, for some of the cultures appear so expensive that the sale of the flowers would hardly seem to be remunerative, but there appears to be a demand for considerable quantities of cut flowers of the most costly type. In one house, for instance, there were hundreds of plants of Vanda cœrulea and other species that are certainly not often regarded as market plants. Madame Peeters, who, by the way, is a native of Suffolk, acted as our guide on this occasion, and informed us that the flowers are sent principally to the markets at Brussels and Paris. In the latter city especially the demand for expensive Orchid flowers is considerable.

Mons. Peeters, however, is best known by reason of the superb blotched varieties of Odontoglossum crispum that he has introduced to commerce. Therefore, after a somewhat hurried inspection of the cut flower plants, we drove to the other nursery, situated at a greater distance from the city of Brussels, and, therefore, in a clearer atmosphere, for Mons. Peeters would not care to subject the more valuable plants to the conditions prevailing in the city. The collection at this latter nursery is a very fine one. Cattleyas and Lælio-Cattleyas, Cypripediums and Phalænopsis, Odontoglossums, and others are grown in large quantities, and with the greatest success, and many fine varieties were in bloom. The Odontoglossums, however, attracted us most, partly on account of the rapid progress which is being made in raising these beautiful Orchids from seed, and partly because of the number of striking plants in flower.

There were seven long houses, mostly devoted to Odontoglossums, and in several of them we observed as many as 200 beautiful forms in flower. Odontoglossum Lambeauianum furnished a wealth of variation, and it was at first difficult to realise that such an amount of difference was possible between seedlings from the same capsule. There were forms with both white and rosy grounds, with few or many large or small spots, and forms more or less dotted or marbled, with an equally wide range of differences in shape and in the details of the lip, yet there were points of resemblance in many cases between them, and a numbered label in each pot helped one greatly in identifying them. These numbers have been applied very carefully, and it gave one the greatest satisfaction to see the origin of the plants so carefully recorded. Many of the plants from this batch were very handsome.

A batch of Odontoglossum Fas inator was even more remarkable, for it showed not only forms with white and rosy ground, but various shades of yellow, while the variation in size and the amount of spotting were equally wide. This batch of seedlings was raised from Odontoglossum Adrianæ (Hunnewellianum × crispum) crossed with a blotched form of O. crispum, and the yellow forms show a reversion to the ground colour of the original O. Hunnewellianum. Some of them were very good in form, and exquisitely marked.

Various seedlings obtained by inter-crossing fine forms of Odontoglossum crispum included some handsomely-blotched varieties, a batch from O. c. Mariæ × O. c. Luciani being very variable, and one almost suffused throughout with colour. Other seedlings from blotched crispums are coming on, and by this means the number of these beautiful forms is being steadily increased. Other valuable plants were some very richly-coloured varieties of O. Hallio-crispum, a plant of the original O. Wilckeanum albens (which, of course, came as an imported plant); a seedling from O. triumphans crossed with O. excellens Prince of Orange, and most resembling the former, a very bright yellow seedling from O. triumphans × polyxanthum, O. loochristiense, and numerous others, with a quantity of the well-known species which flower at this season.

One of the houses was being largely utilised for propagating choice forms of O. crispum and others from ba k pseudo-bulbs, and in another we noted batches of numerous interesting crosses in various stages, from the tiniest globules upwards, in some cases the compost being literally covered with germinating seedlings. The choicest forms obtainable are used for crossing, and the results will doubtless be known in due time. A number of Cochlioda crosses were also growing freely, but this remark does not apply in every case, for a few plants of C. Nœtzliana crossed with both Odontoglossum crispum Cooksoniæ and with O. Lambeauianum make very slow progress. Other evidence of hybridising operations in progress was observable in the number of capsules in various stages on the plants.

There were, of course, batches of imported Odontoglossums, but the centre of interest has now been transferred to the seedlings, and we passed through them quickly, observing, however, some good forms coming into flower.

A very interesting plant was here pointed out, namely, one of the original Oncidium Leopoldianum, for which £20 was paid a good many years ago, but which still refuses to flower. It proves to be a bad grower—at all events, no means of successful treatment has been discovered. Only two or three other plants are known, and the one which flowered a few years ago in the collection of E. Ashworth, Esq., proved to be Oncidium corynephorum, Lindl., a fact which gives additional interest to the few remaining ones. It is hoped that one of these days this plant will acquire enough strength to flower, but a little more patience will have to be exercised.

M. Peeters may be congratulated not only on his success in raising and growing these beautiful plants, but also on the careful records of parentage he maintains, which should afford some valuable information later on.

NOTES ON IRISES.

IRIS MINUTA.—The yellow variety of this Iris, which is noticed by Baker in his handbook of the Irideæ, flowered here for the first time on May 4. It agrees with the type in all respects, except in colour, which is a bright yellow. The falls are marked with fine brown dots and lines down the haft and centre of the blade, and the edges of the standards are also brown. The plants were imported from Japan.

IRIS KUMAONENSIS CAULESCENS.—A few months ago I received from Messrs. Barr & Sons a small piece of the rootstock of an Iris, with a note to the effect that it came from the Sikkim Himalaya. In appearance the rootstock resembled that of I. Duthiei, and I therefore planted it in a stony soil rich in humus, adding a little peat. The first flower opened on May 11th, and proved that the Iris was a variety of kumaonensis, distinguished from the type by having a stem nearly 6 inches long. The standards, of a pale mauve-lilac, are not held erect, but incline outwards, giving the flower a likeness in shape to I. tectorum. The falls are of a deep purple-lilac, mottled with a still deeper shade, while the deep orange tips to the fine white hairs of the beard are a distinct feature. The flower, unfortunately, only lasts for 12 hours, but 36 hours after it fades the second flower is fully expanded. The following is a detailed description:—Rhizome slender, short-creeping; tufts crowded; outer sheaths splitting up into fine fibres. Leaves linear, pale green, rigid, 4 to 6 inches long by ⅓rd inch broad at flowering time. Peduncle 4 inches long, one-headed. Spathes two-flowered; valve lanceolate, pale green, 2 inches long; pedicles very short. Perianth tube 1½ inches long, dark purple; falls obovate-cuneate, 2 inches long, the outer 1¼ inches reflexed, 1 inch broad, dark purple lilac mottled in the centre of the blade with a darker shade; beard of fine white hairs tipped deep orange, arising from a white crest; standards spreading, oblong-unguiculate, 2 inches long ¾ inch broad, pale mauve-lilac; crests deltoid.

THE CULTURE OF ONCOCYCLUS IRISES.—Everyone who has ever grown these beautiful Irises knows the difficulties under which they are cultivated. The chief of these perhaps arises from the fact that, whether the rhizomes are in or out of the ground, they begin to develop shoots in October. They must, therefore, be planted in the autumn, and our variable winters play sad havoc with the young leaves, and the percentage of losses among a number of these plants is often high. In their homes in Central Asia these Irises are frozen hard all through the winter, and cannot grow until the snow melts in spring. In order to reproduce these conditions as nearly as possible, I packed up a number of rhizomes last August in dry moss in a wooden box, and sent it up to the Imperial Cold Stores Co., at South Tottenham. There the box remained in a temperature of 28° to 30° until the first week in March. On opening the box then the roots were precisely as they had been in August. I planted the rhizomes on March 9, and the plants soon made healthy growth in warm, sandy soil, with a layer of old cow manure a foot beneath the surface. The buds are now showing, and the plants apparently in the best of health. *W. R. Dykes, Charterhouse, Godalming.*

CONTINENTAL NOVELTIES.

TWO NEW PINKS.

THE number of varieties of white Pinks is large enough in all conscience, and every gardener is acquainted with Mrs. Sinkins, Her Majesty, Bridesmaid, The Bride, Diamond, La Reine, &c., and many coloured varieties. Apart from the common, small-flowered Feathered Pinks, almost every one of the coloured Pinks in commerce, such as Rose de Mai, Cattleya, Early Blush, La France, Excelsior, &c., has one or more faults; the blooms are either too small, the colour not clear, or pleasing, the calyx bursts too early, they bloom too sparingly, or the flower stem is short and weak, so that the blooms fall upon the ground. It is said that none of these blemishes are met with in the new Feather Pinks Delicata and Gloriosa, raised by a gardener in a Saxon hill-town, and which are to be distributed this year by the firm of Otto Mann, of Leipzig-Eutritzsch. These two varieties are the products of a cross of Diamond (Diamant) and Rose de Mai, and were selected from amongst 30 different seedlings. The flowers possess beauty of colouring, pleasing form, and unusual size for a Feather Pink. The flower-stalk is of great length and strength. Delicata is of a very distinct Cattleya-like colour, in the centre of a pale creamy-white, without any zone or trace of any; it is 2½ to 3 inches in diameter, semi-globular in shape, and with stems 1¼ feet high. Gloriosa is the earliest to flower, which it does at the end of May in the open air. The stems are of the same height as those of Delicata. The colour is clear lilac-rose, and the flower is without a zone. The variety is an abundant bloomer. *F. M.*

TREES AND SHRUBS.

SHRUBBY SPIRÆAS.

It is doubtful whether any genus of flowering shrubs has such a lengthened season of blooming as the Spiræa, provided that a judicious selection of species and varieties is made.

Spiræa Thunbergii unfolds its tiny white blossoms quite early in the spring, and from that time forward a succession of different kinds is kept up till the frosts of autumn appear. Among the latest to flower are the dwarf forms of S. japonica (S. callosa of gardens), the white-flowered variety alba being particularly noticeable in this respect.

The list of original species and garden forms in cultivation is a lengthened one, hence in gardens of limited extent a careful selection is absolutely necessary.

Opinions vary considerably, and any selection, however thoughtfully made, is not likely to meet with the approval of everyone, but the following series will, I think, be difficult to improve upon :—

SPIRÆA AITCHISONII (see fig. 178).—This is one of the pinnate-leaved species, being a native of Afghanistan. For some years it was confounded with the better-known S. Lindleyana, from which it differs in the whiter flowers, the leaves of a deeper green, and the reddish colour of its stems, as well as in other minor features. A writer in the *Gardeners' Chronicle* for January 18 last, directs attention to this Spiræa so fully that nothing further need be said concerning it.

SPIRÆA ARGUTA (see fig. 179).—Like the preceding, this species is of comparatively recent introduction, but it has become very popular within the past few years. This was to be expected, for it is one of the best of the early-blooming Spiræas, and forms a delightful flowering bush from 4 feet to 6 feet high, and is the same distance through. The branches are slender yet twiggy, and are disposed in a graceful manner. The flowers are arranged in clusters on the upper sides of the shoots, and so numerous are they that when at their best a bush of this Spiræa is quite a mass of white. It flowers, as a rule, towards the end of April, and it possesses the great merit of being less affected by late spring frosts than many other flowering shrubs. This Spiræa is also valuable for flowering under glass early in the year.

SPIRÆA BRACTEATA (see fig. 180).—A freely-branched shrub 5 feet in height or thereabouts, and flowering towards the end of May and in June. The flowers are white, and are borne in flattened clusters, which extend for a considerable distance along the shoots. It is a native of Japan.

SPIRÆA CANESCENS.—A Himalayan plant which, in the *Kew Hand List of Trees and Shrubs*, is provided with a longer list of synonyms than any other species. In habit of growth it is quite distinct from many other Spiræas, the main shoots being more or less upright, while the secondary ones droop gracefully on all sides. In a vigorous specimen the branches are of considerable length, and during the flowering period are thickly studded for some distance with little flat clusters of white blossoms. This Spiræa flowers from the end of June onwards. One of its synonyms is S. flagelliformis, and as such it is more often met with in gardens than under the specific name of canescens.

SPIRÆA DISCOLOR, SYN. S. ARIÆFOLIA.—This is a large-growing species that sometimes forms a bush as much as 10 feet in height. The creamy-white flowers are borne in large plume-like masses. They are at their best in July, at which time this Spiræa is fully entitled to rank among the very finest of flowering shrubs. It is a native of North-West America. *W.*

(To be continued).

THE FERNERY.

FERN SPORES.

To those who have mastered the principles governing success in Fern spore sowing, the operation is extremely interesting, especially if good varietal forms are concerned, for they are very liable to vary again and thus to give rise to further new and improved types. Every Fern genus has its own peculiar way of bearing its sporangia, and however much the species or varieties which comprise the genus may differ, the same character will be evident in all. Thus, for instance, if we examine the common Polypody (Polypodium vulgare) we shall find the frond backs dotted with large golden-yellow sporangium heaps, round or, it may be, oval and devoid of anything in the nature of a cover. Close by, in the same wall or hedgebank, we may find the Black Maidenhair Spleenwort (Asplenium adiantum-nigrum), and on the backs of its fronds we find long black lines arranged herring-bone fashion, these consisting of long heaps of sporangia, which are, moreover, partly covered with a thin skin springing from one side of the linear heap. Now there are great numbers of Ferns in the world which bear their sporangia in these ways, *i.e.*, in uncovered roundish heaps and covered longish lines, arranged as described, but whenever we see them we shall be justified in calling the first a Polypodium and the second a Spleenwort. We turn to the common Bracken (Pteris aquilina), and we find a third variant, for here the sporangia lie along the edges of the sub-divisions, and are covered by the edge being turned down over them. Every such Fern is a Pteris. Some Ferns, such as the Royal Fern (Osmunda regalis), have their sporangia confined to the tips of the fronds, where so much energy is devoted to their construction that none is left for leaf building, and the result is a contracted Spiræa-like mass of sporangial heaps. This type of spore bearing appears in several distinct genera, but is differently characterised in each. On examining the sporangial heaps of any class of Fern with a lens, we find them to consist not of bare, loose spores, capable of being shaken out like seeds from a ripe pod, but of an immense number of minute oval capsules attached to the frond by short stalks and densely massed

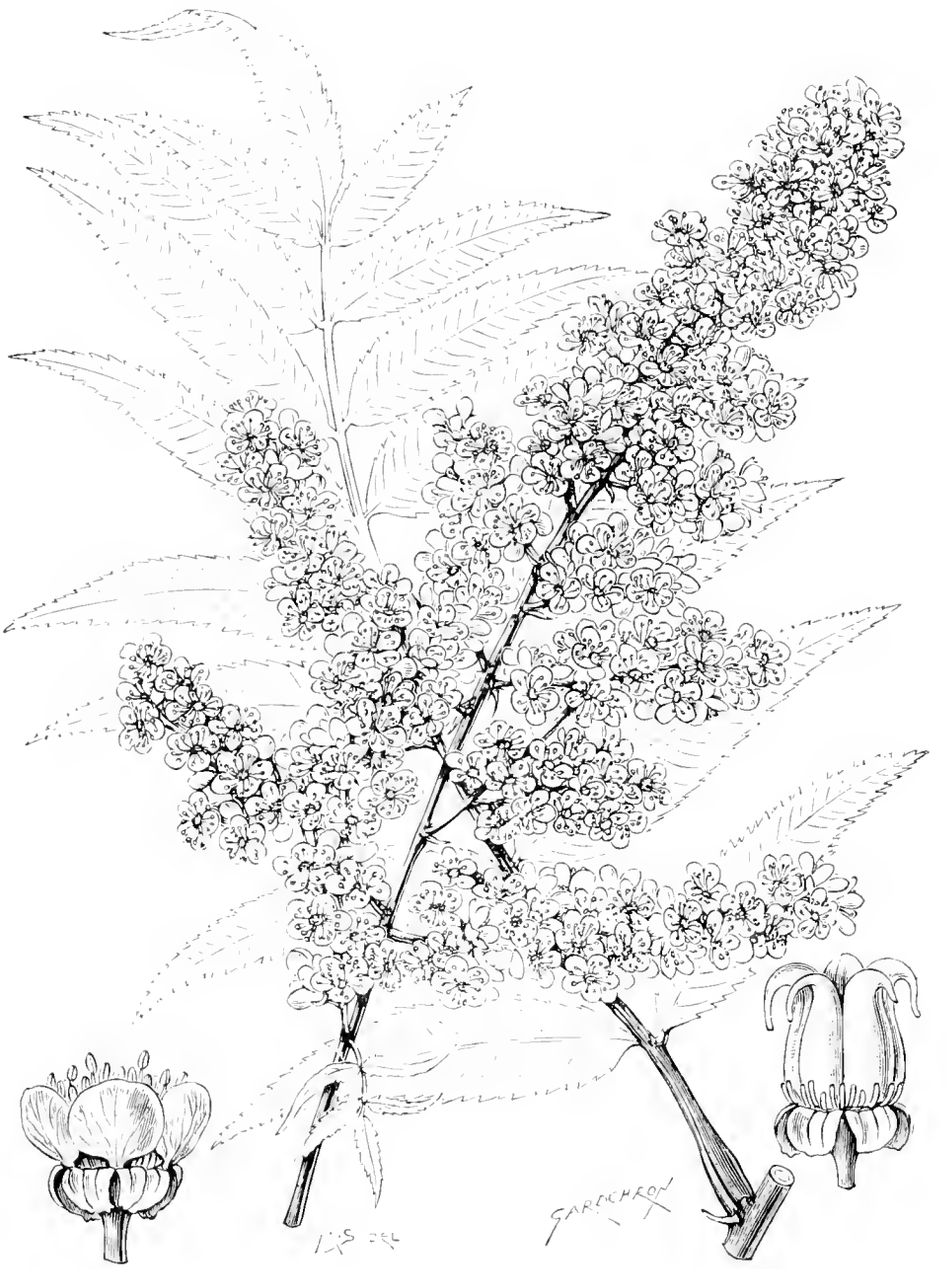

FIG. 178.—SPIRÆA AITCHISONII: FLOWERS WHITE, STEMS REDDISH.

together to the number of many thousands. If we scrape some of these capsules out on to a glass slip and place them under a microscope we may behold a most astonishing performance. Quiescent at first, the heap presently begins to move uneasily in twitches, and here and there we may see that this is caused by the capsules splitting on one side and slowly gaping, until the gape becomes an exaggerated yawn, showing the spores within. At this juncture, however, it is probable that the entire heap under observation will suddenly disappear as if blown away by dynamite, and on the clear space left we may see a rain, or rather hail, storm of far smaller bodies, which are the spores proper. Half-open capsules may be projected into the field of view, only to yawn a little wider and suddenly spring out of it with another hail shower. The fact is that, with few exceptions, the spore capsule is nearly surrounded with a ribbed band, and when the spores are ripe this band dries and shrinks so much that it tears open the front of the capsule, bends the top half back so as to expose the spores, and then suddenly doubles completely backwards, jerking the spores afar and itself to some distance by the recoil. This dislocation, however, only occurs when the spore cases have been removed from the frond as described; normally they merely burst and eject their spores then remaining attached to the frond, so that late in the season there may be nothing left but empty spore cases, a point to be remembered when sowing. We may now turn to the mode of collection for sowing, and as a general rule it may be said that the sooner they are collected and sown the better. As a rule, ripeness is indicated by the dark brown colour of the spore cases, but in Polypodium they are orange-yellow and in Osmunda olive-green. These are, however, rare exceptions. If time be precious, it may be noted that very often a few spore cases ripen long before the rest, and by noting and collecting these some weeks may be saved in the season. Each spore case contains a score or two of spores, and hence a very tiny portion of fertile frond affords an ample supply, a very minute pinch representing thousands of potential plants. Our own plan is to sever a small fertile portion, lay it back downwards on a glass slip, and leave it for an hour or two under a tumbler. On putting this slip then under a low-power microscope, we are able to judge of the quantity of spores shed and to be certain we are not merely sowing empty capsules. In fact, we know whether we are starting on a satisfactory basis or not. The next thing is to sow them, and here we must remember that although the annual spore crop of a single Fern may be hundreds of millions, it is abundantly evident that not one in a million succeeds in reproducing a Fern, even under congenial conditions; and that, therefore, the incipient germs must be peculiarly liable to perish. Worms and other animals, invading vegetation of other kinds, accidental floodings, &c., all upset the young beginners, and hence if we want a good crop we must take steps for their protection from these adverse influences. Having prepared small pots or pans with ordinary Fern compost, topped with a little loam, it is best to saturate this repeatedly with boiling water so as to kill all worms, germs, spores, &c.; and give our spores a fair field. The pots being cooled, we gently tap the glass slip aforesaid so as to distribute the spores very thinly and evenly over the surface. This being done, we cover with a glass slip and stow away in a cool, shady corner. A simple plan is to bed the little pots up to the edge in cocoanut fibre, packing them close in boxes or pans, and covering them with a frame of glass. All we have then to do is to keep the cocoanut fibre moist and await developments. In a week or two we may perceive a faint green tint appearing, showing the spores are germinating, and in time the whole surface becomes covered with small green heart-shaped scales, about the size of herring scales. If too thickly sown, it may be necessary to pinch out little patches of these into other pots or pans. The next thing, after a lapse of apparent inactivity, is the rapid appearance of tiny fronds springing from dents on one side of each scale, and after this it becomes purely a question of pricking out, potting in, and giving more and more room until specimen plants are acquired. Despite every care in collecting spores, it frequently happens that spores of other Ferns have previously been scattered over the fronds of the one desired, and hence when the youngsters appear the brood may be somewhat mixed. If so, the inferior ones should be *destroyed* as soon as recognisable, since the retention of inferior forms is bound eventually to be the bane of the collector, usurping valuable room and materially reducing the value of the collection. *Chas. T. Druery, V.M.H., F.L.S.*

NEW CHARACTER IN LEPTOSPERMUM SCOPARIUM.

LEPTOSPERMUM SCOPARIUM is a very common species in nearly all parts of the New Zealand botanical region, and occupies vast tracts of usually barren country, and it presents the unusual phenomenon of an indigenous plant becoming a "weed" in its own region, which shows, therefore, that the species is eminently adapted to changes of environment, and from such one might easily expect modifications to appear in one way or another. It flowers in great profusion, and at nearly all seasons of the year, and is conspicuous by the snowy whiteness of its flowers, so that any change of colour would easily be recognised should it occur. This has happened in several instances, especially in the north island of New Zealand, where I have observed individuals more or less deeply stained with pink in some of their parts; while

FIG. 179.—SPIRÆA ARGUTA: FLOWERS WHITE.

(For text see p. 397.)

there is a variety which is fairly abundant, the flowers of which are invariably stained with pale pink. In this form the colour is confined to the base of the petals, the calyx, the base of the filaments, the upper surface of the ovary, and the style and stigma.

Some years ago a plant was discovered in the south island with flowers of a bright rose colour, and it is now known in commerce as Leptospermum Chapmannii, and it has been found that this form produces itself fairly "true" from seed. I have seen a hedge of seedlings in Messrs. Nairn & Son's nursery in Christchurch where the most beautiful shades have been produced, many identical with the parent plant, while a few have reverted to the white form. Another point is the fact that the foliage of the pink-flowering plants differs from the ordinary in that it is of a brownish hue rather than green. Not long ago a remarkable individual plant was discovered growing on the sand hills a little north of Christchurch, and separated from the original habitat of L. Chapmannii by over 200 miles, which has blood-red flowers. This must have originated only a few years ago from these white-flowered forms, which alone are found in its immediate neighbourhood. It appears, therefore, that a plant has quite recently come into being which possesses a character non-existent in the parent plant, or, if present, has been for some time dormant. The foliage also of this plant is much darker, of a "Copper Beech" hue, and not green. Messrs. Nairn & Son again took this in hand, and have so far fixed it that a percentage of the seedlings come true, and they now possess a fair stock of this remarkable plant, which is quite distinct from the bright rose-coloured L. Chapmannii, not only in the colour of its flowers, but in the general habit of the plant, it being more drooping and slender, while its flowers are axillary and not terminal.

In conclusion, I would remark that this plant is now known as L. Nichollii, and is easily propagated by cuttings, and, from my observations of Leptospermum scoparium generally, I should say that it is a plant which might be much more generally grown in gardens in England than it is, and that it should be quite hardy here. *A. A. Dorrien Smith (Capt.)*

FLORISTS' FLOWERS.

THE POLYANTHUS.

CONSIDERABLE difference of opinion exists as to the best time for the sowing of the seeds of this plant. From 25 years' experience I find that to have them in bloom the following season they should be sown early in May. When this is done, the cultural requirements are different to those of plants raised from autumn-sown seeds. The seeds of Polyanthus, in common with all the species of Primula, germinate most quickly if they are sown as soon as they are ripe. If the seed is to be sown in the open border, now is a suitable time for the work, and it should be finished not later than the end of August. This will enable the seedlings to become established before winter, and they should not be removed till the following spring. Last year two plants that I wished to remove early in October had produced hundreds of healthy seedlings, and these I transferred to a portion of ground which I prepared for them, thinking they would become established before winter, but after every attention was paid them not 5 per cent. remained in the following spring. Other seedlings raised from seed sown in a box during the middle of September almost all survived the winter, the only protection being a sheltered position. Others, again, raised from a portion of the same seed in a box early in the year in a cold frame are now, in June, almost as forward as seedlings from seed sown in a warm frame early in March. *J. C.*

VEGETABLES.

WINTERING VEGETABLES.

DURING the next few weeks many vegetables will require to be planted in positions they will occupy during the winter, and upon the proper selection of the site depends in a great measure the success attending their culture. In my garden last season I planted Purple Sprouting Broccoli in two positions, the soil of which differed: in the one case it was loose and rich, and had borne a crop of early Potatos; the other plot was somewhat poor land, hard in texture. The plants on the rich land developed large, coarse heads and thick stems, whilst those on the other breadth appeared starved in comparison and the stems were very hard and woody. The inclement weather experienced during the first week of January proved a severe test to these plants, and two out of three on the rich soil perished, whilst not one in a hundred suffered on the poor land. This proves that vegetables should not be grown too soft and luxuriant if they are to withstand severe weather. I have noticed similar conditions in my Lettuces. In a neighbouring garden most of the green crops suffered from the cold of winter, but similar vegetables planted in an exposed field escaped unharmed. *John Crook.*

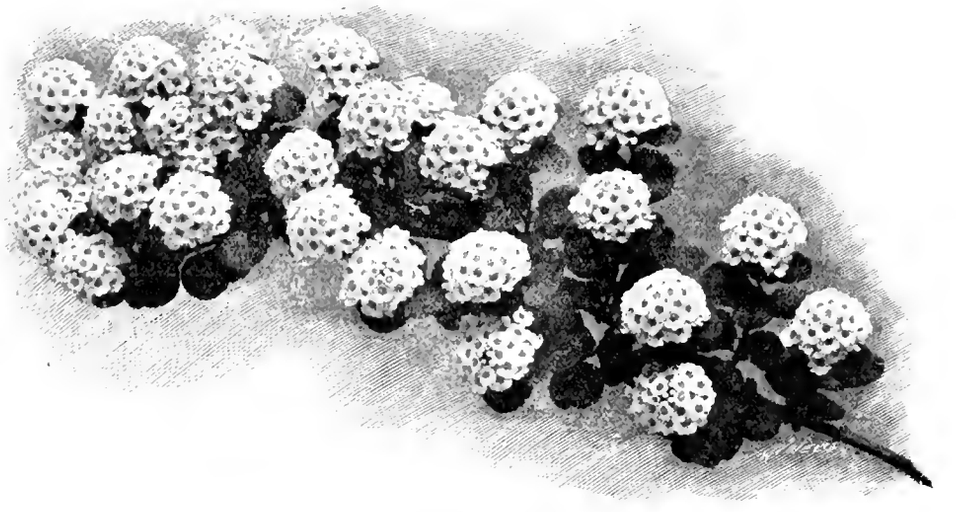

FIG. 180.—SPIRÆA BRACTEATA: FLOWERS WHITE.

(For text see p. 397.)

WINTER LETTUCES.

IN gardens suitably provided with glass accommodation a supply of compact Lettuces may be had throughout the winter and early spring months. Although Lettuces may be considered hardy, they frequently succumb in the winter months, probably not altogether through severe frost, but rather owing to the presence of damp, foggy weather. I have tried wintering in the open many different varieties in varying stages of development, and, although in some seasons they have survived well, the same kinds the following year have proved almost a failure. The great point in obtaining success in the culture of this vegetable under handlights or frames is to provide for a free circulation of air amongst the plants on all favourable occasions. I usually employ handlights for a portion of my crop of spring Lettuces, the remainder being planted on a sunny border. But for winter and very early spring use, the plants are raised in August, and lifted and planted at the foot of a long stretch of glasshouses and close to the brick wall. It is remarkable how well these Lettuces stand the cold of winter, and are useful at a time when salads are much appreciated.

I usually depend upon Cabbage Lettuces for a winter supply, the varieties being Tennis Ball, Tom Thumb, Lee's Hardy Green, and All the Year Round. The small, compact varieties such as Tom Thumb and Tennis Ball can be lifted and planted very closely together, and although they do not attain to a large size, they form compact hearts. If the seed be sown from the beginning to the middle of August rather thinly in shallow drills, and the seedlings be duly thinned and kept watered in dry weather, they will be ready for lifting by the first week in October. Care should be exercised to see that they are taken up with a good ball of soil adhering to the roots; they can then be planted rather closely together at the foot of a south wall. *H. Markham.*

PLANT NOTES.

CLIANTHUS PUNICEUS.

FOR the past fortnight, and at the present time, we have a splendid specimen of this handsome shrub in full bloom. It is situated on a south wall, and was planted in its present quarters from a 6-inch pot about six years ago. Since then it has made good progress, and has reached the top of the wall, which is about 14 feet high, and the plant covers a wall space about 18 feet in breadth. The bright scarlet flowers, of which there is a great profusion, are displayed well against the dark green leathery foliage, making it a conspicuous feature from a distance. The soil here is rather heavy in texture, but it suits the Clianthus. The plant is afforded protection during the winter by means of Spruce branches placed amongst the foliage. Our climate is exceptionally mild, severe frosts being practically unknown, which makes the cultivation of choice shrubs such as the Clianthus a far less difficult matter than it otherwise would be. Cuttings of shoots, inserted about the end of September, in sandy, peaty soil, in a cold frame, have rooted freely, and several raised in this manner have been recently transplanted. Quite close to where the Clianthus is planted a specimen of Solanum crispum is also in full bloom. *R. H. Donaldson, Culzean Castle Gardens, Ayr, N.B.*

EPACRIS LONGIFLORA.

THIS species of Epacris, which is generally seen in gardens and nurseries under the name of miniata, forms a very bright and showy feature in the greenhouse. In most of the garden varieties of Epacris, which have been obtained chiefly from Epacris impressa, the habit of growth is more or less upright, but in the species under notice the shoots are spreading, so that the plant never forms so regular a specimen as

do most of the others. This informal growth is not unpleasing. The flowers are remarkably effective, being considerably longer than those of the other kinds. Their colour is red or scarlet (according to the variety), tipped with white, and hanging as they do from the undersides of the almost horizontally disposed shoots they have an exceedingly pretty effect. One of the best varieties is that known in gardens as Epacris miniata splendens. There is also in cultivation a double-flowered variety of Epacris purpurascens, which, under the name of Eonosmæflora flore-plena, was given a First-Class Certificate by the Royal Horticultural Society in 1876, and was distributed by the late Mr. William Bull, of Chelsea, about half a dozen years later. It was for a time much sought after, but is now little grown, though I have met with it in a few places this season. The individual flowers, resembling tiny rosettes, are borne for a considerable distance along the stout upright shoots. *W.*

The Week's Work.

FRUITS UNDER GLASS.

By T. COOMBER, Gardener to LORD LLANGATTOCK, The Hendre, Monmouthshire.

Early Muscat Grapes.—Examine the borders of those vines upon which the Grapes are just commencing to ripen, and if water is necessary, thoroughly moisten the soil throughout, for if drought in any degree is permitted, the berries will not develop their proper colour. After this has been done, apply a mulch of clean straw on the surface, which will hinder evaporation. The berries of White Muscats, or, indeed, of any other White Grape, will not finish well without exposure in some degree at any rate to direct sunshine. This amount of exposure can be easily secured without having to tie any of the leaves out of their proper position, that is if the vines have been allowed ample space, and have had their laterals properly thinned out. It is essential that no more bunches should be allowed to ripen than bear a proper proportion to the amount of foliage upon the vines, and for this reason I have known bunches of Muscat Grapes to be reduced in number even after the berries have commenced to colour. The atmospheric temperature at night should now be 65° to 70°, allowing a rise by sun heat during the day. There should be sufficient ventilation during the night to cause the atmosphere to circulate, and during the day it should be increased considerably, varying in degree with the external conditions. Careful attention to all these details is necessary, but even then success will not be obtained unless the foliage is kept in a healthy condition and free from red spider.

Late Muscat Grapes.—Encourage the vines to develop the berries, that these latter may become coloured before the days become short. It is most important that the berries should pass through the stoning stage without suffering a shock. Stop the laterals at frequent intervals and thus prevent the growths becoming crowded, or the need arising for cutting away a quantity of fully-expanded leaves. Do not allow the roots to suffer from lack of moisture, and if the vines need manurial assistance let this be given. This will be especially necessary in the case of healthy old vines that have filled their borders with roots, and are now carrying full crops of fruit. Great care, however, is necessary before applying manures to any young vines that have not exhausted the plant food in the borders. If the roots are in outside borders, examine the soil at short intervals, and do not rely upon the moisture afforded by the rains.

Strawberries.—In early districts, especially in cases where plants are grown expressly for affording runners, the work of layering is now being commenced. Sufficient plants should be obtained to allow a surplus to stand in the place of any that may subsequently become "blind." The runners may be layered into pots 3 inches in diameter filled with loam mixed with fine manure obtained from a spent Mushroom bed and a sprinkling of soot. As soon as the young layers have commenced to form roots their extending growths should be removed. The pots should be plunged in the mulching material that was placed on the surface of the bed. Relieve the parent plants of superfluous runners and syringe them and the layers overhead in the evening after hot days. When the pots have become filled with roots detach them from the parent plants and place them in a shady position upon a bed of ashes. When they have recovered from the check caused by the detachment they will be ready for shifting into the pots in which they will fruit. There is no variety equal to Royal Sovereign for pot cultivation.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree, Hertfordshire.

Celery.—Although not generally expected in large quantities before about the middle of August, Celery can be brought to the highest state of perfection even as early as the month of July, and it is often much esteemed at that time. Less time is needed to carry out the blanching at that season than later, and this is best accomplished by using bands of brown paper about 4 inches in width, which will only very slightly impede the growth. The plants may be readily supplied with water at the root, and the blanching will be cleaner and better than if any other material were used. Successional plantings should be kept well supplied with water, and all side growths and bad leaves carefully removed. A diligent search should be made for any trace of Celery fly, and on the first appearance steps should be taken to eradicate the pest; frequent dressings of soot will do much to prevent it causing much damage if dealt with in good time. Green fly is frequently a source of annoyance in the early stages of growth, but if tobacco powder be puffed on to the leaves when they are damp, it will prove an effective cure for this pest. Continue to get out trenches as ground becomes vacant for the latest plantings, and manure all liberally. It is a capital plan to make these plantings between the rows of early and mid-season Peas, which will afford the Celery just sufficient shade to enable the plants to get quickly over their move.

Coleworts.—Few crops are more useful during the early autumn than these small Cabbages, and they seldom fail if proper attention is shown them. The seed should be sown at the present time in a fairly cool and shady place, and again in the first week in July. Immediately the plants are of sufficient size to handle, plant them at one foot apart all ways on well-prepared ground which has had a liberal supply of farmyard manure incorporated. Make the soil very firm, and if clubbing is feared, fill in the holes with fine cinder ashes. The two varieties I especially recommended are Rosette Colewort and Hardy Green. They are both excellent, being of hardy constitution and good quality.

Winter Greens.—These, which include Broccolis, Borecoles, Kales, Savoys, and Brussels Sprouts, should be planted out in their winter quarters as fast as the ground becomes available. It frequently happens that at this season almost every part of the garden is occupied with growing crops, and it will be necessary to plant between such vegetables as Peas, Broad Beans and Potatos, and if attention is paid to removing the various crops in good time, the green crops will be little the worse, and in some cases all the better. An important item to observe is to plant as far as possible on firm ground, and allow a good distance, both between the plants and rows to ensure the growths becoming well ripened.

Late Peas.—The final sowing of these should now be made on a south border. Pay strict attention to those plants just coming through the ground, as to thinning, mulching, watering and staking them.

PUBLIC PARKS AND GARDENS.

By JAMES WHITTON, Superintendent of the Parks and Open Spaces in the City of Glasgow.

The culture of hardy plants (continued).—I would direct attention to another genus of plants as deserving of more attention than it generally receives, viz., the Scillas, which are popularly known as Squills. For ordinary garden purposes much use can be made of the early-flowering Scilla sibirica, and to a lesser degree of S. bifolia. These, however, can only be utilised for minor effects, being fit companions to the Grape Hyacinth (Muscari) and the Glory-of-the-Snow (Chionodoxa). There are also one or two other species, such as the noble S. patula, which must, partly on account of its scarcity, be kept for favoured corners of the garden only. We have, however, in our native S. nutans—the Bluebell or Wood Hyacinth—and its varieties, along with its Spanish congener, S. campanulata, and their white forms all that is necessary so far as colouring in the flowers is concerned. These also best suit our purpose, because they are procurable in quantity at moderate prices. Anything that is rural in character should be carefully preserved in a city park, but it is surprising how few attempts are made in our modern public parks to reproduce simple, natural features. Such a beautiful portion of natural scenery as that exemplified in the grounds about the Queen's Cottage in Kew Gardens is rarely eclipsed in any of our public pleasure grounds; indeed, it is doubtful if Kew, with all its wonderful resources has anything more delightful than this display of the homely Bluebell and other wildings in their season of flowering. We have in three of our Glasgow parks, in which the natural conditions have not been greatly disturbed, displays of this simple flower, and though they offer a temptation to children to gather, they afford the greatest pleasure to town dwellers. Where ordinary rough woodland exists, the common Bluebell should be planted, and, if possible, the bulbs should be obtained from local sources. In parts of the park which pass from the wild to the cultivated portions some of the finer and bolder garden varieties of Bluebells may be utilised. One of the best of these forms I have obtained under two names, viz., Azurea and Cœlestina, but I believe the latter is the correct name. There also exists two white forms, one of which is greatly superior to the other. We have a good purplish form, which was obtained from a private garden, but without a name. This is a very effective plant when cultivated in the Grass, and it is a robust grower. There are several rose-coloured varieties, which, while affording a variation in colouring, are not very effective when seen at a distance, and they should not be mixed with any of the other varieties. The Spanish Squill (S. campanulata) and its variety alba are as effective as the common Bluebell, and they have the advantage of flowering earlier than the native species. An additional feature of the Scillas is their suitability for combination with other plants. More than 30 years ago I had occasion to visit an estate, and, being a stranger to the district, I ventured through a wood, when I reached a shallow glen or gill—to use the local term—wherein I met with a breadth of Bluebells that were growing in conjunction with the Leopard's Bane (Doronicum Pardalianches). Never shall I forget the pleasure experienced by the sight. We have established a similar combination in one of our parks, which, though increasing slowly, promises in time to prove a success. Last year, when on a visit to one of the Midland counties of England, in passing through a copse partly grazed with cattle, I came across a clearing of perhaps half an acre or more in which Bluebells were growing in company with Cowslips. This combination was also charming, and to me unique, as Cowslips are not generally found in numbers in Scotland. There are many other common plants which can be utilised in woodlands; for instance, the Foxglove and the Campanula latifolia. I have also seen the Martagon Lily growing in quantity in a wood, where it produced an effective display. The plants had probably escaped from an adjoining garden. In one of our most recently-acquired parks there is a part known as the "Swiss Meadow." This was formed by the wife of the former owner, and, although the results have fallen short of the lady's ideal, partly on account of unsuitability of the situation and also through the depredations of rabbits, it is nevertheless a source of great interest, and indicates possibilities in this direction. Such schemes are, of course, best suited to the rougher parts and glades in parks where no mowing of the Grass or dressing of the land is practised, and where the ground is undisturbed except in late autumn, when the ground is made tidy. Scillas may be planted on ordinary lawns, provided the mowing of the Grass is deferred until early in July, when much of the foliage has died. We have several lawns thus planted, and, although the sward is kept close cut with the mower, the flowering plants appear to suffer little from their defoliation in the previous year.

THE HARDY FRUIT GARDEN.

By F. JORDAN, Gardener to The DOWAGER LADY NUNBURNHOLME, Warter Priory, Yorkshire.

Strawberries.—It is necessary to protect the berries early from the birds by netting suspended from a framework made of light materials, just strong enough to hold the nets. If the structure is 4 feet high, the fruits can be gathered easily and quickly. A good plan is to run wire netting 4 feet wide around the outside of the Strawberry bed, and to place the fish netting over the beds at this height. See that everything is in position before the berries begin to colour. Afford a layer of litter beneath the plants to keep the fruits clean and, if extra fine berries are required, thin the trusses and support the stalks, so that the berries may be fully exposed to air and sunlight. Should the weather continue dry, afford a thorough soaking of clear water to early varieties planted on warm borders. Later fruiting kinds should be watered with liquid manure, which will induce them to continue growing for a long period. Make a note of those varieties that succeed best, and provide for next year's stock by potting a number of the runners in 3-inch pots as soon as they form. Plant these runners out as soon as they are rooted to furnish an early supply of fruit next year.

Gooseberries and Currants.—In these gardens the bushes of small fruits have been badly attacked by aphis and other insect pests, which have been very destructive amongst other fruit trees. Only by incessant warfare can these pests be kept in check. Shorten back the shoots to five or six leaves, and thoroughly syringe the trees with some approved insecticide. This shortening of the shoots will favour an early maturation of the wood, especially on cordon-trained bushes; in addition, the fruits of this season will be greatly improved thereby. Mulch the roots of old trees that are carrying heavy crops of fruits, and others whose fruits will be required later in the season.

Cherries.—Early Rivers', Mayduke, and other early varieties should receive a final cleansing of their shoots before being netted to exclude the birds, which attack the fruits directly they commence to change colour. The trees require plenty of water during this stage. Later fruiting varieties should also be given copious supplies of water, and the foliage must be kept clear of all pests by a free use of the garden syringe. Fasten the shoots as previously recommended.

General remarks.—Raspberries must have their young canes tied and their roots mulched with rich manure well soaked with water after it is applied. Old plantations of Black Currants will be much benefited by mulchings, also doses of liquid manure. Continue to shorten the breast wood of Pear and Plum trees, tying in any branches that are required for furnishing the trees, and wash the foliage with a stream from the hose or garden engine. Continue to pinch the shoots of bush and pyramid trees as previously recommended.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Major G. L. HOLFORD, C.V.O., C.I.E., Westonbirt, Gloucestershire.

Epidendron prismatocarpum.—It is now the season of flowering of this handsome species. The flowers possess lasting properties in addition to their beauty, and the plant is therefore a very suitable subject for exhibition purposes. When the flowers are over, examine the root system, and if it be found to need new rooting material, this should be given forthwith, using a similar compost to that advised for Cattleyas. The pots, or pans (the latter being the best receptacles) should be first filled two-thirds with material for drainage, as it is essential that water passes readily away from the roots. This plant is best accommodated in a structure having an intermediate temperature, such as a Cattleya house, in which structures they are usually accommodated. During their early stages of growth water must be afforded sparingly, sufficiently only to keep the rooting material moist being necessary. This dry treatment should be continued until new pseudo-bulbs commence to be formed, after which an abundant supply of moisture may be given until the growths are fully developed.

Odontoglossum grande.—After a season of rest, during which time they have been kept on the dry side, these plants are now starting into growth afresh, both above and below ground, and will therefore need repotting or resurfacing with fresh material, as may be necessary. If it is decided that entirely new compost is necessary, employ a mixture of two-fifths Osmunda fibre, two-fifths Polypodium fibre, and one-fifth moss, mixing the whole well together. Use ordinary flower pots, in which are placed plenty of material for drainage, and press the soil moderately firm in the potting, surfacing them with a layer of clean picked Sphagnum-moss. Place the plants in a house having a cool or intermediate temperature, selecting a light, airy position for their staging. A small amount of water at the roots will suffice for some time, and it must be applied with care, so that none of the moisture falls on the young growth, as this generally results in their damping off. When the plants are growing freely they should receive liberal supplies of moisture, and then the syringe may be freely applied whenever the weather conditions will permit, wetting the foliage on all sides.

Odontoglossum citrosmum.—This Orchid is now in flower, the inflorescences being seen to advantage when the plants are suspended in baskets from the roof. They succeed best in an intermediate temperature in a position close up to the roof glass, that must not be too densely shaded. The plants may be grown either in well-drained pots or in baskets, but the latter receptacles are preferable. If any plants require new rooting material, it should be afforded them soon after they pass out of flower, using a similar compost to that advised above and in a like manner. These plants usually shrivel very much after they are disturbed at the roots, therefore the repotting should be done with care, and the plants should be given every attention until they establish themselves again in the new rooting medium. When growing freely, they delight in a liberal treatment and enjoy water in abundance, also sprayings of clear water overhead, which can be afforded on bright days and continued until growth is completed.

PLANTS UNDER GLASS.

By THOMAS LUNT, Gardener to A. STIRLING, Esq., Keir, Perthshire, N.B.

Anthurium Scherzerianum.—Plants passing out of bloom should be given a top-dressing of fresh sphagnum-moss and wood ashes, in which has been distributed a few small portions of broken brick or charcoal. Remove a portion of the old top soil down to the roots, but be careful not to break or otherwise injure any of these organs. Place the new compost close up to the neck of the plant, sloping it towards the outside of the receptacle. Anthuriums are greatly benefited by frequent top-dressings.

Cinerarias.—Seedlings raised from spring-sown seeds should now be pricked out into boxes, which are better than small pots for the purpose. Fill the boxes with a soil of a light texture, and in which has been placed a considerable amount of leaf-mould. Afford the seedlings a space of about 4 or 5 inches apart either way, and then stand the boxes in an unheated frame under a north wall if possible, and on a bed of ashes, which should be previously well damped. Keep the frame closed for a few days, syringing both morning and evening. On warm nights the lights may be removed to allow the dew to settle on the plants, but in the morning the glass should be again put on the frames, and if the sun's rays reach them shading must be afforded. Guard against green fly and thrip, and directly any insect pest appears fumigate with tobacco smoke. If the ashes on the floor of the frame be kept well damped Cinerarias are seldom troubled with insect pest.

Primulas.—Primulas raised from seed this season should now be potted into pots having a diameter of 3½ to 4 inches. A suitable compost is formed of good fibrous loam (one-half), leaf-soil (one-fourth), and fine sand (one-fourth). Use perfectly clean pots, or the soil will cling to the sides when the plants are turned out of the receptacle and some of the roots will become damaged. Place the small plant firmly in the pot and sufficiently low in the soil to prevent it breaking at the neck. Stand the pots in a structure having an intermediate temperature, and well shade the plants from the sun's rays. Stand them near to the glass, for if they are far from the light they become drawn and spindly. As soon as they become established in the fresh soil, remove them to an unheated frame. During the summer months these plants prefer an abundance of light, although not direct sunlight, for which reason it is necessary to afford them a position that is shaded from the sun's rays.

Aralia Veitchii.—Old plants that have become leggy, and therefore unfit for decorative purposes, can, if in robust health, be cut down to within 3 or 4 inches of the rim of the pot, and be made to break into growth afresh. Young shoots will soon form if the plants are placed in a position close to the glass, and of these three of the best should be chosen, and the remaining ones be removed. Of the three selected, one will soon take a lead, and this one should be pinched back so that by the time it breaks again into growth the other two will have developed to the same size. The second year cut each of these three stems down to within an inch of their previous season's growth, and by continuing the treatment of the past year a fine bushy specimen will be formed.

THE FLOWER GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Berkshire

Ripening bulbs.—Most bulbous plants have now finished their flowering, and as the beds are required for other subjects, they should be lifted and carefully ripened. Choose a dry day for the work, and place the bulbs thinly in boxes or on mats, and stand them in some shady spot, where they may be allowed to dry slowly. When they are quite dry, remove the old foliage, the small roots, and any offsets. Label each variety, and place them in a dry, airy house or shed where they can remain until required for planting again next season.

Wallflowers.—Plants raised from seeds sown early in May will now be ready for transplanting. Choose ground that is not too rich, and, in planting, remove the end of the tap root in order to induce the plant to develop a fibrous root system, for this conduces to a dwarf, compact growth above ground. Seeds of Wallflowers may still be sown with success.

Polyanthus seedlings will now be large enough for transplanting. Choose a site on a shady border, such as provided by one under a north wall. Plant them at a sufficient space apart to enable the hoe to be plied between the rows. Old plants may now be divided at this time; these divided portions will form good plants that will furnish an abundance of flowers next spring. The Polyanthus prefers a gritty soil, having an open texture.

Hollyhocks.—Pluck off any of the leaves that are affected with the Puccinia disease so prevalent among these plants, and encourage a vigorous growth by copious waterings and liberal applications of liquid manure. Use the Dutch hoe freely in dry weather in order to retain the moisture in the soil and to destroy weeds.

Gladiolus.—Plants growing in light soil need frequent applications of moisture, and, as a mulching to prevent undue evaporation, spread evenly over the surface of the roots a layer about 2 inches deep of horse-droppings. If they are planted in beds by themselves see that all weeds are destroyed by the hoe. Stake the plants early in order that the flowering spikes may be secured before they become damaged by wind. Arrange the stakes so that the top of the stake is just below the lowest flower, otherwise the blooms will become rubbed and bruised against the stake.

Perennial Asters will also need staking. In the case of varieties of medium height, the best stakes are formed of twigs, as the effect is more natural than is the case when stiff, formal stakes are used.

Hardy Ferns, including Osmundas, Polystichums, Scolopendriums, &c., need copious supplies of water at this season, for even in very rainy weather the dense canopy formed by the fronds prevents the moisture from reaching the roots of the plants. It will be good practice to sprinkle these plants overhead both morning and evening during hot weather.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden W.C.

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations. *The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.*

Newspapers. *Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, JUNE 20—German Gard. Soc. meet.

TUESDAY, JUNE 23—
Roy. Hort. Soc. Coms. meet. Oxford Fl. Sh. Hort. Club.

WEDNESDAY, JUNE 24 -
Richmond Fl. Sh. Hort. Sh. at the Franco-British Exhibition, Shepherd's Bush (3 days).

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—61·2°.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, June 17* (6 P.M.): Max. 68°; Min. 56°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, June 18* (0 A.M.): Bar. 29·9; Temp. 65°; Weather Bright sunshine.

PROVINCES.—*Wednesday, June 17* (6 P.M.): Max. 61° Guildford; Min 49° Durham.

SALES FOR THE ENSUING WEEK.

FRIDAY—
200 specimen dwarf and rare Japanese Trees and flowering plants, Vases, &c., Palm seeds, Orchids in flower and bud, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 1.

Colours in Plants.

Few phenomena of nature are more striking than the brilliant and varied colours of the flowers, or the splendour of the tints in an autumnal woodland. But although the matter has formed the object of innumerable researches, much still remains to be done before we shall be in a position to give anything like a complete explanation of the nature of the colouration in plants. Nevertheless a good many facts have been gleaned, and they are not without interest for those who are not merely satisfied with things as they are, but want to know something about their causes and properties.

There are very many classes of colours, but for the sake of convenience it is easy to group them into two classes.

In the one of these, the pigment is dissolved in the cell sap, and so forms a coloured liquid which is contained in the spaces of the protoplasm of each of the cells, whilst in the other class the colour is associated with small but definite solid structures embedded in the cell. Very many of the blue and red colours are of the former nature, and it often happens that it is only those cells which form the superficial skin of the organ leaf or petal which contains the dissolved pigment. The reddish-purple of the Copper Beech and the various tints on a Tulip belong to this class. It seems almost impossible, when one sees a feathered or flamed "broken" Tulip, to realise that the pattern is only skin-deep, but anyone may easily enough convince himself that it is so, by simply peeling off the epidermis from such a flower.

Many of the blue or red flowers possess pigments that can be changed the one into the other by acids or alkalis respectively, and it often enough happens that the two colours are present on the same plant, as, for example, in the coloured bracts of Salvia Horminum. The blue (or violet) tint means the presence of alkaline, whilst the red colour betrays an acid, cell sap. The change from one to the other can often be brought about by holding the coloured organ over some volatile alkali, for example, ammonia, or an acid such as hydrochloric acid.

Some plants are easily induced to assume red tints in their otherwise green leaves, and this is often connected with their nutrition. The Dock tribe furnish well-known examples of plants which often exhibit splashes of red on their foliage, and this can, in suitable instances, be produced by the simple device of severing some of the "veins" of the leaf, and so interfering with the passage of substances away from it into the stems. Temperature is another indirect agency in the production of colour: thus a low temperature and bright illumination tend towards the production of pigments, and perhaps helps to explain the astonishing brightness of the Alpine flowers.

Other causes also intervene to modify normal colour. Iron is recognised as essential to the formation of green colours in leaves, and there is also evidence to show that it is at any rate one of the causes which may promote a bluish colour in Hydrangea. Unfortunately we do not as yet know how the effect is produced in the latter case; we do not understand the chemistry of the process, nor why a blue colour should be produced in this plant, whilst in other flowers different tints seem to be related to the presence of the same element. Analogous examples will occur to everyone, such as the vivid brightness of the blue and yellow flowers of plants growing on limestone as compared with the same species on other soils to select merely one striking and familiar example.

The second class of colours is not due to the presence of coloured sap, but to the existence, within the cell, of coloured corpuscles. The best known of these are, of course, the chlorophyll corpuscles, to which leaves owe their green colour. In leaves these corpuscles are for the most part absent from the epidermis, and are especially abundant in the cell layers just underneath it, on the surface directly exposed to the light. As is generally known, they have a most important function to discharge, namely, that of enabling the plant to build up food, under the influence of appropriate light, from very simple raw materials. It is not too much to say that the whole of the animal kingdom is ultimately dependent on the existence and functions of the chlorophyll corpuscles, for they build up, directly or indirectly, practically the whole of the food on which animal life subsists.

The chlorophyll granules are moveable within each of the leaf-cells, and they take up different positions which are related to the intensity of the light. The relatively pale green of the leaves on a bright summer day is due to this cause. The corpuscles are so arranged as to shelter each other. But by shading a part of the leaf, with a bit of darkened paper for example, the deeper tint will be seen to have returned if the paper be removed after a little time, and this change is due to the corpuscles having again spread themselves out in the cells thus temporarily shaded.

Now the chlorophyll corpuscle is by no means a simple body. It consists of a dense framework coloured by an oily green substance. The latter can readily be extracted from the solid matrix by soaking the leaves in alcohol, and the difficulties of investigating it then begin. Without going into details, we may say that there are at least two colouring matters present, a blue-green, and a yellow one, the latter closely resembling, and perhaps identical with, that which gives Carrots their orange colour.

Everyone knows that plants grown in the dark are not green, but are of a sickly yellow or white colour. Nevertheless plants grown under these conditions possess chlorophyll corpuscles, but the colouring matter is not developed. It needs only a short exposure to light to cause them to turn green, just as an exposed photographic negative only needs the developer to bring out the image which was latent in the film. In each case the transformation from the invisible antecedent to the finished product is associated with chemical change, and can only take place under suitable conditions.

Now the green and yellow (or red) constituents in the chlorophyll corpuscle may change their relative proportions a good deal, according to circumstances, and further colour changes may also go on accompanied by the formation of even crystalline substances in the corpuscle which may so distort it as to render it almost unrecognisable. Most yellow colours are thus produced, and also some red ones. Thus when a green Trollius bud unfolds to a yellow flower, the colour is due to changes such as we have indicated, and the same occurs in the reddening of Rose hips. Autumn leaves also owe their brilliant tints largely to changes that occur within the chlorophyll corpuscles, depending on the disappearance of the green and the increase of yellow or orange colour-bodies. Sometimes the chlorophyll corpuscle simply loses all its colour, and then the organ assumes a white appearance such as is seen when the Snowberry (Symphoricarpus racemosus) ripens its fruits.

A puzzling case is observed in many plants with variegated leaves. The causes of the local loss of colour are not well understood, and they are complicated by the fact that in some cases the variegation of a scion will affect the stock on which it may have been grafted. Such an example illustrates the truth of the statement we have already made, that the causes that are responsible for the colour changes in plants are often very complex, and at present lie for the most part outside our knowledge. But although this is the case, the whole subject is one of fascinating interest, and it will long continue to repay scientific investigation.

OUR SUPPLEMENTARY ILLUSTRATION affords a view of some flower-beds at Wynyard Park, near Stockton-on-Tees, the residence of the Marquis of LONDONDERRY, K.G. The scroll-shaped beds, are outlined by an edging of Box, the paths between being surfaced with spar. Last season, when our photograph was taken, the small circular beds in the centre were each planted with a specimen of White Queen single Dahlia, and edged with Perilla; the S-shaped beds contained dwarf plants of Ageratum and Ivy-leaved Pelargonium Mme. Crousse alternately. The Pelargonium was mainly pegged to the ground, but at intervals a plant was trained to a stake 2 feet high to furnish relief. The outside portions, which at intervals are pointed inwards, were planted as follow: the points and portions opposite the end of the Ageratum beds had a plant of the dwarf Dahlia "White Bedder," and this was surrounded by plants of Ivy-leaved Pelargonium Mme. Crousse. The portions opposite the inner beds of these latter plants was furnished with blue Lobelia, the variety being Mrs. Clibran. The arrangement is altered annually, but the effect is always good. Most of the beds seen on the lawn are filled with tuberous-rooting Begonias in distinct colours of crimson, pink, white and yellow. The colours of the flowers in the borders are planted so as to produce a pleasing effect from a distance; for instance, crimson shading up to white or the reverse, white shading up to crimson. The flowers in the borders are planted so as to produce a good colour effect. This season the east end border is planted with flowers having shades of blue, the west end with white and yellow. A large ribbon border which runs parallel with the scroll is bedded as follows, commencing at the front:—Two lines each of Alyssum minimum, Lobelia Mrs. Clibran, Ivy-leaved Pelargonium Mme. Crousse, Pelargonium Henri Jacoby, P. Paul Crampel, Perilla macrophylla compacta, Dahlia White Bedder, and D. Sydney Hollings. Mr. H. E. GRIBBLE, the able gardener at Wynyard Park, makes the flower gardening one of the most attractive features, over 7,000 tender plants being used for this purpose.

THE FLOWERS OF SPENSER.—The science and art of gardening are essentially practical questions, and in the economic culture of plants there is not always room for sentiment or poetry. But the study of flowers, if regarded as something separate to their cultivation, has led many to appreciate the sentiment connected with them, and to rejoice that their interest and beauty have given inspiration to most of the greatest writers and poets in the world's history. Even the more practical among us have moments when the poetry or sentiment of the flowers we tend from day to day charm us, and we turn to SHAKESPEARE or our favourite poet to see what he has said of them. The Rev. Canon ELLACOMBE, himself a devoted gardener, has studied the poetic qualities of flowers whilst cultivating his well-stocked garden at Bitton, and has already published a small volume under the title of *Plant Lore and Garden Craft of Shakespeare*. His contributions upon the "Flowers of Spenser," which commence in our present issue, will appeal to all those who are interested in the literature of plants.

ROYAL HORTICULTURAL SOCIETY. — The next exhibition of flowers and fruit will be held at Vincent Square, Westminster, on Tuesday, June 23. At 3 o'clock a lecture on the "Absorption of Rain and Dew by the Green Parts of Plants" will be given by Rev. Professor G. HENSLOW, V.M.H.

JUBILEE OF THE YORKSHIRE GALA.—To commemorate the jubilee of the Grand Yorkshire Gala, which has been held during the present week, the committee has issued a pamphlet containing interesting information respecting the shows that have been held since 1858 until the present time. It appears that the gala was inaugurated on November 30, 1858, at the Old George Hotel, in the Pavement, York, the first meeting of the subscribers to the Guarantee Fund being held under the chairmanship of the late Mr. WILLIAM HOLLIDAY. There were nine other gentlemen present, and each member guaranteed a sum of £20. The guarantee was subsequently shared by 30 members forming a standing committee, and it was decided that the profit from the concert and first day's exhibition, after deducting all expenses, should be paid to York charities. It is interesting to note that the first exhibition held on June 14 and 15, 1859, was attended by 17,920 people, and the gate money amounted to £1,026 17s. 6d. The charities benefited to the amount of £120. In looking through the records for each year, we note that in 1861 a regrettable incident was the death of a boy accidentally killed by fireworks. In 1896 the Society was honoured by the attendance at the gala of a deputation from the Royal Horticultural Society. The gala of 1897 being in the 60th year of the reign of her late Majesty QUEEN VICTORIA, an extra grant of £50 was voted for a class for groups of Orchids, and £29 contributed to the Day of Thanksgiving Fund. This proved one of the most disastrous galas the Society has held. On the morning of the first day there was such a gale that the marquees containing the exhibits, and covering an area of about 3 acres of ground, were blown down, the poles snapped in twain, and the canvas in many instances was torn to ribbons. Many of the exhibits were removed, but the gala, as far as possible, proceeded, the admission on the first day being reduced to half-price, and the loss on the gala altogether amounted to £500. In 1906 the tents were for the first time lighted by electricity. During the 49 years of its institution, no fewer than 1,844,817 persons have paid for admission to the grounds, exclusive of subscribers and other ticket holders, the record attendance for three days being in 1899, when the numbers reached 57,383. Nearly £2,600 have been disbursed in prizes in the floral department. The Society has contributed the sum of £2,682 5s. to charitable objects, including a sum of £62 10s. to the "Gardeners' Orphan Fund, &c." The garden charities do not appear to have benefited to an undue extent. The official souvenir contains many photographs of past and present presidents and officials, and also scenes from some of the galas.

MONS. EDOUARD ANDRÉ.—In a paragraph on page 385 of our last issue, MONS. EDOUARD ANDRÉ was inadvertently referred to as a nurseryman. MONS. ANDRÉ, who has been editor of *Revue Horticole* for many years, is a landscape gardener of great fame throughout France, but he has never been what is termed in this country a nurseryman. We regret to know that our colleague is so seriously indisposed that he is at present unable to continue the work in which he distinguished himself so brilliantly.

A FIXTURE LIST. — Messrs. AUSTIN & MCASLAN, nurserymen, 89, Mitchell Street, Glasgow, have compiled a list of fixtures of flower shows and other horticultural functions to be held principally in Scotland. The towns are arranged in alphabetical order, which renders it an easy matter to at once determine the date of a particular flower show. The chief London, provincial, and Irish fixtures are included at the end of the booklet.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—We are asked to again remind our readers of the 69th Anniversary Festival Dinner in aid of the funds of the Gardeners' Royal Benevolent Institution, which will take place on Wednesday next, June 24, at the Hôtel Metropole, under the presidency of the Lord ALDENHAM, who will be supported by an influential and distinguished company. Donations to be placed on the Chairman's List are earnestly solicited, and may be sent direct to the Lord ALDENHAM, to HARRY J. VEITCH, Esq., the Treasurer, Chelsea, S.W., or to the Secretary, Mr. GEORGE J. INGRAM, at the offices, 175, Victoria Street, Westminster.

ROYAL HORTICULTURAL SOCIETY OF IRELAND. — Mr. EDWARD KNOWLDEN has been appointed secretary of this Society. The address is 5, Molesworth Street, Dublin.

RATS AND MICE IN THE GARDEN.—These little creatures are a pest to the gardener, who often bewails the loss of his seeds and fruits owing to their depredations. Not long since we visited a garden, in which the culture of Sweet Cherries had been abandoned because these rodents were so troublesome in eating the ripe fruits. Poisoning is the surest method of destroying them, but poison cannot always be employed for fear of injury to domestic animals. The E. SCALES MANUFACTURING CO., of Station Road, Sidcup, London, S.E., send us particulars of a new patent trap. It is called the "Go-bang," and kills the creature by means of a falling bar, which, when released, is sent down by a powerful spring. There is a larger size for the trapping of rats. The trap is made either in wood or in galvanised iron.

AMERICAN GOOSEBERRIES. — A large proportion of the Gooseberries cultivated in the United States and Canada (writes Mr. J. G. BAKER), are descended from Ribes oxyacanthoides of LINNÆUS, and not from the nearly allied European and Asiatic Ribes Grossularia. Ribes oxyacanthoides differs from Ribes Grossularia in having a less erect habit, more spreading branches, usually simple spines, thinner, less glossy leaves, often hairy beneath, and smaller berries, with a thinner skin and rather different flavour. Ribes oxyacanthoides is widely distributed as a wild plant in the North American continent, extending from Newfoundland and the Northern American States, northward through Canada to Hudson's Bay, and westward to New Mexico and California, where it reaches a height of 6,000 to 9,000 feet on the Sierra Nevada. It appears to bear the hot summers of the United States better than R. Grossularia, which is also widely cultivated in America under the name of the English Gooseberry. R. oxyacanthoides seems to vary greatly in the armature of its stems, the hairiness of its leaf-stalks, and the lower surface of its leaves, and the colour of its flowers and fruit. A less prickly, glabrous form is figured in the *Botanical Magazine*, tab. 6892. A form with hairy leaves is R. hirtellum of MICHAUX, and a variety armed with copious setæ between the true prickles is R. setosum of LINDLEY, tab. 1237. Although it has been known in England from the days of DILLENIUS, who figured it in *Hortus Elthamensis* in 1732, it does not seem to have been cultivated in Britain, except occasionally as a botanical curiosity; but it might be worth while for some of our enterprising fruit-growers who are in search of a novelty to try it, for it reaches so far north that it must be adapted to our English climate. A commonly-cultivated American form is known as the "Downing Gooseberry." Another species, Ribes Cynosbati, is also occasionally cultivated in the United States.

ASPARAGUS PLUMOSUS, so much used for decorative purposes, is cultivated out of doors for market purposes near Naples. According to a writer in *Revue Horticole*, Sig. M. TRAVERSO has succeeded by a cheap and ingenious device in overcoming the difficulties due to excessive dry heat and the dangerous winds that occur in that part of Italy. His plantation, which is situated in the district known as the Phlegræan Fields, is surrounded with close lattice work, and is roofed over with the same material at about 7 feet from the ground. The results are said to be excellent, and the plants grow freely and give very little trouble.

QUALITY OF SEEDS.—The influence of the character of the seed on the crop that will be produced from it is well known as a general fact. But it is probable that more detailed attention than is very often given to the matter would well repay the trouble entailed. It is becoming better understood than formerly that the very early life of a plant has an overwhelmingly important influence on its subsequent growth. Thus it is a matter of common experience that some plants rapidly improve, if grown even for a few generations under specially favourable conditions. This is certainly to be attributed, in great part at any rate, to the cumulatively favourable start in early life enjoyed by the plants themselves. The environment thus continues to influence the development through several generations, and in a cumulative fashion. This circumstance has given rise to a certain amount of confusion as to the existence of inheritance of acquired characters. Probably what has really occurred is that the accumulated wealth of one generation serves to endow the seeds of the next with more capital in the form of food, and this will produce its effect during the youthful and most important period of growth in the seedling. This view is supported by the ease with which such improved races degenerate when favourable conditions are relaxed. Such considerations, which are borne out by facts, serve to emphasise the desirability of more thoroughly studying the relations that exist between the various properties of the seed and the quality of the progeny that will arise from them. The matter is not new, but it is still worth a very careful scientific investigation, and the results are certain to be of practical value.

AN AMBITIOUS DINNER-TABLE DECORATION.—A writer in the *Florists' Exchange* (American) recently described a Japanese dinner decoration carried out by a gentleman who has spent a great many years in Japan. The occasion, he states, was a birthday party, the table being set for 12 covers. The decorator stepped out of a touring car with a collection of mysterious-looking boxes and bundles, and immediately took possession of the dinner table The first package to be undone contained several sheets of dyed green moss; the next a shallow oval tin basin about 2 feet in diameter and 2 inches deep; this was placed in the centre of the table and banked around with crumpled papers taken off the packages. Several other bundles were placed here and there on the table, which, covered with the sheet-moss, formed miniature mountains and valleys. Other packages revealed Ferns, pagodas, huts, bridges, boats and a host of other things which go to make a Japanese landscape. The tank in the centre formed the lake; this was covered on the bottom with white gravel; a rugged piece of tuffa rock made a perfect island, which was surmounted by a pagoda, with an industrious angler sitting at the water's edge. Diminutive goldfish and a very young alligator seemed quite at home in the water. Paths were formed by sprinkling fine gravel over the green moss, a stone lantern being placed here and there along the walk. Japanese flowering Almonds (Prunus biloba), in full flower and growing, were placed on the ends of the table and mounded over with moss; wires were stretched from one to the other across the tables on which were hung tiny lanterns; these were fitted with two candle-power electric lights; this was the only lighting used and the effect was extremely pretty. Small white mice were used for favours for the ladies; these were imprisoned in small gilded cages. Small turtles were given to the gentlemen, and goldfish were used in the finger bowls.

THE RAILWAY TO JERUSALEM, AND ORANGE CULTIVATION.—Reporting on the trade of Palestine for the past year (Annual Series, No. 3,974), Mr. Consul BLECH refers to the projected railway from Haiffa to Jerusalem. He says this undertaking has been decided upon, and that it is to be completed within two years. A new means of access to Jerusalem will thus be afforded, which should prove a great boon, as the dangerous and frequently impossible landing at Jaffa will be avoided. But it will be necessary to build a port at Haiffa, which, though possessing natural advantages, is at present but little better than Jaffa. The construction of the projected railway, which will probably be some 100 to 120 miles in length, will no doubt injure Jaffa by diverting from it a portion of the pilgrim and passenger traffic, and it is feared that the Government will do all in its power to favour Haiffa at the cost of Jaffa, in the interests of the Hejaz State Railway. But it is unlikely that Jaffa will ever lose its position as the port for Jerusalem and the neighbouring region, while the growing export trade in Oranges will maintain its importance as long as the fruit finds a ready sale in the United Kingdom. The future prosperity of the plain of Sharon seems in great measure to depend on the Orange export. In 1897, only 290,000 cases were exported; the total has now risen to 630,000 cases, and it is confidently expected that within a very few years the output will reach 1,000,000 cases. The case contains from 100 to 150 Oranges, according to the size of the fruit; the weight is about 80 lbs., and the freight to Liverpool about 1s. 3d. per case. It is usual for the owners of Orange gardens to sell the produce long before it is ripe to speculators, who thus take off their hands all further trouble and responsibility. The price so obtained by the grower is about 2s. 4½d. per case; the cost of packing is estimated at 1s. 2d. Anything obtained over 4s. 9½d. per case at Liverpool represents the speculator's profit, on whom, however, falls all loss incurred through hailstorms, such as have lately prevailed, as well as all other risks, until the fruit is shipped. It would seem from these figures that the grower gets a little less than a farthing apiece for Oranges sold in London shops at 2d. *Journal of the Royal Society of Arts.*

THE RUNNING TO SEED OF THE CABBAGE LETTUCE.—During the hot summer months the gardener finds that many of the Cabbage Lettuces are running to seed. Although this mishap cannot be wholly prevented, everyone may, by following the practice here given, bring about an essential improvement in his stock. The chief condition is to cultivate only such varieties as are found to succeed in the district. When the plants begin to form hearts, the finest of these should be marked throughout the bed, and as soon as these marked plants begin to shoot they should be pulled up for use, and this practice is to be persisted in till only so many plants remain in the bed as will suffice for affording a crop of seed. By this process of selection, carried on for some years, plants may be raised which will fully resist the effects of hot weather. *B. Ebensberger* in *Moller's Deutsche Gartner-Zeitung.*

NURSERY NOTES.

VIOLAS AT MESSRS. DOBBIE'S.

ON Saturday, June 13, a visit was paid to Messrs. Dobbie & Co.'s Seed Farm at Mark's Tey, to inspect a collection of Violas which was planted out in an open field, with a view to testing their hardiness and relative values. There were 76 sorts, which had been procured from various sources; they were planted last October, and arranged in colours. All had succeeded fairly well, and though quite unprotected, had stood the weather well. Some were in flower quite early in the year, and they have kept up a succession ever since, appearing likely to continue to do so until the end of the summer. It was interesting to note that some of the old varieties are still among the best for bedding purposes; whilst some of those with the most perfect-shaped flowers, though the specialist or exhibitor may value them, cannot be recommended for market-growers or for general bedding.

Taking the varieties in order, there were 19 white sorts. As a pure white, Snowflake was selected as the best variety. Alexandra, with a slight ray in the centre, came next, but was a little taller. Marchioness, though not quite so good in form of flowers, was very free, and one which should be useful for supplying the market. Pencaitland, a very free-flowering sort, with a yellow marking on lower petals, Countess of Hopetoun, and Duchess of York, were recognised as good varieties. Sylvia had good qualities, but should have been included with the creamy shades. Mrs. H. Pearce had large, well-formed flowers, but may be regarded more as an exhibition plant than as a bedder.

In the creamy shades there were only two varieties included, and of these Cream King was considered to be far better than Devonshire Cream.

In primrose varieties there were six, and of these Primrose Dame was regarded as the best, but Sulphurea was also good. Ardwell Gem is well known, and though the flowers were not of such good form, it is one of the best bedders. Maggie Clunas had large flowers; Iliffe should have been included with the creams.

Of yellow sorts there were eleven, and all had some points of merit. Redbrass Yellow was selected as the best rayless (or clear yellow) variety, and Walter Welsh as the best with a slightly rayed centre. Bullion was reported to be one of the earliest, and was very showy. Kingcup was good, but of a paler shade. Royal Sovereign has a deep colour, but as seen was not so good as the others in habit of growth.

In lavender shades it was difficult to decide which was the best. In the first place there was some range in the shades of colour, but of the six varieties grown, Florizel was decidedly the best in habit for bedding. Kitty Bell was, perhaps, of a better tint, and was reported to be one of the earliest to flower. Belfast Gem was good, this had a light centre to the flowers.

Of light blues there were seven, and Maggie Mott was selected as the best. Mauve Queen was also good. Blue Duchess was likewise selected as a useful variety. Favourite is very dwarf and compact, and Lilacina is one of the best varieties for bedding.

In dark blue varieties Councillor Waters was considered the best, but Jubilee might be regarded as identical with it. True Blue was of a very compact habit. Admiral of the Blues was of a rich, deep colour, but had grown rather tall. Archibald Grant was another good variety with the same fault. Ophelia met with appreciation.

Royal Scott was very dwarf. Chas. Jordan had better-formed flowers. All of the 11 varieties had some merit. Lady Warwick was planted rather later, and had not had a fair chance; the flowers were good, but the habit could not be properly judged.

In those varieties which were termed Fancies (or unclassed), of which there were 12, Glencoe, a deep bronze shading off to old gold, was one of the favourites; it had grown rather tall, but it is a colour that would sell well in the market. Dr. Macfarlane, a deep, shaded variety; Blue Cloud, free and early; Ada Anderson, white with a blush lavender shading; William Neil, a rosy-shaded variety, dwarf; Mrs. Chichester, white shading off to reddish mauve; and Crimson Bedder were approved. An unnamed seedling of a bronzy-red shade was attractive.

NOTES FROM A "FRENCH" GARDEN.

At the present time all our attention is directed to the culture of Melons. The general conditions underlying this culture are as follow: (1) Plenty of heat to cause the seeds to germinate; (2) potting off the young plants before they become weakly from inattention; (3) planting them out as soon as they are ready for cultivation in specially prepared beds; (4) a proper supply of water and ventilation, increasing with the growth of the plant and applied always with discretion; (5) careful selection of the fruits allowed to ripen on each plant.

If attention is given to each of these items and an intelligent interest taken in carrying out all the details, success may be assured.

FIG. 181.—ZEPHYRANTHES AUREA: FLOWERS YELLOW.
(Award of Merit R.H.S. meeting June 9.)

SWEET PEAS AND AQUILEGIAS.

All the new varieties of Sweet Peas are on trial; most of them had some flowers open, but it was too early to judge of their relative merits. A large breadth of the long-spurred varieties of Aquilegias which were being grown for seed were of the best type; almost every colour that could be imagined was seen in a large bed of mixed varieties.

Most of the large farm is devoted to growing vegetables and flowers for seed, and a little later there will be a great show of colour. Some herbaceous plants are grown, also bulbs, and a large bed of Spanish Irises included some very fine varieties of this section of Iris.

During the past week we have pinched the growths upon plants set out during the first part of May. Owing to genial weather the female flowers which appeared early in the growth set freely, and the fruits commenced to swell. It may cause surprise, therefore, when I say that we cut off all these little fruits, as the plants were not sufficiently established to properly develop them. Had we left these fruits to ripen, this crop would have immediately followed the first batch, and it would have been inferior in quality. Watering is done every morning between the hours of 6 and 9, the plants being divided into two groups, which are watered on alternate days.

Air is admitted in varying degree from 7.30 a.m. until 6 p.m., unless the presence of wind or rain obliges us to close the lights earlier.

We are still planting Melons, and it is probable that owing to pressure of work we shall not finish the planting before June 20.

We are fast clearing away the Carrot crops, and there are only a few beds left. The crops are rather later than usual, owing to our having cultivated a rather later variety than was the case last year. I strongly advise the cultivation of "Early Parisian" Carrot, even if the saleable value is not equal to that of a bigger rooted variety, because the Cauliflowers have needed extra room these last two weeks, and what was gained in getting larger Carrots has been lost in the hindrance they caused to the Cauliflowers.

We have already cut some Cauliflowers. The early batch of 2,400 plants keeps one man busy all day in watering them. Every morning they are examined in order that the developing flower on particular plants may be covered with leaves taken from the base of the plant. By this attention we obtain Cauliflowers as white as milk, and, therefore, they are the more appreciated in the market.

The Endives raised from seeds sown at the beginning of March and planted outside are ready to be tied for the purpose of blanching. This work is always done after a thorough watering has been given, and when the leaves have again become dry. The Endives intended to follow the Cauliflowers will be ready as soon as they are required for planting out. We are now sowing a batch of Endive of the variety known as Ruffec for autumn supply.

We are clearing our last batch of Cos Lettuces; these always sell for a good price, and at present realise 25 per cent. more than Lettuces grown in the neighbourhood from plants raised from seeds by us. The reason for this is that other growers have cut their plants too early, and have never given them any water.

All the Celery plants have been pricked off into beds previous to the final planting. We shall not grow very many, as being gross feeders they take too much goodness out of the manure on which they are planted. This manure being required for use as soil in the following year, we cannot prejudice future crops for the sake of the Celery.

The dry weather experienced during the past few days has demonstrated the value of a well-considered system of irrigation. No money should be spared in making provision at the outset for a proper water supply, as this lies at the root of success in a "French" garden. This will be the better understood when it is remembered that all the crops are of a sappy nature, and they are cultivated in very porous soil, which, if allowed to get thoroughly dry once, can hardly be properly soaked through, the crops therefore linger on the soil rather than develop, and thus prevent other crops from being planted, and this naturally causes loss to the grower. *Paul Aquatias, Mayland, Essex, June 11.*

ZEPHYRANTHES AUREA.

THE illustration at fig. 181 represents this interesting and pretty Peruvian bulbous plant, which was shown by Sir Trevor Lawrence, Bart., K.C.V.O. (gr. Mr. W. Bain), at the last meeting of the Royal Horticultural Society, where it received an Award of Merit. It is one of the brightest yellow-flowered, bulbous plants of compact growth which has been yet introduced, and it is singular that the species, which was known many years ago in gardens as Pyrolirion aureum, should now be regarded practically as a new plant in cultivation, and that its recent introduction should have been from South Africa, from whence Sir Trevor Lawrence's son sent it, and where it must have been an introduced species.

BULBOPHYLLUM ORTHOGLOSSUM.

THE remarkable species illustrated at fig. 182 was shown by Messrs. Sander & Sons, St. Albans, in their group at the Royal Horticultural Society's meeting on June 9. The species was first introduced by Messrs. Sander & Sons through their collector, Micholitz, and described by Dr. Kranzlin in the *Gardeners' Chronicle*, March 14, 1896, p. 326, from a specimen sent by Herr Wendland, of Herrenhausen, near Hanover. The species in general appearance is nearest to B. mandibulare. Its flowers are greenish tinged and striped with red-brown, and the more deep red-tinted labellum is peculiar in the genus. Of it the author states: "The lip of this new species is perhaps unique in the genus. At first it is really three-lobed, the side lobes being comparatively small, bent forward, toothed at the margin, and covered with little warts on the inside; the mid-lobe has a cushion-shaped, thick base, and a tongue-shaped, fleshy, acute, straight apex. It is a warm-house species."

KEW NOTES.

KEW IN EARLY JUNE.

IN the heat of the early days of June Kew Gardens were delightful. The Lilacs were nearly over, but the Azaleas were in their glory, with their brilliant hues of scarlet, orange, yellow and sulphur. Numbers of Rhododendrons were in flower, but, apparently, many had failed to bloom, probably owing to last year's gloomy and damp summer. Magnolia stellata was past its best, but M. Soulangeana, M. obovata, M. tripetala, the pale yellow M. Fraseri, M. acuminata cordata, with small greenish-white flowers, and the clear yellow M. cordata were in bloom. The Rose dell was not as yet at its best, the only flowers out being Rosa altaica, R. spinosissima lutea, Carmine Pillar, the Dawson Rose, and R. spinosissima hispida, pale yellow. A mass of Viburnum plicatum made a fine show, and a bed of Crambe orientalis had a handsome effect, while Petteria ramentacea, with clusters of yellow, pea-shaped blossoms, was pretty. The beds of Flag Irises made a welcome display of colour, and I. sibirica, growing in the water, was very ornamental. The rock garden, compared with last year, was rather disappointing. Of the many rare Gentians then to be seen, none was in evidence, and the handsome Meconopsis integrifolia and M. punicea were conspicuous by their absence. The only Meconopsis present was the small blue M. racemosus. The Ramondias, in the perpendicular rock walls, were in full flower, interspersed with sheets of the pretty little Arenaria balearica in full bloom, creeping over the stones. Below were Primulas japonica, Chamælirion carolinianum, with white flower-spikes 9 inches high, and Orchis latifolia. Rodgersia podophylla was blooming finely, and R. æsculifolia was coming into flower. Of the Saxifragas, S. lantoscana, S. cochlearis and S. c. minor, S. lingulata, S. Portæ, S. Hostii, S. Cotyledon, S. Macnabiana, S. Aizoon, S. cuneifolia, and S. punctata were blossoming, and among the plants in flower were Dianthus acaulis (pink), D. alpinus (rose), Anemone baldensis (with yellowish-white flowers), A. sylvestris, Geranium cinereum (pale pink), and G. c. album, the purple-bis tectorum and I. grammea, Podophyllum versipelle, from China, with large, deeply-cut leaves 18 inches across and clusters of maroon-brown flowers, Helianthemum umbellatum, a small shrub with white blossoms, Wahlenbergia tenuifolia (pale lavender), Veronica pectinata rosea, Dicentra eximia and D. formosa, Potentilla alba and the yellow P. nevadensis, the orange Erigeron auranticum, and E. salsuginosus, with lavender-pink flowers 2 inches across, the orange Primula Cockburniana, Myanthemum Convallaria, a mass of white bloom, Phlox divaricata and P. reptans, the dwarf Pentstemon pubescens, with lavender-pink flowers, Dodecatheon Meadia, Valeriana tripteris, with heads of tiny pinkish-white blossoms 6 inches in height; the rose-coloured Hedysarum obscurum, the dwarf and pretty Vicia pyrenaica, bearing carmine, pea-like flowers, Viola gracilis, Hippocrepis comosa, Verbascum phœniceum, the charming Oxalis enneaphylla, with white flowers and grey foliage, from the Falkland Isles; the crimson Silene Asterias, Cypripedium montanum and C. Calceolus, a fine form of Anthericum Liliago, Alyssum saxatile citrinum, Mertensia ciliata (pale blue, 2 feet high), Saponaria Weinmanniana, the yellow Linum arboreum, Delphinium trollifolius, Polemonium cœruleum, the rose-coloured Lychnis Sartorii, and Achillea ageratifolia. In the herbaceous garden Lathyrus filiformis, a native of Southern Europe, a foot in height, with lavender-purple flowers, was pretty, and the giant Ornithogalum lacteum was imposing. In the temperate house Echium Wildpretii was bearing its handsome

FIG. 182.—BULBOPHYLLUM ORTHOGLOSSUM: FLOWERS GREENISH, TINGED AND STRIPED WITH RED-BROWN

flower-spikes, Elæocarpus cyaneus, with white fringed blossoms, followed by blue berries, was attractive, and the rare, white-flowered Cantua pyrifolia showed to advantage, while on the pillars the brightly-coloured Lathyrus splendens and the lavender-flowered L. pubescens were in fine bloom. *S. W. Fitzherbert.*

FORESTRY.

THE CORSICAN PINE.

YOUR correspondent, who, in the number of June 13, discussed *Planting Failures*, attacked the Corsican Pine, under the name of "Corsican fir," by placing it "at the very bottom of the list as a bad transplanter between November and April." He added praise of the Austrian Pine, apparently in this connection. My own experience is so entirely opposite, that I think it worth noting that results, described by me in the *Field*, some years ago, as obtained with Corsicans, upon dry-blown sand in Surrey, continue to hold good. I have twice lost by drought a large number of nurserymen's Austrians, transplanted, no doubt, somewhat too old, but Corsicans transplanted at the same age, as well as in smaller sizes, have invariably succeeded, and have, from the first, made growths averaging 2 feet a year, and sometimes reaching 3 feet for several years in succession. They are, with Cupressus Lawsoniana glauca, by far the most successful trees that I have tried for over 22 years in bad soil. The Austrians are by far the worst with me. The Scotch do badly in a dry year (and we have the least rainfall in England), and are not safe except in shade, while the Corsicans have stood, as have the blue variety of Lawson's Cypress, in the full sun. I have now learned that in planting Scotch in the open it "pays" to give them the shelter of a sandbank on the southern side. Corsicans do without a bank. It would be useless, in my sands, to plant "between April and the end of May." *Charles. W. Dilke.*

THE BULB GARDEN.

PARENTAGE OF NARCISSUS KING ALFRED.

MORE than 22 years ago (April, 1886), by special desire, and after a sitting of the Daffodil Committee, I visited the chambers at Lincoln's Inn of the late Mr. John Kendal. This gentleman was anxious to chat about Daffodils, for he was a great enthusiast, and at the time was forming a collection at his garden in the West of England. In the previous year, 1885, he had obtained bulbs of N. maximus longivirens, and was anxious to raise a good yellow Daffodil from seeds. That day the Daffodil Committee conferred the name on the well-known "Golden Spur" variety, and I related to Mr. Kendal the discussion which took place on its naming. It was at first suggested by most of the committee that "Golden Spur" was the same as Ard Righ, and I maintained that it was not. Mr. Kendal said, "I must have some bulbs of 'Golden Spur.' When will you send them to me?" I told him in the autumn. He then stated that N. maximus should make a good cross with Golden Spur, and I agreed. From this I suspect the parentage of King Alfred to be N. maximus and Golden Spur. *Wm. Baylor Hartland.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

THE BAMBOO GARDEN AT KEW.—Mr Bean, writing in the *Kew Bulletin* No. 6, of last year, on "The Flowering of Cultivated Bamboos," is without information, which perhaps I may be allowed to supply. He says: "The formation of the Bamboo garden at Kew in the winter of 1901-2 not only marked the beginning of a more general cultivation of these plants in Britain, it helped largely to bring it about. It was the first, and still remains the most important, collection open to public inspection." It might be assumed from this that Mr. Bean supposes the Bamboo garden at Kew to be the original in ornamental treatment of a collection, and that no considerable influence had previously been exercised from any other garden open to the public. The facts of the case, however, are quite different. A garden partly for Bamboos was made at Cambridge about 10 years before the present Bamboo garden was made at Kew, and I remember very well the remarks made upon it by Mr. Watson, the present curator at Kew. He regarded this new idea as a good one, and he took great interest in its development at Kew. The few hardy Bamboos then at Kew were planted in a dry position, where they made little growth, whilst the collection at Cambridge was planted ornamentally near water. I have, therefore, always supposed that Cambridge started the modern interest in Bamboos as forming a decorative collection in

gardens, although the fine collection subsequently formed at Kew naturally did far more to popularise these plants. One never quite knows what may be happening elsewhere at the same time, or independently afterwards, but I believe it is a fact that neither Bamboos nor water-plants were usually regarded as ornamental collections in 1881. While original in its treatment of Bamboos, it may be of interest to point out that Cambridge was also original at the same time in the ornamental free-ground treatment of its scientific collection of water-plants. I have always believed that this treatment led very largely to the present popular interest in the cultivation of this class of plants. Undoubtedly it had a very important influence, and in early years, so far as I am aware, there was no other collection treated in the same way. While referring to Cambridge features, it may be worth while to mention the lead made in the cultivation of outdoor Cactaceæ, which at the present moment remain, I believe, the finest to be seen anywhere in Britain. It has also a lead in the cultivation of certain Bromeliaceæ out-of-doors, and there are exceptional features, too, in the number of Crinums and Zingiberaceæ, all grown in the shelter of plant-house recesses. The Bromeliaceæ include a Puya chilensis (single crown) 5 feet high and 5 feet through; Rhodostachys pitcairniifolia (many crowns), together 3 feet 6 inches across and 2 feet high; R. littoralis, 3 feet across and 2 feet high; and Greigia sphacelata, 3 feet high and 4 feet across. Referring again to Bamboos, it may be of interest to mention that last year the Cambridge collection was replanted in a new position, in order that it might further develop and retain something of its former importance. *R. Irwin Lynch, Botanic Gardens, Cambridge.*

NEW MELONS (see p. 350).—I would advise the Council of the Royal Horticultural Society to delete the clause in Regulation 38 referred to by *D.*, at p. 350, from the next issue of its list of rules and regulations. It is asking too much in requesting the raisers of new Melons to send seed of novelties to the Royal Horticultural Society for trial at Wisley prior to the ripe fruit being submitted to the Fruit Committee for its opinion. I fail to see what good could result from compliance with this unreasonable request on the part of the Council of the Royal Horticultural Society, seeing that all that it is necessary to know about the quality of a new Melon—flavour, size and shape—can be ascertained and determined when cut and tasted by the members of the Fruit Committee sitting in the Society's hall. The constitutional and cropping qualities of the new Melons need not be considered by the Committee in making an award, as experience goes to show that plants of old and new varieties of the Melon crop freely enough under ordinary cultural treatment. With all due respect to the capable and able management of the Royal Horticultural Society's gardens at Wisley, I question whether the quality of the fruits resulting from the seed of new Melons sent to Wisley for trial and subsequently submitted to the Fruit Committee would be equal in point of flavour to that possessed by fruits sent up at the same time by the raisers of the respective seedlings. I repeat that it is asking too much of raisers of new Melons to submit seed of the same to the cultural treatment of the Society's staff at Wisley, with the remote chance of subsequently receiving an award from the Fruit Committee. Flavour should be a sine quâ non in determining an award. According to the Royal Horticultural Society's existing clause (indicated at p. 350), the expert in the production of new Melons is placed at a disadvantage. Does the clause in Regulation 38 also apply to the raisers of new Grapes, Peaches, Plums, &c., namely, that they must send plants to Wisley for trial before an award can be made. *Pro Bono Publico.*

THE HARDINESS OF CERTAIN SHRUBS.—After giving a lecture on "Hardy Trees and Shrubs" on April 21 last, I was much impressed with a discussion that arose on the hardiness of certain shrubs, notably Desfontainia spinosa, which was stated by some of the members to have withstood several winters uninjured in the Guildford district. In speaking of the hardiness of certain shrubs, such as Escallonias, Desfontainia, &c., it must be remembered that it is not so much the latitude and longitude of the district that are the determining factors, but the variations of temperature throughout the year, rainfall, freedom from spring frosts, and other items that go to make up what is usually termed a genial climate. A considerable difference may often be found in the same latitude in places that are not many miles apart. For example, this district is a cold one in winter, and we suffer practically every May from frosts of varying severity. Kew Gardens, Haslemere, and Guildford are in practically the same latitude, and within a radius of 30 miles, and many shrubs thrive outdoors in suitable spots that are a failure here, yet the mean temperature of these places is higher than that at Bagshot. Broadly speaking, a line drawn from north to south through the centre of England from Berwick-on-Tweed to Poole in Dorset divides the warm western half from the colder eastern half of the country. But this division is a purely arbitrary one, as parts of Lancashire, Cheshire, Shropshire, and Worcester are not as warm as Hampshire, Sussex, and Kent. In speaking, therefore, of the hardiness of various shrubs in certain localities it must always be borne in mind that climatic conditions are very variable in this country, even within a comparatively small radius. I have always disagreed with the old dictum that certain plants require a sheltered position, as I have found by experience that shrubs which are generally regarded as tender withstand severe weather better when they are fairly exposed. Shelter from the morning sun is necessary, as a quick thaw after a frost often damages a plant that would be scarcely injured if allowed to thaw gradually. The side of a hill facing west or south-west is an ideal spot for tender shrubs, as the hill shelters them on the east, and they are also in the position for receiving the full benefit of the sun during the greater part of the day. There is one way in which many plants can be made hardier, and that is by raising them from seeds ripened in this country. This is being done by a few persons, but if it was generally practised much might be done towards making these shrubs of a hardier constitution. This is shown in the Laurel (Prunus Laurocerasus) and the Aucuba. These, when first introduced, were found somewhat tender, but when raised from seeds ripened in this country they were found to be much hardier. Some shrubs usually considered on the tender side are found to be hardy in unlikely places, and this is possibly the reason. *J. Clark, Bagshot, Surrey.*

SPRING FROST IN WESTERN SCOTLAND.—By a slip of the pen I wrote of the frost of April 24 last having proved more destructive than any since May, 1907. Of course, I intended to write 1887. Lomatia ferruginea may be added to the list of shrubs which suffered no injury in the open. *Herbert Maxwell.*

NEW COLOURS IN WALLFLOWERS. — The Wallflower has, up to the present, gained nothing from recent introductions of new colours, but, on the contrary, it has suffered depreciation. The mixed patches of washed-out shades of red, purple, pale yellow, brown, and mahogany are very poor substitutes for the time-honoured fragrant masses of dark brown and bright yellow. The change is, perhaps, chiefly noticeable in cottage gardens, whose owners have (temporarily, I hope) too easily parted with one of the chief glories of the year. Of the newer colours the sulphur-yellow is pretty, especially in a partially shaded site; but nothing can equal masses of a good dark form of the (so-called) "Blood Red" and a bright yellow variety, such as Cloth of Gold. *Harold Evans, Cardiff.*

SOCIETIES.

ROYAL HORTICULTURAL.

COLONIAL EXHIBITION.

JUNE 11, 12.—An exhibition of Colonial fruits, &c., was held under the auspices of the Royal Horticultural Society at the Society's Hall, Vincent Square, on these dates. Australia and New Zealand were extensively represented in exhibits of Apples, Pears, and preserved fruits, and the West Indies by a quantity of tropical fruits, yams, liquers, sugar and by-products of the sugarcane, &c. It was remarked how splendid in size, colour, and general good quality appeared the numerous varieties of Apples from New Zealand and Australia. Most of the varieties were of English origin, although scarcely recognisable as such, and others were from America.

In the New Zealand exhibit very fine were Tasmanian Blenheim Orange, a greenish-yellow fruit destitute of russet colouring; Guntip's Seedling, a highly-coloured fruit, in shape like an enlarged Cox's Orange Pippin; Munroe's Favourite, a large yellow and pink-coloured fruit; Prince Alfred, &c. (Gold Medal.)

A Silver Knightian Medal was awarded G. ANDERSON, Esq., Adelaide, for South Australian fruit (Karrosa Brand). The London agents are G. S. Yuill & Co., Ltd., 120, Fenchurch Street, E.C. We noted Cleopatra (syn. New York Pippin) and Jonathan (both are dessert varieties), Rome Beauty, Dunn's Seedling, and Œsopus Spitsbergen. The fruit was high in colour and over-ripe.

H. C. WILLIAMSON, Esq., Melbourne, received a Bronze Banksian Medal for four cases of Apples. They were packed in boxes in layers of 30 fruits, as was general with all the Australian Apples.

Mr. E. BLAKENAY, Christchurch, New Zealand, South Island, displayed Apples and Pears, for which a Silver-Gilt Banksian Medal was awarded.

Fruit preserved in tins and bottles came from the WESTERN PROVINCE PRESERVING CO., South Africa. (Silver Knightian Medal.)

Messrs. R. JACKSON & Co. were awarded a Silver-Gilt Knightian Medal for preserved fruits in bottles, jars, and tins. Besides the commoner kinds of fruit, there were noted Cape Gooseberry jam, Guava jelly and jam, and mixed green Apricot and ripe Peach jam.

A Silver-Gilt Knightian Medal was awarded to Messrs. J. SEDGWICK & Co., of Cape Town, for wines and liqueurs.

A Silver-Gilt Banksian Medal was awarded the DOMINICA FRUIT GROWERS' ASSOCIATION for a large exhibit of Limes.

A Silver-Gilt Knightian Medal was awarded to Messrs. E. WESTMACOT & Co., 180, Leadenhall Street, London, E.C., for an exhibit of Cape wines, tobacco, preserves, &c.

The WEST INDIAN PRODUCE ASSOCIATION, LTD., 4, Fenchurch Buildings, London, E.C., and West Indies, made an exhibit of Natal tea, Pineapples, Oranges, Shaddocks, sauces, Capsicums, Bananas in variety, sweet Potatos, Limes and limejuice, ripe Mangos, honey, ginger, tobacco, &c. (Gold Medal.)

Messrs. T. RIVERS & SON, Sawbridgeworth, were awarded a Silver-Gilt Knightian Medal for an exhibit of fruit trees in pots, and Messrs JAS. VEITCH & SONS, LTD., Chelsea, a Silver Knightian Medal also for fruit trees in pots.

Scientific Committee.

JUNE 9.—*Present:* E. A. Bowles, Esq., M.A., F.L.S., F.E.S. (in the chair); Dr. M. C. Cooke, Dr. A. Voelcker, Messrs. A. W. Sutton, J. T. Bennett-Poe, W. Cuthbertson, H. T. Güssow, G. S. Saunders, W. Hales, W. C. Worsdell, E. M. Holmes, de B. Crawshay, J. W. Odell, and F. J. Chittenden (secretary).

Brugmansia leaves injured.—Mr. GÜSSOW reported that he had examined the leaves of Brugmansia shown at the last meeting by Mr. SAUNDERS, and found that they had been injured by some insect which had punctured the leaf, and around this puncture corky cells had developed.

Malformed Orchids.—Mr. W. C. WORSDELL reported that he had examined a specimen of Cattleya intermedia referred to him in which three flowers had become fused together so that there were eighteen perianth pieces in the resulting fasciated specimen and three properly formed columns. The ovaries, however, were completely absent. Mr. GURNEY WILSON, of Glenthorne, Haywards Heath, Sussex, sent flowers of Odontoglossum crispum which were referred to Mr. WORSDELL.

Oxalis bupleurifolia. — Mr. W. HALES, showed the interesting Oxalis bupleurifolia, a Brazilian species with small yellow flowers, having the petioles developed into phyllodes, which are remarkable in being placed horizontally instead of vertically, as in most plants possessing phyllodes. In several cases

the phyllodes possessed at their tips the three leaflets normal in species of Oxalis, though occasionally the terminal one was represented only by a small linear outgrowth, and sometimes all were absent. These leaves are sensitive to contact. The plant grows in shady woods in Brazil, which probably accounts for the horizontal position of the phyllodes.

Malformed Streptocarpus.—Mr. J. W. ODELL, showed very fine flowers of Streptocarpus having in some cases two linear petaloid outgrowths arising between the calyx and the corolla on the dorsal side of the flower, in others stamens were produced in this position. Mr. ODELL found that the later produced flowers bore stamens, while the first flowers had the petaloid outgrowths. He had seen similar growths in Gloxinia, and in the present case he removed the first developed flowers as soon as the petaloid outgrowths were noticed, and the flowers next produced developed stamens in the position occupied by the outgrowths in the first produced flowers.

Rosa lutea.—In June, 1906, Mr. A. W. SUTTON, F.L.S., showed before the Committee dried specimens of a yellow Rose which had been named at Kew Rosa Eglanteria (= R. lutea) from Baalbec. Mr. SUTTON subsequently obtained through a lady missionary at Baalbec some pods and shoots of this Rose, but they were dead when they arrived. Later, however, he received other seeds, from which three plants had been reared, and which were now flowering in his garden. He exhibited a flower of a beautiful clear yellow colour, measuring 3 inches in diameter. A full account of the history of this plant, which Colonel PRAIN thought when he saw the dried specimens from Baalbec to be identical with the Indian Rose Eglanteria, is given in the *Gardeners' Chronicle*, July, 1906.

Yellow stripe in Daffodils.—Specimens of this well-known disease were received, and some discussion took place concerning it. Various members of the Committee detailed their experiences concerning it, and regarded as contributory causes the use of fresh manure, late planting, and too wet a soil. The precise primary cause is at present unknown, but, as Mr. DARLINGTON suggested in his lecture at the general meeting, imperfect root action may be a cause, but whether primary or secondary is not clear.

Abnormal Daisy.—Mr. A. W. SUTTON showed an abnormal Daisy having the head inverted so that the florets pointed downwards instead of upwards as in the normal inflorescence; while the stalk passed completely through the centre of the head and was attached at the upper side where there were the usual bracts forming the involucre, but in this case occupying the upper portion of the inflorescence.

CHESTERFIELD CHRYSANTHEMUM.

JUNE 8.—The spring show of this Society was held on the above date at Wingerworth Hall, Chesterfield.

Mr. Nelson, gardener to A. T. H. BARNES, Esq., of Ashgate Lodge, put up an excellent exhibit of flowering and foliage plants, and also well-fruited Strawberries in pots. H. WESTLAKE, Esq., Brimington Hall (gr. Mr. Boult), had a fine display of well-grown Calceolarias, Schizanthus retusus, S. Wisetonensis, &c. J. E. CLAYTON, Esq., Thornfield (gr. Mr. Dent), staged a group of plants of considerable merit. Mr. W. Parks, gardener to Rev. H. N. BURDEN, of Whittington Hall, also arranged an attractive group of plants. Mr. Bloxham, gardener to R. F. MILLS, Esq., Tapton Grove, made a fine display of hardy flowers in variety. The president's gardener, Mr. LOVATT, showed table decorations, as also did Mr. Money, gardener to Dr. BOOTH, Chesterfield.

BRITISH GARDENERS' ASSOCIATION.

JUNE 9.—At the last meeting of this association, Mr. E. F. Hawes, Superintendent of the Royal Botanic Society's Gardens, Regent's Park, was elected chairman of the executive council for the ensuing year, and Mr. Chas. Foster, vice-chairman for the same period.

Nineteen new members were elected, bringing the total up to 1,308. Messrs. Hawes, Foster, Winter, Castle, Raffill, and Weathers were appointed on the publication committee. *J. W.*

YORKSHIRE GALA.

JUBILEE EXHIBITION.

JUNE 17, 18, 19.—The management must be congratulated on the great success attending their efforts to make this, their jubilee show, a record one, but they are to be commiserated in that their efforts were so largely negatived by the unpropitious weather conditions which obtained on the opening day. The rain was torrential and in addition it was cold, so that the attendance was meagre, and a gloom was in consequence cast over the show. Inside the tents, however, there was seen a bright floral display, and never before in the history of the York Society has so meritorious an exhibition of horticultural products been gathered together. The show attracted most of the best cultivators in their various sections, and in addition the function was honoured by a deputation from the Royal Horticultural Society, consisting of the president, Sir Trevor Lawrence, Bart., Rev. W. Wilks (secretary), J. Gurney Fowler, Esq. (treasurer), Sir Albert Rollit, and Messrs. H. J. Veitch and H. B. May. The premier Society granted many medals and cups, a list of the winners being given at the end of the report. Special attention may be directed to the many fine groups of plants in the competitive classes, the Orchids from Westonbirt and elsewhere, the collections of vegetables and arrays of hardy garden plants. That the adverse weather experienced this year is no new feature at the York Shows may be seen from the following extract taken from the official account of the Society's history: "The Society has always had one persistent and implacable enemy—the weather."

SPECIAL JUBILEE CLASSES.

In order to commemorate the 50th year of the Society, the management provided four special classes, in which were offered prizes of considerable value. The first was for a festal display of plants and flowers, grouped for effect, and occupying an area of 30 feet by 14 feet. There were three contestants, the 1st prize being won by Mr. W. A. HOLMES, West End Nurseries, Chesterfield, but he was very closely followed by Mr. JOSEPH PICKERSGILL, Bardon Hill, Weetwood, Leeds (gr. Mr. J. Donoghue), and very few points must have separated the two competitors. The groundwork of the premier exhibit was especially handsome, and in addition the plants were remarkably well cultivated. Codiæums, Caladiums, Coleus, Begonias, Dracænas, Saxifragas, Acalyphas, Abutilons, and other similar plants were all of remarkably fine colour, whilst Roses, Orchids, Liliums, Verbenas, Carnations, Kalanchoe flammula, and many other pretty flowers added an additional touch of colour. Tall plants of Rambler Roses, Codiæums, epergnes of Carnations, Cocos Palms, &c., were disposed with taste and good judgment in the display. The exhibit from JOSEPH PICKERSGILL, Esq., was a charming group, having at the back Rambler Roses in variety, intermingled with Palms, &c. Two hanging pillars, covered with Vitis Henryana and supporting at their extremities baskets of Odontoglossum crispum, were not the least pleasing features. 3rd, Mr. WM. VAUSE, Warwick Street, Leamington.

The next special class was one for a display of garden products arranged for effect and instruction, occupying an area of 20 feet by 6 feet. There were three groups, but we were not greatly impressed with either. The 1st prize group, shown by CHAS. E. SIMPSON, Esq., York (gr. Mr. F. Nutbrown), had many stiff formal floral devices, with an assortment of flowering and foliage plants, also fruits in variety, such as Grapes, Melons, Peaches, Pineapples, Cherries, &c. The 2nd prize was won by Messrs. W. ARTINDALE & SON, Sheffield. This firm did not include fruits in their group, but they had many choice cut flowers, and several imposing floral devices. 3rd, Messrs. J. BACKHOUSE & SON, LTD., York.

Another of these special classes was for an exhibit of bulbous and allied plants, also cut flowers associated with retarded plants. This met with a poor response, only one display being forthcoming. It was shown by Messrs. WALSHAW & SONS, The Nurseries, Scarborough.

A special class was also provided for a display of produce from Yorkshire gardens only, and again only one group was staged. This was from the gardens of Lord LONDESBOROUGH, Londesborough, Market Weighton (gr. Mr. J. C. McPherson). One portion of the exhibit consisted of a collection of fruits—Peaches, Nectarines, Grapes, Figs, Melons, Cherries, &c., and at the other end was a display of vegetables, with vases of Sweet Peas, Schizanthus, &c., separating the two. The background was of ornamental-leaved plants, with Schizanthus Wisetonensis intermixed.

GROUPS OF PLANTS.

An important class was one for a group of miscellaneous plants, flowering or otherwise, and arranged for effect, the allotted space being 300 square feet. This formed a fine feature, there being five groups, all of choice quality and well arranged. A bold design was attempted by Mr. Skinner, gardener to J. W. COULTHURST, Esq., Gargrave House, Leeds, and he was worthily awarded the 1st prize. A feature was introduced in the foreground in a water scene, and another character was a mossy groundwork, amongst which moss-covered branches were introduced. Handsome columnar-trained Roses, tall Codiæums (Crotons), Humea elegans, a fitting background well disposed, and bright flowering plants at intervals, formed the general design. The 2nd prize was awarded to Mr. JOE S. SHARP, Valley Nurseries, Huddersfield, and although the design was quite different to the foregoing it appealed strongly to one's sense of the artistic. It included plants of a highly decorative character, all shown in fine form. 3rd, JAMES BLACKER, Esq., Thorpe Villas, Selby (gr. Mr. Walter Curtis).

Nine stove or greenhouse plants.—Large specimens of Ixora Fraseri, I. Pilgrimii, Clerodendron Balfouri, Erica ventricosa magnifica, E. Cavendishii, Francisca eximea (a handsome specimen), and Anthurium Scherzerianum obtained the 1st prize for Messrs. JAMES CYPHER & SONS, Cheltenham. 2nd, Mr. W. VAUSE, Leamington. Messrs. CYPHER were also successful in the class for six stove or greenhouse plants, and Mr. VAUSE again followed.

In the class for three stove or greenhouse plants the order of these exhibitors was reversed, with Mr. JAMES SUNLEY, Ashleigh, South Milford, 3rd.

Messrs. CYPHER & SONS showed the best single specimen of a greenhouse plant in flower.

In the class for six fine foliage or variegated plants, to include two Crotons, the winning exhibit was displayed by Mr. JOE S. SHARP. Mr. W. VAUSE excelled with three ornamental-leaved or variegated plants.

Carnations.—A well-grown collection of Carnations was exhibited by Mr. J. PICKERSGILL, Bardon Hill, Leeds, the exhibit being awarded the 1st prize. 2nd, Messrs. WALSHAW & SON, Scarborough. 3rd, Mr. J. E. SKAIFE, York.

Cannas.—These flowers were not largely shown, and in the class for a group not exceeding 12 feet by 5 feet, Mr. W. LANGSTAFFE, York, received the 1st prize, and Messrs. WALSHAW & SON, Scarborough, the 2nd prize.

Gloxinias.—For a group of Gloxinias in bloom, arranged for effect with foliage plants or Ferns, the 1st prize was awarded to Sir J. GRANT LAWSON, York (gr. Mr. J. Dobson), for an excellent exhibit of well-flowered plants. The 2nd prize was awarded to RICHARD LAWSON, Esq., York, who had a choice display. 3rd, Messrs. SEAGRAVE & Co., Sheffield.

Begonias.—A class was provided for a group of tuberous-rooting Begonias in flower and arranged for effect. This was well contested, resulting in Mr. F. STYAN, Clifton, York, winning the 1st prize with a good display well arranged. 2nd, Mr. S. LEETHAM, The Mount, York. 3rd, Mr. SCHMIDT, Fulford, York, who had many good flowers, but they were rather flat in arrangement.

Calceolarias.—There were four exhibits of these flowers. Much the best, and to which the

1st honours were awarded, was shown by Mrs. VON BEVERHOUDT, Elvington Hall, York (gr. Mr. H. Mason). 2nd, GEORGE LEE, Esq., York.

Pelargoniums.—In a class for six double-flowered Pelargoniums of distinct varieties, Mr. F. W. CROWTHER, York, was awarded the 1st prize, Mr. J. W. CLARKE, York, the 2nd, and Mr. HENRY PYBUS, Leeds, the 3rd prize; whilst for three double-flowered Ivyleaved Pelargoniums Mr. JOHN R. WEDGWOOD, York, was placed 1st; 2nd, Mr. HENRY PYBUS.

In a class for a group of show Pelargoniums in flower and arranged for effect with foliage plants or Ferns, to occupy a space not exceeding 8 feet by 5 feet, there were five exhibitors. Mr. J. E. SKAIFE, York, won the 1st prize with a well-arranged group, and Mr. W. LANGSTAFFE, York, the 2nd prize.

For an exhibit of six Pelargoniums Mr. GEO. LEE was awarded the 1st prize; 2nd, Mr. J. E. SKAIFE.

A good exhibit of 12 Zonal Pelargoniums, of a type suitable for buttonholes, &c., was staged by HENRY PYBUS, Esq., Monkton Moor, Leeds, and it received the 1st prize. Second honours fell to JAMES SUNLEY, Esq., Ashleigh, South Milford.

Fuchsias.—A pleasing group of Fuchsias in flower and arranged for effect with foliage plants and Ferns was shown by Mr. W. KETTLEWELL, York, and in a class allotted to these flowers it received the 1st prize. The 2nd prize was won by Mr. J. W. CLARKE, Clifton, York.

ORCHIDS.

There were many choice groups of Orchids, and several classes were provided for them. Chief honours must be given to Lt.-Col. HOLFORD, Westonbirt, Tetbury, Gloucestershire (gr. Mr. Alexander). He had many of his magnificent hybrids and varieties, all exhibiting the high standard of culture for which his plants are famed. We may instance a fine specimen of Miltonia vexillaria, Thunia Marshallii, with 60 flowers; Dendrobium Dalhousianum nobile, having six spikes of bloom; Miltonia vexillaria var. Chelsiensis, with 13 spikes carrying 53 flowers; Cattleya Dusseldorfei "Undine," Lælio-Cattleya Canhamiana, having two spikes bearing altogether 250 flowers; Odontoglossum crispum in numerous choice forms, Lælia tenebrosa Walton Grange variety, Brasso-Cattleya Striata, a magnificent plant; Cattleya gigas, having six flowers on one spike; Dendrobium Wiganiæ xanthochilum, Brasso-Cattleya Digbyano-Mendelii, Dendrobium Dalhousianum luteum, Vanda teres, Cochlioda Noezliana, with very fine flower spikes; Cattleya Whitei splendissima, a plant of Miltonia vexillaria bearing altogether 130 spikes, and Odontoglossum citrosmum having 12 spikes with 202 flowers.

A collection of twelve Orchids.—This class was contested by two exhibitors, the class being open to amateurs only. Lt.-Col. HOLFORD (gr. Mr. Alexander) had the better dozen, and was awarded the 1st prize, his plants being Dendrobium Dalhousianum nobile, Miltonia vexillaria Chelsiensis, M. v. Empress Augusta, Lælio-Cattleya Chamiana, L.-C. Martinettii Flambeau, Cattleya Dusseldorfei var. Undine, C. Whitei splendissimum, C. fulvescens, C. gigas, C. Mossiæ Wageneri, O. crispum Erebus, and Cypripedium callosum Sanderæ. All were alike good and deserving of the highest commendation. The other exhibitor in this class was W. P. BURKINSHAW, Esq., West Hill, Hessle (gr. Mr. J. T. Barker). He had some well-grown specimens, including Cattleya Mme. Myra Peeters, Brasso-Cattleya Digbyano-Mossiæ, C. Mossiæ Reineckiana, Lælio-Cattleya Canhamiana alba, L.-C. fascinator, L.-C. Eudora Princess Ena, Vanda Imschootiana, and Cypripedium niveum.

A class was provided for a table arranged with Orchids, and measuring 12 feet by 5 feet. There were three competitors, and so excellent were two that the judges awarded them equal 1st prizes. These were shown by Messrs. J. MOORE, LTD., Rawdon, Leeds, and Messrs. J. CYPHER & SONS, Cheltenham. Messrs. MOORE showed some very good plants of Odontoglossum crispum, Brassavola Digbyana, Vanda suavis, Cypripedium bellatulum, C. callosum Sanderæ, Lælia majalis, Sobralia macrantha, Lælia-Cattleya Eudora, Cattleya Mendelii, Epidendrum aromaticum, Oncidium pumilum, Vanda Bensoniæ, Anguloa Clowesii, Promenæa citrina × P. Stapelioides, Maxillaria tenuifolia, Cœlogyne pandurata, &c. Messrs. CYPHER had Miltonia vexillaria in fine condition, Dendrobium atro-violaceum, D. Dalhousianum luteum, D. clavatum, Oncidium papilio, Cypripedium callosum Sanderæ, Odontoglossum crispum with five flower spikes, O. Pescatorei, Lælia purpurata, Oncidium leucochilum, and Lælio-Cattleya Canhamiana.

Amongst the non-competitive exhibits was a grand display of Orchids shown by Messrs. CHARLESWORTH & Co., Heaton, Bradford, who filled the space they usually occupy at this show with a miscellaneous collection, including Cattleya Mendelii alba, having pure white petals and sepals and a light rose-coloured lip; C. Mossiæ Wageneri, a home-raised seedling; Dendrobium regium, Lælio-Cattleya King Edward VII., a fine large flower with very dark richly-coloured lip; Miltonia vexillaria alba, Odontoglossum amabile, O. Phœbe var. splendens, Lælio-Cattleya Canhamiana in variety, L.-C. fascinator, Phalænopsis Rimestadtiana, &c.

There were other exhibits of Orchids, amongst which may be mentioned a remarkable plant of Dendrobium thyrsiflorum, having ten excellent inflorescences, shown by Miss BARSTOW, Garrow Hill, York (gr. Mr. T. Douthwaite); and a plant of Dendrobium densiflorum, with ten flower spikes, shown by R. J. FOSTER, Esq., Stockeld Park, Wetherby (gr. Mr. J. Turton).

ROSES.

The principal class for a collection of Roses in pots and cut blooms was that in which a table space of 18 feet by 5 feet was allowed. There were four groups in all, the whole of them being arranged on tables. The 1st prize was won by Mr. GEO. PRINCE, Longworth, Berks, who showed a number of single blooms of good quality in boxes, with vases and epergnes filled with garden varieties at the back. The adjoining exhibit put up by Messrs. W. & J. BROWN, Peterborough, received the 2nd prize, the blooms being very fresh and bright in appearance. 3rd, Mr. GEO. MOUNT, The Nurseries, Canterbury, who had excellent blooms, but of fewer varieties.

A group of Roses occupying 15 feet by 7 feet.—The groups in this class were arranged on the ground, and in each case were semi-circular in form. There were five groups shown, the best being arranged by Mr. J. E. SKAIFE, Burton Lane, York, who showed healthy plants with rather full blown flowers. Use was made of Rambling varieties to break the formal appearance of the group. 2nd, Mr. WM. TODD, 19, Vyner Street, York, with a rather thin exhibit: the plants gave promise of abundant flowering later; the few flowers developed were of good quality. 3rd, Mr. GEO. MOUNT, Canterbury, who largely utilised Rambler Roses.

Group of Roses with decorative plants.—Three somewhat stiff groups, and one mainly of Rambling varieties, formed the complement of exhibits in this class. The 1st prize was awarded to the exhibit presenting the most blooms, and consequently the brightest in colour. It was shown by Mr. W. LANGSTAFFE, 16, Sydney Street, York. 2nd, Mr. J. E. SKAIFE, Burton Lane, York.

Cut blooms.—The classes for cut Roses were well represented, but generally the quality was not very good. In the important one for 72 blooms, there were three exhibits. The decision was in favour of Messrs. D. PRIOR & SONS, Colchester, who had a fairly good display, considering the earliness of the season, notable blooms being Madame Gravereaux, Maréchal Niel, Captain Hayward, White Maman Cochet, Frau Karl Druschki, Lady Mary Fitzwilliam, &c. We could find no 2nd prize exhibit, but the 3rd was awarded to Messrs. B. R. CANT & Co., Colchester, some of the best flowers being those named after Mrs. Ed. Mawley, Maman Cochet, Frau Karl Druschki, White Lady, and Souvenir d'Un Amie.

Forty-eight blooms of Roses.—There were four competitors in this class, much the best collection being shown by Mr. GEO. MOUNT, Canterbury. He had Aimee Cochet, Rev. Allen Cheales, Richmond (of exquisite colour), Mildred Grant, Mrs. John Laing, Frau Karl Druschki, &c. 2nd, Messrs. D. PRIOR & SONS, Colchester.

Thirty-six blooms of Roses.—The best of six exhibits was that put up by Messrs. HARKNESS & SONS, Hitchin. There were some choice blooms in this exhibit, notably Wm. Shean, Dean Hole, Lady Ashtown, White Lady, Mrs. Ed. Mawley, Ulster, Killarney, and Mrs. David M'Kee. 2nd, Messrs. D. PRIOR & SONS.

ROCK GARDEN EXHIBITS.

The schedule required a naturally-arranged exhibit of hardy herbaceous and perennial plants and flowers, with a pool of water for the inclusion of water-loving plants. There were five displays, and they required the whole side of one of the large tents for their accommodation. The exhibits were all good, but the chief competition was between Messrs. J. BACKHOUSE & SON, LTD., York, and Messrs. WM. ARTINDALE & SON, Sheffield: the judges decided in favour of the former firm. The stone-work was massive in its proportions, several tons of solid sandstone being employed. As to the arrangement, nothing but praise can be bestowed, for so realistic did the exhibit appear it might have existed for years. One corner, cleverly arranged, had a dripping pool, which wandered along the whole front, all tastefully planted with Nymphæas, Irises, Aponogeton, and other water-loving subjects. Ferns peeped from the recesses of the rock, and other parts had an admirable assortment of Alpine plants cleverly disposed. Room was found for a bog garden at one end, in which hardy Cypripediums, Primulas, &c., appeared to revel. Some of the "bluffs" were topped with dwarf Conifers, and up the sides scrambled Saxifragas, Veronicas, Helianthemums, Gentians, Dianthus, and other subjects. The 2nd prize, as stated, was awarded to Messrs. ARTINDALE for a bold design, very rich in flowering plants, and containing not a few novelties. The background was formed of tall Eremurus, Delphiniums, Aquilegias, Liliums, &c., with many Rhododendrons covered with their stately blooms. 3rd, Mr. J. WOOD, Boston Spa, York.

Ferns.—The only class for Ferns was one for six hardy Ferns of distinct varieties. Mr. J. ARCHER, York, won the 1st prize with six good specimen plants in 15-inch pots. 2nd, Messrs. R. SIMPSON & SON, Selby.

FRUIT CLASSES.

Decorated tables of ripe fruit.—This class brought good competition, and attracted some noted fruit growers, the exhibits generally being of a high order of merit. Amongst keen competition, the Duke of PORTLAND, Welbeck Abbey (gr. Mr. J. Gibson), carried off the premier prize with a beautiful exhibit of high-class produce, well arranged. A central epergne of flowers had on either side a bunch of Grapes of Black Hamburg and Muscat of Alexandria varieties respectively; magnificent Peaches of the Grosse Mignonne variety, Nectarine Cardinal (highly coloured), Cherries Bigarreau de Schrecken and Governor Wood, Strawberry Kentish Favourite, Melon Royal Jubilee, with Plums, Figs, &c., all of the choicest quality. The points awarded were as follow:—Cherries, 11; Figs, 8; Grapes, 6 (weak); Melons, 12 (maximum); Nectarines, 9; Peaches, 12; Plums, 5; Strawberries, 6; beauty of flower and foliage, 6; colour blending, 6; general arrangement, 8; total, 89 out of a possible 136. 2nd, the Earl of HARRINGTON, Elvaston Castle, Derby (gr. Mr. J. H. Goodacre), who had one point less than the 1st prize winner, Nectarines, Peaches, Pineapples, and Figs being his finer dishes. The Nectarines were of admirable quality, and the arrangement left little to be desired. 3rd, the Marquis of NORTHAMPTON, Castle Ashby, Northampton (gr. Mr. A. R. Searle), with 82 points. A bunch of Foster's Seedling Grape was noteworthy in this collection.

COLLECTIONS OF FRUITS.

The schedule required ten kinds, but not more than two varieties of Grapes, in the class for the largest collection. This class brought three contestants, the most successful being the Rt. Hon. Lord LONDESBOROUGH, Londesborough, Market Weighton (gr. Mr. J. C. McPherson). The dishes were Muscat of Alexandria and Black Hamburg Grapes, both of mediocre quality, Lord Napier Nectarine (good), Royal George Peaches, Brown Turkey Figs, a small Orange, Strawberry Royal Sovereign, Early Rivers'

Cherry, and a Queen Pine. The 2nd prize exhibit was from the gardens of the Earl of HARRINGTON, Elvaston Castle, Derby (gr. Mr. J. H. Goodacre). His Black Hamburg Grapes were choice, as were also the Brown Turkey Figs, a seedling Melon, and Lady Sudeley Apples. 3rd, Messrs. COLEBROOK BROS., Burton-on-Trent.

Six kinds of fruits.—Six exhibits were seen in this class, the best being shown by Lord LONDESBOROUGH (gr. Mr. J. C. McPherson). Foster's Seedling and Black Hamburg Grapes, Cardinal Nectarine, Strawberry Leader, a big Melon of the Ringleader variety, and Royal George Peaches were the varieties shown, all good but not of outstanding merit. 2nd, the Rt. Hon. Lady BEAUMONT, Carlton Towers, S.O., Yorks. (gr. Mr. Wm. Nicholls). A grand dish of Transparent Gage Plums was the outstanding feature of this display. 3rd, Messrs. COLEBROOK BROS.

Four kinds of fruits.—This smaller class brought only two groups, although six originally entered. The Nectarines were of remarkable quality in both exhibits, but neither group was adjudged worthy of the 1st prize.

GRAPES, PEACHES AND MELONS.

The best two bunches of Black Hamburg Grapes were shown by Lady HAWKE, Wighill Park, Tadcaster (gr. Mr. Herbert Bray), the berries being large and well coloured; bunches of medium size. 2nd, Lord HOTHAM, Dalton Hall, Beverley (gr. Mr. W. Jackson). The bunches required a little longer time for ripening, when they would have eclipsed those in the 1st prize exhibit. 3rd, Lady BEAUMONT (gr. Mr. Wm. Nicholls).

White Grapes.—The last-mentioned exhibitor was successful in winning the 1st prize with bunches of Buckland Sweetwater, well matched and well ripened. 2nd, larger bunches of the same variety but not quite so well finished, shown by Lord HOTHAM, Dalton Hall, Beverley (gr. Mr. W. Jackson). The Grapes generally were not of outstanding quality and small in bunch.

Peaches and Nectarines.—Col. HARRISON-BROADLEY, M.P., Welton House, East Yorks. (gr. Mr. Chas. Lawton), secured the 1st prize for six Peaches with fruits of Grosse Mignonne, in a strong competition, and the premier award for Nectarines was taken by the Earl of HARRINGTON (gr. Mr. J. H. Goodacre), with superb fruits of Early Rivers.

Melons.—The classes for Melons were strongly contested, and the best scarlet-fleshed variety was shown by Lord ELPHINSTONE, Carberry Tower, Musselburgh (gr. Mr. D. Kidd); the best green-fleshed variety by the Duke of PORTLAND, Welbeck (gr. Mr. James Gibson); whilst the 1st prize for a white-fleshed Melon was awarded to W. C. GRAY, Esq., Tunstall Manor, West Hartlepool (gr. Mr. Thos. Pattison).

VEGETABLES.

For a collection of vegetables of six distinct sorts, grown from seed supplied by Messrs. Webb & Sons, Wordsley, Stourbridge, the 1st prize was won by the Hon. VICARY GIBBS, Aldenham House, Elstree (gr. Mr. E. Beckett), who staged Vegetable Marrow Moore's Cream, Cauliflower Early Mammoth, Carrot Prize-winner, Potato Wordsley Pride, Tomato Sensation, and Pea Stourbridge Marrow. The 2nd prize was secured by the Marquis of NORTHAMPTON, Castle Ashby, Northampton (gr. Mr. A. R. Searle). 3rd, the Earl of LATHOM, Lathom House, Ormskirk (gr. Mr. Ben. Ashton).

Messrs. Sutton & Sons, Reading, offered prizes for similar exhibits grown from their seeds. The 1st prize was won by the Duke of PORTLAND, Welbeck Abbey, Worksop (gr. Mr. J. Gibson), who showed superb samples of Dwarf Bean Magnum Bonum, Cauliflower Magnum Bonum, Carrot Favourite, Potato Gladiator, Tomato Eclipse, and Pea Duke of Albany. The 2nd prize was won by the Earl of LATHOM (gr. Mr. Ben. Ashton), who had also some excellent produce.

Messrs. James Backhouse & Son, Ltd., York, offered prizes for collections of 10 distinct varieties, the 1st prize being won by the Marquis of NORTHAMPTON, Castle Ashby, Northampton (gr. Mr. A. R. Searle). 2nd, P. NEVILLE, Esq., Skelbrooke Park, Doncaster (gr. Mr. J. Newbold).

NON-COMPETITIVE EXHIBITS.

Messrs. JAMES VEITCH & SONS, LTD., King's Road, Chelsea, put up an imposing group of exotic plants, many of which were ornamental-leaved subjects, with here and there a few bright batches of flowering plants and a bank of showy Orchids in the centre. There were examples of the beautiful Dracæna Doucettii de Grootei at either corner, and another feature were tall stands furnished with Asparagus and carrying finely-pitchered plants of Nepenthes. A plant of the handsome Dracæna Victoria found a prominent place in the group, the body of which was composed of choice foliage plants.

Messrs. RICHARD SMITH & Co., Worcester, staged a group of Pæonies and other hardy flowers of a showy character, such as Irises, Pyrethrums, Campanulas, Delphiniums, Anchusa italica, &c. Adjoining their garden flowers Messrs. SMITH displayed an exhibit of greenhouse flowering plants arranged with pleasing effect. Tall vases filled with Carnations were prominent objects.

Messrs. WM. CUTBUSH & SON, Highgate, London, N., staged a handsome exhibit, arranged with the skill for which this firm's groups are noted. They had graceful sprays of Bambusa gracilis and Rambler Roses overhanging a mixed collection of Carnations, dwarf Roses, Hippeastrums of considerable merit, Andromeda speciosa, Astilbe (Spiræa), Metrosideros floribunda, Verbena Princess of Wales and others, yellow-flowered Richardias, &c., all pleasingly relieved with Adiantum Ferns, Codiæums (Crotons), and Dracænas.

Messrs. KER & SONS, Aigburth Nursery, Liverpool, had a fine exhibit of Hippeastrums (Amaryllis), and amongst them were Masterpiece, Monarch, President, The Premier, White Lady, Crimson King, Goliath, and Lady Roberts, the whole well staged and relieved with Ferns.

Opposite their very fine exhibit of a rock garden, Messrs. JAMES BACKHOUSE & SON, York, showed a group of stove and greenhouse plants, principally flowering subjects, amongst which were Hydrangeas, Carnations, show Pelargoniums, Roses, Liliums, Begonias, Rhododendrons, Metrosideros floribunda, with suitable greenery, of which choice varieties of Ferns formed a considerable part.

Messrs. G. LONGSTER & SONS, Derwent Nurseries, Malton, staged a pleasing collection of plants, principally of hardy subjects, the groups being freely relieved with ornamental-leaved plants. Metrosideros floribunda, Pyrethrums in variety, Lobelias in shades of blue, Geums, Carnations, Calceolarias, and Celosias are a selection of the more showy flowers displayed.

Messrs. DICKSONS, Chester, arranged a very large group of hardy flowers. Pæonies formed a large portion of the exhibit, and these embraced most of the varieties of merit. The pale-blue coloured Delphinium "Persimmon" was a prominent subject in a tall epergne. The new pink-flowered Astilbe (Spiræa) japonica, Iris hispanica in variety, Lilium rubellum, Gerbera Jamesonii, Watsonia Ardernei, Hencheras, Poppies were included.

Messrs. GEO. BUNYARD & Co., LTD., Maidstone, had a large exhibit of hardy herbaceous flowers, including Pæonies, Pyrethrums, Irises, &c., and a prettily-arranged rock garden, in which we noticed Spiræas, also Irises, Nymphæas, Dianthus in variety, Campanulas, &c.

Messrs. W. & J. BROWN, Stamford, staged a collection of greenhouse flowers, such as Fuchsias, Heliotrope Lord Roberts, &c.

Messrs. KELWAY & SON, Langport, Som., exhibited a collection of their noted strains of Pæonies, Pyrethrums, and Delphiniums.

Mr. JOHN FORBES, Hawick, exhibited a collection of Pentstemons of a fine strain, including the varieties Crimson Gem, Mrs. Callendar, Marconi, John Michie, also many good forms of garden Phlox, amongst them Duchess of Roxburghe, Madame G. Marie (white and of exceedingly large size), and Aviation, in colour salmon-pink. He also showed Violas and Pansies, and Pelargonium Black Vesuvius.

Messrs. WEBB & SONS, Wordsley, Stourbridge, staged a collection of Gloxinias of their noted strain, relieved with a background of Liliums and Kentia Palms. In the foreground they exhibited Cucumbers, Melons and Tomatos.

Messrs. R. H. BATH, LTD., Wisbech, exhibited a fine collection of Pæonies, amongst which we noted such beautiful varieties as Fiancée (white, of large size), Her Grace, Amazone (white with crimson tips), Hypatia, and others, all giving evidence of first-class culture.

A good collection of Caladiums came from Messrs. JOHN PEED & SON, West Norwood, S.E.

Messrs. HUGH LOW & Co., Bush Hill Park Nurseries, Middlesex, filled a large table space with Orchids, including Cattleya Mendelii, Cypripedium Schröderæ, Lælia tenebrosa, and choice forms of Odontoglossum crispum, also Bush and Rambler Roses, including Baby Rambler and Baby Dorothy, hardy greenhouse plants and Carnations.

Messrs. REAMSBOTTOM & Co., Alderborough Nurseries, Geashill, King's Co., Ireland, exhibited a collection of Anemones.

Messrs. JARMAN & Co., Chard, showed Centureas, Pelargoniums, and Carnations.

Mr. C. W. BREADMORE, Deanland Nursery, Balcombe, Winchester, had an array of Sweet Peas.

Mr. C. F. WATERS showed Carnations, some of which were of the Souvenir de la Malmaison type.

Messrs. E. J. BATCHELOR & SONS, Station Square, Harrogate, staged varieties of Nephrolepis exaltata.

Mr. H. N. ELLISON, 5 & 7, Bull Street, West Bromwich, showed Ferns in pots.

Messrs. WM. ARTINDALE & SON, Nether Green, Sheffield, displayed Violas and Pansies.

Messrs. SUTTON & SONS, Reading, displayed a collection of Melons in about 20 varieties, a number of Tomatos, all well selected fruits, 15 varieties of early culinary Peas, with many Cucumbers, including very large berries of Sutton's A1 variety. The exhibit was pleasingly arranged, a centrepiece being formed of Streptocarpus of a good strain, with Palms at the back and a number of small Ferns, vases of Sweet Peas, &c., interspersed.

Messrs. LAXTON BROS., Bedford, staged Strawberries, also Early Rivers' Nectarine, Hale's Early, Early Alexander Peaches.

AWARDS OF MERIT.

Marguerite Pink Queen Alexandra.—A sport from the double-flowered Queen Alexandra variety, having a pink tinting in the disc florets. Shown by Messrs. R. P. KER & SONS, Liverpool.

Nepenthes × excelsa.—A hybrid raised from N. Veitchii × N. sanguinea. The pitchers possess the reddish colouring of the last-named parent, the rim, which is remarkably handsome, being of a mahogany red colour. The plant is a robust grower: the young specimen exhibited had half a dozen pitchers, the largest of which measured 12 inches or thereabouts in length. Shown by Messrs. JAMES VEITCH & SONS, LTD., Chelsea.

HONORARY AWARDS.

The GOLD JUBILEE MEDAL offered for the best exhibit in the show was awarded to James Backhouse & Son, Ltd., for their rock-garden exhibit.

GOLD MEDALS.—Lieut.-Col. Holford, Messrs. James Veitch & Sons, Ltd., Wm. Cutbush & Son, James Backhouse & Son, Ltd.

AWARDS MADE BY THE ROYAL HORTICULTURAL SOCIETY.

GOLD MEDAL.—Mr. J. Coulthurst.

SILVER CUPS.—Messrs. James Pickersgill, Joe S. Sharp, James Blacker, George Prince, James Cypher & Sons, the Duke of Portland, the Earl of Harrington, R. Smith & Co., Ltd., R. H. Bath, Ltd., Geo. Bunyard & Co., Ltd., Hugh Low & Co., Kelway & Sons, R. P. Ker & Sons, Dicksons, Ltd., Artindale & Son.

HOGG MEDAL.—Messrs. Laxton Bros.

SILVER BANKSIAN MEDAL.—Messrs. Batchelor & Son, J. E. Skaife.

SILVER-GILT FLORA MEDALS.—Messrs. John Peed & Sons, W. Vause, J. Wood, W. & J. Brown, George Mount, W. P. Burkinshaw, J. Moore, Ltd., G. Gibson & Co., Harkness & Son.

SILVER-GILT KNIGHTIAN MEDAL.—Messrs. Sutton & Sons.

SILVER FLORA MEDALS.—Mr. John Forbes, C. W. Breadmore, W. Kettlewell, W. F. Crowther, Kent & Brydon.

GOLD VEITCH MEMORIAL MEDAL to Lt.-Col. Holford (gr. Mr. Alexander).

BRONZE VEITCH MEMORIAL MEDAL to W. P. Burkinshaw, Esq. (gr. Mr. J. T. Barker).

BIRMINGHAM BOTANICAL AND HORTICULTURAL.

JUNE 11.—The first of two special summer flower shows arranged to be held at the Birmingham Botanical Gardens, Edgbaston, during the present year, was held on the above date. Orchids, Roses, and hardy cut flowers were well shown. The weather was cool but fine, and the show was well supported by visitors. Eight medals were awarded to groups of plants and cut flowers, and one Award of Merit was given to an Odontoglossum.

ORCHIDS.

The Right Hon. JOSEPH CHAMBERLAIN, M.P., Highbury, Birmingham (gr. Mr. J. Mackay), sent a well-arranged group of superbly-grown Orchids, consisting principally of Cattleyas, Lælio-Cattleyas, Miltonias, and Odontoglossums. In the centre of the group was a grand lot of Odontoglossums in variety, and on either side of these Cattleya Mossiæ and Miltonia vexillaria were displayed in batches. Several forms of Lælio-Cattleya Canhamiana were of outstanding merit, and Cochlioda Noezliana was represented by seven well-flowered specimens. Phalænopsis amabilis Rimestadtiana, Masdevallia Harryana, M. ignea, Aerides Lobbi, A. affine superbum, Anguloa eburnea, and A. uniflora splendens were also included. (Silver-Gilt Medal.)

W. WATERS BUTLER, Esq., Southfield, Norfolk Road, Edgbaston (gr. Mr. R. H. Jones), occupied a table 30 feet long by 6 feet wide with a rich collection of Orchids, in which were good examples of Odontoglossum crispum, Oakwoodiense, O. c. gloria, O. citrosmum and its variety punctatum, Cypripedium Cassandra, Westfield var., C. hirsutissimum, C. bellatulum Wellesleyanum, and C. barbatum Rex. Cattleya Mossiæ, C. Vulcan, many choice Lælio-Cattleyas, Phalænopsis amabilis Rimestadtiana, Dendrobiums, Thunia Marshalliana, and T. Winniana. A number of plants of white Liliums were much admired at the back of this very fine exhibit. (Silver-Gilt Medal.)

Messrs. SANDER & SONS, St. Albans, sent a group of Orchids, in which was a remarkably good form of Lælio-Cattleya Canhamiana, with very large, richly-coloured flowers. Two other forms of L.-C. Canhamiana, namely, Marguerite and Rex, were noteworthy. Renanthera Imschootiana, with many flowers; Oncidium ampliatum majus, Odontoglossums, Cattleyas, Lælia purpurata alba, and Lycaste lanipes were shown in excellent condition. (Silver Medal.)

R. FENWICK, Esq., Edgbaston, contributed a small group of Orchids, mostly Odontoglossums. (Vote of Thanks.)

MISCELLANEOUS PLANTS AND CUT FLOWERS.

Messrs. BAKER'S, Codsall, Wolverhampton, staged a choice collection of long-spurred Aquilegias and varieties of large, showy Oriental Poppies. (Silver-Gilt Medal.)

Messrs. ROBERT SYDENHAM, LTD., Tenby Street, Birmingham, sent a beautiful collection of 20 varieties of Spanish Irises, together with the same number of varieties of South African Ixias. (Silver Medal.)

Messrs. GUNN & SONS, Olton, Birmingham, were represented by Roses in pots arranged in a semi-circular group on the floor. Teas, Hybrid Teas, Hybrid Perpetuals, Weeping and Pillar varieties were splendidly shown. Some of the best varieties were Madame Abel Chatenay, Richmond, Madame Falcot, Paul Transon, Lady Gay, Queen Alexandra, and Blush Rambler. (Silver Medal.)

Mr. H. ELLISON, West Bromwich, showed a collection of Ferns. (Bronze Medal.)

From Messrs. RICHARD SMITH & CO., Worcester, came a display of Pæonies, Pyrethrums, Campanulas, Heucheras, Irises, Incarvillea Delavayi, &c. (Bronze Medal.)

AWARD OF MERIT.

Odontoglossum crispum, Southfield var., from W. WATERS BUTLER, Esq., Edgbaston (gr. Mr. R. H. Jones). A very fine white flower, 4¼ inches across, the sepals suffused with purple, and spotted with chocolate brown.

COMPETITIVE CLASSES.

In a class provided for six Orchids in flower, dissimilar, the Right Hon. JOSEPH CHAMBERLAIN, M.P., Highbury (gr. Mr. J. Mackay), was awarded 1st prize. The three best specimens were Lælio-Cattleya Aphrodite, having four spikes and 13 large flowers, Miltonia vexillaria covered with shapely flowers, and Cattleya Mossiæ.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

JUNE 15.—The monthly meeting of this Society was held on the above date at the Horticultural Hall, Vincent Square, S.W., Mr. C. H. Curtis in the chair. Four new members were elected. The amount of sick pay was, since the last meeting, £35 8s. A member over 70 years of age was put on the benevolent fund, subject to rule 19, clause 3. The Committee hope that members will do all they can to induce young gardeners to join the Society.

THE WEATHER.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending June 13, is furnished from the Meteorological Office:—

GENERAL REMARKS.

The *weather* was generally fine over the greater part of England although slight rain was experienced in most places. In the north west of England, and in most parts of Ireland and Scotland falls of rain were rather frequent, and the general state of the sky was more cloudy. Thunder was heard at Dover on Monday evening, and at Stonyhurst on Thursday. On Sunday night "mock moons" were observed at Raunds.

The *temperature* was below the average, the defect varying between 2° and 3° in some of the northern and north-western districts. The highest of the maxima were registered at most stations on the 9th or 10th, and ranged from 74° or 75° over the south-eastern half of England to 66° in Ireland N., 65° in the English Channel, and to 64° in Scotland N. At several stations in the north and north-west the maxima were frequently below 60°. The lowest of the minima occurred on the 7th over the major portion of Great Britain, but on the 12th in nearly all parts of Ireland. In the English Channel the lowest value was only 46°, but in all other districts the thermometer sank to below 40°, in England S.E. and Scotland E. to 34°, and in England S.W. to 33°. The lowest grass minima reported were 25° at Llangammarch Wells, 27° at Crathes, 29° at Balmoral, Cockle Park, Morpeth, and 30° or 31° at Marchmont, Rauceby, Hillington, Cambridge, Wisley, Newton Rigg and Markree.

The *mean temperature of the sea.*—Except on some parts of the north-western and extreme northern coasts the water was warmer than during the corresponding week of last year. The actual values ranged from 60·6° at Margate, 57·0° at Eastbourne, and 56·0° at Newquay and Seafield to 50·1° at Aberdeen, and to about 47·5° at Wick and Lerwick.

THE WEATHER IN WEST HERTS.

Week ending June 17.

A moderate but welcome rain.—This was on the whole a cold week for the time of year. On three days the highest temperature in the thermometer screen did not rise above 60°, and on one night the exposed thermometer registered a reading within 1° of the freezing-point. The ground is now at about an average temperature at 2 feet deep, but 2° colder than is seasonable at 1 foot deep. Rain fell on four days, but to the total depth of less than half an inch. After a fortnight of dry weather the gentle but persistent rain which fell throughout the whole of last night was very welcome. On that occasion 1½ gallons was deposited on each square yard of surface in my garden. Considering the moderate quantity which fell it has already had a most beneficial effect on vegetation generally. This fall has not been sufficient to affect the percolation gauges, through which no measurable quantity of rain-water has passed for nearly a fortnight. The sun shone on an average for 5¼ hours a day, which is half an hour a day short of the average duration in June. Light airs, as a rule, prevailed during the week, but on one day the mean velocity for the windiest hour reached 13 miles—direction west. The mean amount of moisture in the air at 3 o'clock in the afternoon exceeded a seasonable quantity for that hour by as much as 10 per cent. *E. M., Berkhamsted, June 17, 1908.*

TRADE NOTICES.

WE are informed that the business of John Laing & Sons, Seed, Plant and Bulb Merchants, Forest Hill, S.E., has been transferred from Mr. David T. Russell to Mr. W. H. Russell (trading as John Russell), as, and from the 25th of May, 1908.

E. WRIGHT & CO., LTD.

THE above-named company has been registered with a capital of £6,000, in £1 shares (1,500 preference). Objects: To acquire the business of a manufacturer of a plant mildew destroyer (known as Mo-Effic Mildew Destroyer) and the business of a chemical manure merchant carried on by E. Wright, at 55, Brook Street, Bradford, as the Mo-Effic Chemical Co., Ltd., and E. Wright & Co., and to carry on the said business and that of manufacturers of artificial manures, fungicides, insecticides, fumigators, garden syringes and horticultural implements, &c. No initial public issue. Registered office, 55, Brook Street, Bradford.

MARKETS.

COVENT GARDEN, June 17.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—ED.]

REMARKS.—The trade for new Potatos is fair, but there is little demand now for old tubers. Jersey Potatos are showing traces of disease. English early crops are looking exceedingly well. *E. J. Newbon, June 17, 1908.*

COVENT GARDEN FLOWER MARKET.

During the past week all salesmen have complained of bad trade; yet I find that some have cleared out fairly well, and it is not safe to depend on the market for any special subjects. At the end of the season there are always some things which may be bought below market value, while it is very difficult to procure special subjects at the highest prices. Country buyers must never rely on what is reported as being in the markets one day, for it may be that it is the last of a large batch and the grower has none left.

CUT FLOWERS.

Supplies of choice flowers are very uncertain. Liliums vary from day to day: what may be bought one morning at 2s. per bunch may make 4s. per bunch a day or two later. The supplies during the last few days have been more than equal to all demands, and prices have been low, that is at the close of the market. It is the same with Carnations: those who have to buy for orders have to pay a reasonable price, but the surplus is cleared out at any price that can be obtained. Just now hardy flowers are a great feature. Poppies, Pyrethrums, Pæonies, and Gladioli being very prominent. Spanish Irises are also seen in large quantities, with these there is a very great difference in the prices: some are sold at 1s. 6d. to 2s. per dozen bunches, while others make from 6s. to 9s. per dozen bunches.

POT PLANTS.

Growers who have a surplus now clear out at low prices. The supplies of Zonal and also of Ivy-leaved Pelargoniums and Fuchsias are excessive. Of Marguerites, &c., there are now good yellow flowered plants, but since the yellow variety of Chrysanthemum coronarium has been so extensively grown, they do not sell so readily. Hydrangeas are still plentiful and good. Verbenas have not been making such good prices this season. Rhodanthe fetched but very low prices during the past few years and now it is difficult to obtain really well-grown plants. Mignonette is very good from all growers, but the autumn crop with the large flower heads is nearly exhausted.

There is not quite such a variety of foliage plants as we usually see at this season of the year, but cut foliage seems to have taken the place of plants to a large extent. Palms are in demand, also Ferns, but Crotons, Ficus and other coloured foliage plants are less in demand than formerly. *A. H., Covent Garden, Wednesday, June 17, 1908.*

ANSWERS TO CORRESPONDENTS.

*** *A report of the Royal Botanic Society's Show is held over until the next issue.*

A GARDENER'S TRAINING: *Father.* You state that the boy is a little defective in hearing and is no student or scholar, but is fairly apt at practical work and is willing and steady. We do not consider that he is calculated to become a first-rate gardener. In order to do this he should have received a good education and should be disposed to a considerable amount of study, but possessing sufficient intelligence to estimate the experience gained in practical work at its correct value. As a rule a young gardener should stay at least three years at his first place, but afterwards provided he can make a shift every twelve months into gardens that are well equipped and properly managed, he will gain by the varied experience thereby obtained. You state that you hope when the boy has attained the age of 21 years you will be able to start him in business with a capital of £100. We do not know what particular branch of the business you mean, but such a sum appears to us inadequate for any purpose except perhaps that of commencing a small market garden for the culture of outdoor crops.

APPLE BLOSSOM: *W. M. G.* There is nothing very remarkable in the blossom you send. Some of the stamens have become petaloid, and this duplication of the petals has resulted in a double flower.

APPLE TREE: *A. K., Dundee.* There are so many circumstances that may tend to make a tree unfruitful that it is impossible for us to give a definite opinion in your case without knowing something of the conditions under which the tree is cultivated. You have not even told us what variety of Apple it is. In these circumstances all we can do is to advise you to examine the roots next October or November, and if any are found that are growing directly down into the subsoil, cut these off, taking the opportunity to shorten most of the other roots which show considerable strength in order to induce the formation of root fibres, which are more valuable than thick roots.

CALANTHE LEAVES SPOTTED: *Constant.* The growth of Calanthe sent appears to be perfectly healthy. The small spots may have been caused by insects when the leaves were in course of development.

CARNATIONS: *D. I. D.* We are unable to help you in respect to the Carnations unless you can send specimens for examination.

LILIUM CANDIDUM: *D. W.* The plants are affected with the common Lily disease (Botrytis cinerea). Your best plan will be to burn the affected bulbs, and, after procuring fresh stock from an uncontaminated source, plant them in a fresh situation as far from the old site as circumstances will permit. The fresh plants may be sprayed very early in spring with a weak solution of potassium sulphide, or dusted with flowers of sulphur as a preventive. A suitable book is *The Book of Garden Pests and Plant Diseases*, by R. Hooper Pearson; it may be obtained from our publishing department.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. *Correspondents not answered in one issue are requested to be so good as to consult the following numbers.*

PLANTS: *A. B. H.* 1, Veronica Teucrium var. dubia nana; 2, Veronica Teucrium var. dubia; 3, Oxalis corniculata; 4, Castilleja miniata: 5, Aceras anthropophora.—*A. N. T.* Aira caryophyllea. — *E. C.* Momordica balsamina, a native of East Indies.—*G. C.* Spiræa species, but the specimen is too withered for accurate determination.—*E. H.* 1, Mertensia virginica; 2, Eupatorium petiolare.—*G. G.* The plant is commonly known in gardens as Zygopetalum intermedium.—*Foreman.* 1, Cochlioda rosea; 2, Aerides odoratum; 3, Ada aurantiaca: 4, Stanhopea oculata; 5, Catasetum macrocarpum.—*P.* Liparis Bowkeri.—*W. F.* Hæmanthus multiflorus.—*W. H.* Odontoglossum crispum of the guttatum section, but for which we know of no definite varietal name. The class, however, is tolerably common.—*Vitis.* 1, Anthericum liliastrum major; 2, Helianthemum vulgare, garden variety; 3, Cypripedium spectabile; 4, Astrantia major. The other two specimens being withered are not recognisable. —*J. C. Gould.* Rhaphiolepis ovata.

OLD PLANT OF ERICA: *Erica.* It is too late to disturb your plant now, but you can reduce the risk of losing it if you loosen the soil with a fork and give a dressing of peat in order to encourage additional surface roots. The soil should be kept moist all through the summer, and the specimen lifted with as good a ball of earth as possible towards the end of March or early in April next year.

PTERIS FERN: *H. Reynolds.* There is no disease present in the fronds. The browning may be due to burning by the sun's rays, to excessive transpiration owing to a dry, heated atmosphere, or even to manure water having been shed over portions of the plants.

TOMATO DISEASE: *A. B.* You do not state which disease is attacking your Tomato plants, but we suspect it is Cladosporium fulvum. Spray the plants with the Bordeaux mixture at ordinary strength and admit plenty of ventilation to the structure in which they are growing.

TOMATOS: *H. N. H.* We should regard boggy land as being most unfavourable for erecting houses for the cultivation of Tomatos. These plants require to be grown in moderately dry conditions, such as are generally most prevalent on high land where fogs or mists are infrequent. But if you have no other choice you must make the houses damp-proof as far as possible, and by a proper use of fire-heat, accompanied by ventilation during favourable weather, endeavour to bring about atmospheric conditions in the houses which are opposite to those prevailing out of doors.

MARKET STRAWBERRIES.

WHEN Strawberries of the best quality can be bought within a day or two of the middle of June at the retail price of fourpence and fivepence a pound, one begins to wonder whether the industry, which has now assumed such huge proportions, is not being overdone. Until Hampshire began sending Strawberries to London and other large towns, there was not much fear that the demand would fall below the supply, but during the last few years there have been indications that acres of Strawberries are increasing too rapidly for the population, and growers have been grumbling for some time past about unremunerative prices. Strawberries can be grown, of course, to sell retail at fourpence, and even threepence per pound, and still leave a fair profit for grower and retailer, but when, within a week of the crop appearing on the market, prices drop from one and sixpence and a shilling per pound to about a third of those sums, it shows that the market is being very heavily loaded and can hardly cope with the supply.

There is one reason why Strawberries, when they are plentiful, do not bring the prices that the grower had hoped to obtain, and it has to do with the way in which they are marketed. The Kentish grower still persists in using the clumsy peck basket, which is fit enough for marketing such hard subjects as Peas or Potatos, but is entirely unsuitable for a fragile fruit like the Strawberry. Even the gallon basket, as used by the Hampshire growers, is really too large when Strawberries are fully ripe, although it would be difficult to devise a style of package better than the handle-basket with which everyone is so familiar. If, however, four pounds of fruit were the limit for each package, it would be much better for everyone, and the fruit, being more attractive and in better condition, would realise a better price, besides stimulating a demand that can never arise for ill-conditioned berries. It is mere folly, when fruit gets squashed, even in a five-pound basket, to cram 12 pounds of it into a peck measure, but this is what the Kent and Sussex grower has been doing for years past and is still doing.

Another matter to which the fruit-grower ought to pay more attention is the grading of his fruit, but so far he has not profited by the example of the French, the Canadians, the Americans, and the Australians. Certainly, the home grower of Strawberries does at times send into the market what he calls "seconds," but this is usually when all his best fruit is gone and he has nothing to top up with! The extent to which "topping up" is still practised is absurd, and there is nothing which makes the British purchaser so unwilling to pay a good price. The writer has examined scores of baskets from the Southampton district this season, and in nearly every one of them there was a large proportion of berries which ought never to have found their way into a basket of first-grade fruit. This grading is admittedly a difficult matter and would necessitate the carrying by the picker of two baskets—one for the best fruit and the other for the "seconds"—but it ought to be quite as easy to put small and badly-shaped berries into a separate basket as to collect them carefully for filling up the space beneath the larger and better berries. Most of the French Strawberries which arrive in London are even in size and quality, and as a rule they have the appearance of having been just gathered from the bed. Yet they have received more handling than the English fruit and have travelled a far greater distance. These results are due, of course, to smaller packages, careful packing, and strict grading.

It is a little curious that Strawberries should have dropped in price so soon this year and thereby have curtailed the period when the grower reaps the richest portion of his harvest—when we recollect that the first consignments on the market were earlier than usual. This year the first of the Southampton berries, whose arrival may be said to mark the beginning of the season proper, appeared in London on June 10, and the first "Strawberry Special," carrying some 12,000 pounds of fruit, arrived early on June 12. Another train, with 8,000 pounds on board, arrived during the day. Last year the first of the Southampton crop did not reach London till June 13, but that was some five or six days earlier than 1906. Every year, in fact, the season gets a little earlier, owing, no doubt, to the improvement of varieties. At the same time, if we may judge by the returns of 1907, the season also lengthens at the other end—a fact doubtless due to the growing of late varieties. It is quite within the bounds of possibility that, before many more years are past, the Strawberry season will last from the beginning of June till the end of July.

Most people will be surprised to learn that last year was the best Strawberry season on record. Previously to that, the greatest crop in the Southampton district was that of 1904, when some 4,250 tons of fruit were carried by train in nearly 2,000,000 baskets. Last year, however, the London and South-Western Railway Company handled 2,100,148 baskets of Strawberries, aggregating a total weight of 4,705 tons. Swanwick, which is the chief centre of the industry, contributed more than half this gigantic total, the rest coming chiefly from Bursledon, Botley, Wickham, and Sholing. On the average, during the height of the season eight special trains are required to convey the fruit to London, Liverpool, Manchester, and other big towns. Some of it also goes to Scotland, and a few vanloads to Ireland. At the same time ordinary passenger trains take small consignments to every town, large and small, in Hampshire and the adjoining counties, besides which several tons are carried by road to Southampton and other places in the district.

The figures for this year's crop will not be available until August or September, but it is fairly certain that, with the continuance of fair weather to the end of the season, the crop will be as big or bigger than that of a year ago. But it is likely that, in view of the low prices now obtaining, a much larger proportion of fruit than usual will be made into jam. The jam-makers' prices are low, but when one takes into consideration the fact that he is not so particular as to quality and will come and fetch the fruit in his own vans, it is evident that the grower may sometimes obtain a better result by dealing with him than by sending his fruit to market for dessert. *East Sussex.*

NOTES FROM ISLEWORTH.

FRUIT PROSPECTS.

THIS season is one of extraordinary promise in the orchard, and most fruit trees will demand thinning if sizeable fruit is to result. Apples are generally carrying two or three times as many fruits as the trees should be allowed to bear, and Plums are also heavily overburdened. Pears are a full crop generally. Apricots and Sweet Cherries are failures in this garden. Peaches and Nectarines are nearly an average crop.

On the wall trees the set of fruit is also good; Apricots are thin and variable, owing to the tremendous crop of 1907, but Morellos are a good crop. I have taken the following notes as to some kinds of orchard-grown fruit, averaging out the results. The figure 100 represents the maximum crop that should be left on the trees after thinning, so that the figure 70 may be taken as representative of an average crop over a series of years:—

APPLES.—Cooking sorts (early) 300, cooking sorts (late) 250 (Lane's Prince Albert 350).

Dessert sorts (early) 150 (Irish Peach 200); dessert sorts (later) 220 (Cox's Orange Pippin 150, Ribston Pippin 300).

Various edible and fancy Apples 110 (Celini Pippin 50).

PEARS.—Best dessert sorts 80 (Marie Louise 55, Doyenne du Comice 150, Beurré Bosc 125, Louise Bonne of Jersey 10, Chaumontelle 70); latest dessert sorts 150; various dessert sorts 90 (Jargonelle 60).

Stewing Pears 25.

PLUMS.—Cooking sorts 200 (Victoria 400); Damsons 30.

Best dessert sorts 85 (Reine Claude de Bavay 100, Coe's Golden Drop 40); various dessert sorts 70 (Jefferson 40).

Japanese sorts are a complete failure.

Small fruits promise well, especially Strawberries and Black Currants, but Red Currants are variable, and Gooseberries a failure in most places. In exposed situations the crops will not be quite so good. *A. Worsley.*

ORCHID NOTES AND GLEANINGS.

CYPRIPEDIUM VENTRICOSUM ALBUM.

At the recent Temple Show Messrs. Wm. Cutbush & Son, Highgate Nurseries, London, exhibited a fine batch of a beautiful rose-coloured Cypripedium as C. ventricosum, and the Orchid Committee awarded it a First-Class Certificate. In the group was a clear white variety, an illustration of which, on a reduced scale, is now given at fig. 183. The plant shown by Messrs. Cutbush is identical with that figured in Reichenbach's *Icones Floræ Germanicæ* as C. ventricosum, but in the letterpress is referred to as C. macranthos var. ventricosum, and there is no doubt that it has been cultivated as C. ventricosum, under which name Messrs. Cutbush imported it.

Some 20 or 30 years ago what was regarded as true C. macranthum was tolerably plentiful in gardens, and a coloured plate of it, taken from a specimen supplied by Messrs Backhouse, of York, together with a note by the late Mr. Burbidge, was given in *The Garden*, January 13, 1877. It is very doubtful whether the plants there illustrated now exist in gardens, and no one who knows C. macranthum as shown in *The Garden* figure could consider it the same species as the C. ventricosum shown by Messrs. Cutbush.

The original descriptions, with their stress on the size and relative length of the lip and the petals, and the form of the staminode, do not help, for those who have grown these Cypripediums know that these features vary as the flowers mature, and the relative proportions might depend on the age of the bloom being described. A good deal of confusion among herbarium specimens also seems to have been brought about by similar variation in the plants dried. From the same cause, the figures, too, are rendered unreliable in like manner, a marked instance of it being what is called typical C. macranthum and the plate of C. ventricosum in *Icones Floræ Germanicæ*, both of which might have been taken from the same plant, the former being much the smaller and evidently a freshly-opened flower. A marked feature in the C. macranthum referred to as being cultivated by Messrs. Backhouse and others 30 years ago is that the infolded sides of the labellum were coloured, whereas in the plant known as C. ventricosum they are white. The colour of the former is also different, although not so red, but more purple tinted than shown in the figure in *The Garden*.

With regard to their C. ventricosum, Messrs. Cutbust write:—"There is a difference in the root-stock, C. macranthum having a fine, fibrous root, whilst C. ventricosum has a fleshy root, the difference being most apparent. We have now pure white forms of C. macranthum, and also several brownish types, which, we think, proves that the species hybridise between each other in nature."

It is a native of Siberia, but appears to be cultivated extensively in Japan.

HARDY PLANTS AT HAYES COMMON.

In visiting Mr. Martin R. Smith's garden at Hayes, one expects to see Carnations in great numbers. But I was not prepared to find such a very ample collection of Alpine and other early hardy flowers as are cultivated there, many in a house especially set apart for them. Not only was this house at the time of my visit gay with flowers, but there was also in the open a very considerable number of choice plants whose flowering period had either passed or had yet to come. The house in which the plants are grown is a span-roofed structure, with ample side and top ventilation, much resembling the Alpine house at Kew in these respects, which is without doubt the best type for the purpose. The staging is on a level with the opening lights at the sides, and in this way the plants receive plenty of fresh air. The culture of Alpines and other hardy flowers under glass is a comparatively new feature at Hayes, and when this fact is remembered, the condition of the large and varied collection merits praise. At the time of my visit many species and varieties of Primulas were in bloom, including P. Veitchii, P. pulverulenta, P. frondosa, P. Cockburniana, P. Kewensis, P. Fisheri, P. verticillata, P. obconica in variety, P. japonica, and P. Sieboldii in variety. P. suffrutescens, a Californian species with reddish flowers, was also noted in quantity, and obviously flourishing, and there were many other species and varieties, such as P. viscosa, P. pubescens alba, P. Stuartii, &c., most of which were in flower at the time of my visit. Many of the choicer Saxifragas, too, are grown, the collection including S. Burseriana, S. lantoscana, S. squarrosa, S. cæsia, S. valdensis, and others of the encrusted type, with

FIG. 183.—CYPRIPEDIUM VENTRICOSUM, VAR. ALBA.

a representative gathering of the smaller-growing "mossy" kinds for variety. Of the Androsaces there were many choice examples. To state that such species as A. pyrenaica, A. arachnoidea, or A. argentea have white flowers, it may be with a yellow eye, or not, conveys but little idea of the dainty grace or charm of these denizens of Alpine regions, for the plants possess beauty in their miniature tufts of leaves crowned with their blossoms. Another species (A. Chumbyi) was gay with rosy-pink heads of blossoms, and the rare A. helvetica was also in bloom. Daphne arbuscula, a somewhat trailing species, with pink flowers in clustered heads, and the even more beautiful and rare D. tupestris (petræa) from the Tyrol were among the most beautiful plants in flower. The latter plant has rose-pink flowers of almost wax-like texture arranged in close heads on a 4-inch high tuft of leaves; the blossoms, too, are delightfully fragrant. Aubrietia, Fritillaria, Dianthus, Lithospermum, Gentiana verna and Houstonia are a few of the many other plants which add interest or beauty to such a gathering of early hardy flowers, and which assist in making this modern phase of gardening in cool or unheated structures one of the most fascinating and enjoyable. Obviously Mr. Martin Smith has entered upon the culture of hardy plants with enthusiasm, and in bringing it to its present state of excellence finds a willing helper in his gardener, Mr. Blick. *E. H. J.*

COLONIAL NOTE.

ENCEPHALARTOS WOODII.

In your issue of April 25, which has just reached me, I observe a short note on the plant of Encephalartos shown at Ghent by Messrs. Sander & Sons, and think that perhaps it may interest some readers of the *Gardeners' Chronicle* to learn the history of this plant so far as it is known to me.

In the year 1895 I was on a botanical collecting trip with wagon and oxen in Zululand, and having reached a spot where the country was very rough I stayed for several days botanising in the vicinity, and in so doing found a solitary clump of Encephalartos, consisting of four stems, the tallest of which was about 18 feet high, with proportionate girth of stem, and with a few offsets at base; the stems were all male, and not another plant of the species could be found in the vicinity, though we found a number of plants of E. brachyphyllus, of which we took away a number of specimens. Some years afterwards, our curator, Mr. J. Wylie, visited the locality, and I directed him to the place where these Encephalartos were. He brought back with him several of the smaller plants of the group, three of which were planted here, and in my report for 1906-7 I gave a photograph of one of them, with a very short note as to the habitat of the species. We have in the garden seven species of Encephalartos, and numerous specimens, but these three, as far as the foliage is concerned, are, in my opinion, not only the handsomest of all, but are strikingly different from any of the others, and I regret very much that such fine specimens as I saw should have been wantonly destroyed by the natives. I may conclude by saying that we have in the garden a plant, of which I believe there is a photograph in the museum at Kew. It has been known as the "Giant Encephalartos." This plant is a male, and this year has no less than 18 cones, arranged in more or fewer complete concentric circles. I think that this is a record number; the trunk has been partly buried in the side of an embankment, and it is intended to remove it to a position where its full length can be seen to better advantage. *J. Medley Wood, Director, Natal Botanic Gardens.*

ABNORMAL SEEDLINGS.

ACER PSEUDO-PLATANUS.

A seedling from Kew Gardens examined by me had one of the two cotyledons deeply bipartite. It is known that in some cases of the same kind, the first whorl of foliage leaves succeeding the cotyledonary whorl has either three members or one of the two leaves bifid, or partite; but this is not always the case. In the present instance a whorl of two foliage leaves occurs about a quarter of an inch above the insertion of the cotyledons. The remarkable point about this seedling, however, is that there is a *third* foliage-leaf situated at the extreme base of the first plumular internode, i.e., immediately above the cotyledons; it is much smaller in size than the two foliage-leaves higher up, is pitcher-shaped, and long-stalked. It apparently alternates on one side of the axis with the two cotyledons, and has displaced the whorl of foliage-leaves from its normal position in such a way that one

of these leaves appears to alternate with the two lobes of the bipartite cotyledon, and the other seems to be making an attempt to alternate with the two cotyledons on the side of the axis opposite to that on which the third foliage-leaf is situated. The most probable explanation of the latter is that it is the sole representative of a bud which is axillary to the undivided cotyledon, and, owing to the complete abortion of its own parent axis, it has become congenitally attached to the main plumular axis of the seedling. Its position on the latter, rather to one side of the median plane of the cotyledonary axil, might be explained by supposing it to be one of the first pair of transversely—not medianly—placed leaves of the axillary branch. No other hypothesis than the above will, I think, account for the presence of this third foliage-leaf. Its peculiar shape is probably the result of weakness of development, as is also seen in its diminutive size.

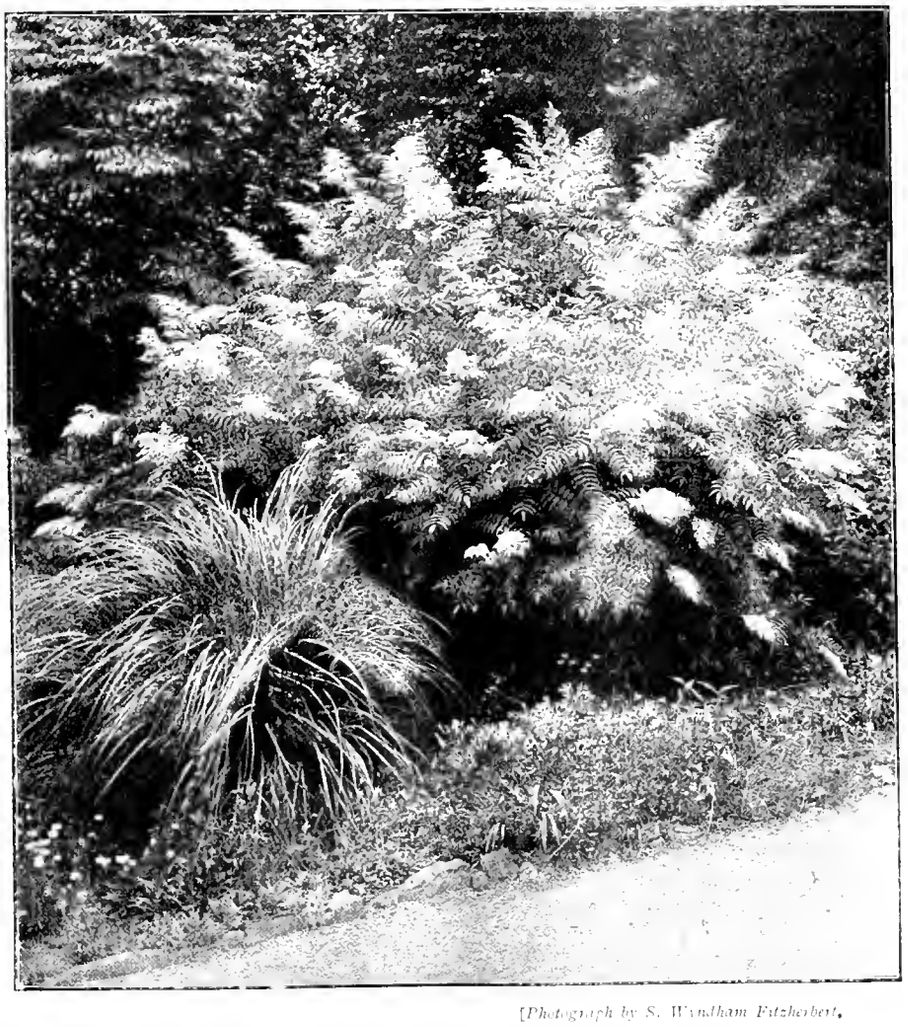
regarding the "double" seedling superficially, the impression obtained is that of a *single* seedling, which has two distinct radicles, which would be a sufficiently puzzling phenomenon. *W. C. W.*

TREES AND SHRUBS.

SHRUBBY SPIRÆAS.

(Concluded from page 397.)

SPIRÆA DOUGLASII.—Where favourably situated (for it is a great lover of moisture), this forms a mass of upright, reed-like stems, each of which is, in July, terminated by a dense, erect spike of bright rosy-red blossoms. When the main spikes have finished flowering, secondary shoots are often pushed out immediately below, thus extending the season of blooming till well on into the autumn. Spiræa Douglasii is a native of much the same region as the preceding species



[Photograph by S. Wyndham Fitzherbert.

FIG. 184.—SPIRÆA LINDLEYANA: FLOWERS WHITE.

EREMOSTACHYS LACINIATA.

AN example was seen of a double seedling, which seems to have arisen through an imperfect formation of twins. What has apparently happened is as follows.—The embryo, or rather, perhaps, the fertilised egg-cell, bifurcated above in one plane, and also below in a plane at right angles to this, and thus two radicles or primary roots were produced. As a result of the former process, viz., bipartition of the upper half of the embryo, we should expect that, in the developed seedling, four cotyledons would be produced; but this is not the case. There are only *two* cotyledons, but each is obviously a double one, and what has taken place is that, owing to lack of adequate space for the proper development of all four, the two cotyledons of each twin have become congenitally united to form a single "double" one. Hence,

SPIRÆA JAPONICA.—This has long been grown in gardens under the name of Spiræa callosa, but the first name is now accepted as the correct one. It is decidedly variable, some of the forms at one time or another having been regarded as distinct species. The type forms a rather upright bush, which in July is studded with flattened corymbs of rosy-red blossoms. A notable feature of this plant is the bright-crimson tint of the young leaves, particularly when grown in a spot fully exposed to the sun. The variety superba has flowers richer in colour than the common form. Of this Spiræa there is a group of dwarf-growing varieties, notably alba (white), Bumalda (pink) (see fig. 185), and Anthony Waterer (crimson).

SPIRÆA MEDIA, SYN. S. CONFUSA.—In gardens where hardy shrubs are forced into flower for the embellishment of the greenhouse or conservatory, this species is very generally met with, as it is a favourite for the purpose. Thus treated, the foliage is of a delightful shade of soft, glaucous-green, and the neat little bushes, thickly studded with clusters of pure white blossoms, are very beautiful. In the open it blooms late in the spring, but the growths are sometimes injured by frosts when the flower-buds are developing.

SPIRÆA PRIMIFOLIA FLORE PLENA.—The double flowers of this Spiræa form a markedly distinguishing feature. It is a loose-growing bush, 6 feet or more in height, the long wand-like shoots, about the latter part of April, being almost clothed with clusters of little white rosettes of flowers, whose purity is enhanced by the dark-coloured bark of the shoots. It is a native of China and Japan, and is one of the many good garden plants whose introduction we owe to the late Robert Fortune.

SPIRÆA SALICIFOLIA (see fig. 186).—A native of a considerable part of the northern portion of both hemispheres, this, as might be imagined from its wide geographical distribution, is a decidedly variable species. It forms a bush 6 feet high, and bears its flowers in spike-like panicles in the latter part of the summer. Some plants produce white flowers, others pinkish. The North American form, known as paniculata, is one of the best.

SPIRÆA THUNBERGII.—The earliest of all to unfold its blossoms, this is a neat twiggy bush, clothed during the summer with small, narrow leaves, that are borne in dense masses. The tiny white flowers remain expanded for some considerable time.

SPIRÆA LINDLEYANA (see fig. 184).—Although this plant and the nearly allied S. Aitchisonii are both members of the same section, the two species are so distinct from each other, and such valuable August-flowering shrubs, that a place should be found for both of them.

CULTURE OF SHRUBBY SPIRÆAS.—These shrubby species of Spiræas need liberal treatment, for when planted in an ordinary shrubbery they are often robbed of nourishment by their more vigorous neighbours. A good open loam forms the best rooting medium, and they are very impatient of drought at their roots. A liberal mulching of fairly rich manure is very helpful. Pruning is an important item, as plants are greatly benefited by the removal of old and exhausted wood, thus encouraging the development of young, vigorous shoots, on which flowers are produced. *W.*

The Week's Work.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Lt.-Col. G. L. HOLFORD, C.V.O., C.I.E., Westonbirt, Gloucestershire.

Vanda teres.—This species is one of the most desirable Orchids for flowering at the present season. The plants are decorative, especially when bearing strong flower-spikes, and their beautiful blossoms last a long time, provided the plants are placed in a warm, well ventilated, shady house, and kept moist at the root. Plants that have flowered freely usually shrivel a little, but they soon regain their plumpness when returned to the growing quarters. The work of repotting, or surfacing, should receive attention soon after the flowers have faded. It is a good practice to cultivate Vanda teres fastened to teak-wood stakes, to which the young clinging roots attach themselves readily. Tie each plant separately to a stake of sufficient length to allow for one or two season's growth. The plants can either be placed singly in pots, or a number may be put together to make up specimens. When the latter system is adopted, sufficient space should be afforded between the stems to allow admission of sunlight. The plants may be fixed firmly by packing in pieces of crock edge-ways, filling two-thirds of the pot with clean pot-sherds and charcoal, and the remainder with clean-chopped Sphagnum-moss. It is sometimes neces-

sary to reduce the height of the plants to suit the position they occupy in the house. This may be done by removing the lower portion of the stem, cutting away about 1½ feet and lowering the plants to that extent. If an increase of stock is desired, pot up the portions cut away, and these will soon grow if afforded plenty of heat and moisture. These Vandas should be accommodated in the warmest house, such as the ordinary plant stove, and during the summer months they require an abundance of moisture, both at the root and in the atmosphere. A position should be chosen for them where they can be fully exposed to the sun's rays, and on bright days be frequently syringed overhead.

Vanda Hookeriana and its hybrid, Miss Joaquim, may be grown under similar conditions.

Thunias.—Most of these plants will now have ceased flowering, and they should be removed to a house where they can have plenty of air and be exposed to the full sunshine, so that the stems may ripen. Later on when the stems have hardened a little, the plants may be placed outside, provided the weather is favourable. Continue to give water in abundance at the roots, and in order to keep the foliage free from thrips and red spider syringe the foliage freely twice daily until the leaves begin to fall.

PLANTS UNDER GLASS.

By THOMAS LUNT, Gardener to A. STIRLING, Esq., Keir, Perthshire, N.B.

Agathæa cœlestis.—A batch of two or three dozen examples of this flowering plant arranged with a similar number of Primula × Kewensis affords an excellent effect in January and February. Cuttings of the Agathæa may be inserted at the present time. Place four cuttings in each pot of a diameter of 3 inches, and containing a compost of loam, leaf-mould, and sand. The cuttings should be rooted in an intermediate temperature. They require to be shaded from sunshine, and the atmosphere should be kept close. Let the rooted cuttings grow and be hardened off in the same pots until they are fit for shifting into pots 6 inches in diameter, and in these the plants may be allowed to flower. If treated as Cinerarias until the end of September they will succeed. No flower buds should be allowed to develop before the end of September, and the growths should be pinched two or three times during the summer in order to promote a bushy habit. In October the plants should be removed to a cool greenhouse, placing them close to the roof glass. As soon as the flowers begin to open the roots may be given liquid manure.

Cyclamen.—Seedlings growing in pots should be examined and repotted if necessary, afterwards placing them in an unheated frame. Be very careful to ascertain if the plants are affected with green fly or thrips, and fumigate them directly these pests are observed, failing which they will disfigure the foliage. Plants that were planted out into a frame are now making fresh growth. They require the frame to be well ventilated, and they should be syringed twice daily in favourable weather. When the growth is well advanced, the lights may be removed altogether on warm nights, as the plants will be benefited by the dews. Replace the lights early in the morning, and if the sun is very bright afford the plants shade.

Souvenir de la Malmaison Carnations.—Old plants that have finished flowering, and are not required for cultivation another season, should be planted out in an unheated frame for the purpose of layering. By this system the plants are enabled to increase their vitality before the shoots have to be pegged down as layers, consequently the young plants show greater vigour than is the case with those obtained from cuttings rooted in pots. A compost of loam, leaf-soil, and sand is suitable for the planting of the specimens or for the layering of the shoots. Syringe the plants twice a day at this season of the year, and ventilate the frames freely. Directly the shoots have been layered the frames should be slightly shaded from sunshine and kept close for a week or so.

Azaleas. Plants that were forced early and have made their growth should now be planted out-of-doors on the bed of ashes, or, failing this, each pot should be stood upon a large-sized slate. Select a well-sheltered, sunny position. While the plants are out-of-doors they will need attention in the matter of root waterings.

THE FLOWER GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

Climbing Roses.—Take care that no injury is allowed to affect the young shoots coming from the base of the plants, as these will furnish the main portion of the supply of flowers next season. Many of them require the support of stakes. Longworth Rambler and Paul's Carmine Pillar, now flowering, are excellent Roses for furnishing pillars or arches, and should be noted by prospective planters. Frequent syringings will be valuable in keeping the foliage free from insect and other pests. Occasional applications of liquid manure may be made to the roots. Any plants that are growing in positions near to buildings will need more frequent root waterings than the plants in exposed positions.

Flower beds.—In order to encourage the plants to grow quickly, give frequent root waterings if the weather is dry, and keep the beds scrupulously free from weeds. The hoe should be used to loosen the surface soil as often as convenient.

Herbaceous plants.—Many of the herbaceous plants require staking or thinning out at this season, and the borders need to be weeded; seedlings that have been raised this season may require to be transplanted, and in the case of other species seeds now need to be sown. If such plants as Oriental Poppies, Doronicums, and Pyrethrums have the old leaves and stalks removed after flowering and given a good dressing of short manure, and water when necessary, they may be induced to flower again in autumn.

Anemones.—These plants seed so freely that it is only desirable to save seeds from the brightest and best flowers. These can be marked when in bloom. The seeds are very woolly and are not easily separated from each other, but it is necessary that this should be done; therefore mix them with fine sand or soil and rub them together. A very fine surface is needed for the reception of these seeds, and if sown out-of-doors they had better be sown in drills than broadcast, as the beds afterwards will be so much more easily weeded. Make the soil moderately firm, and if it is well drained, but kept moist by added water, the seedlings may be expected to appear in about three weeks. The roots of the more select varieties may be taken up when the leaves have withered, but they will be planted again in autumn.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree, Hertfordshire.

Runner Beans.—Attend to the staking of these plants immediately they begin to "run." There are few crops which yield a better return during summer and autumn, especially if the best varieties are grown and good culture afforded. One of the most important items essential to success is to provide the plants with long supports. These should be, except in very exposed places, at least from 8 to 10 feet in height. If the growths are stopped at this point and the plants allowed a sufficient distance to prevent overcrowding, they will continue to grow and to bear freely until frost puts an end to them in the autumn. Apply a good mulching immediately the staking is completed, and keep the roots well supplied with moisture. Those in earlier stages which were planted out from pots or boxes will soon be coming into flower, and to encourage a free and early set the growths should be syringed early every afternoon after hot days. Fortunately, few insect pests or diseases attack these plants, though black aphis sometimes causes trouble; these are easily and quickly destroyed by syringing with strong soft-soap and water.

FIG. 185.—SPIRÆA JAPONICA BUMALDA: FLOWERS PINK.

(For text see p. 415)

French Beans.—Those which are fruiting in cold frames should be liberally supplied with manure water and the foliage kept well syringed. If the variety is of the Canadian Wonder type, it will continue to bear freely until the plantations outside come into bearing.

Broad Windsor Beans.—Late sowings of Broad Windsor Beans should be heavily mulched and kept well supplied with water, or the yield will be poor. Stop the growths of mid-season sowings immediately a fair amount of bloom can be seen; the majority of the first flowers will fail to set if the shoots are not stopped. Those in full bearing should be liberally supplied with manure water, and if any special pods are required for exhibition or other purpose, these should be thinned somewhat severely, leaving the most promising.

Herbs.—Many of the varieties which are coming into bloom, unless required for cutting and drying purposes, should have their growths shortened back to ensure a plentiful supply of fresh, young shoots. Both annual and perennial kinds which were sown during the spring should now be thinned to a reasonable distance

to prevent overcrowding. Keep the crop free from weeds, and hoe the surface frequently.

Sorrel.—This is now very much in demand in many places, and to ensure a good crop of healthy young foliage the growths will need to be cut down occasionally to prevent them flowering. A good dressing of artificial manure should be given between the rows and well hoed in. Should the weather be dry, give a thorough watering.

Onions.—Early-sown transplanted crops are looking remarkably well this season in most places, and everything points towards seeing

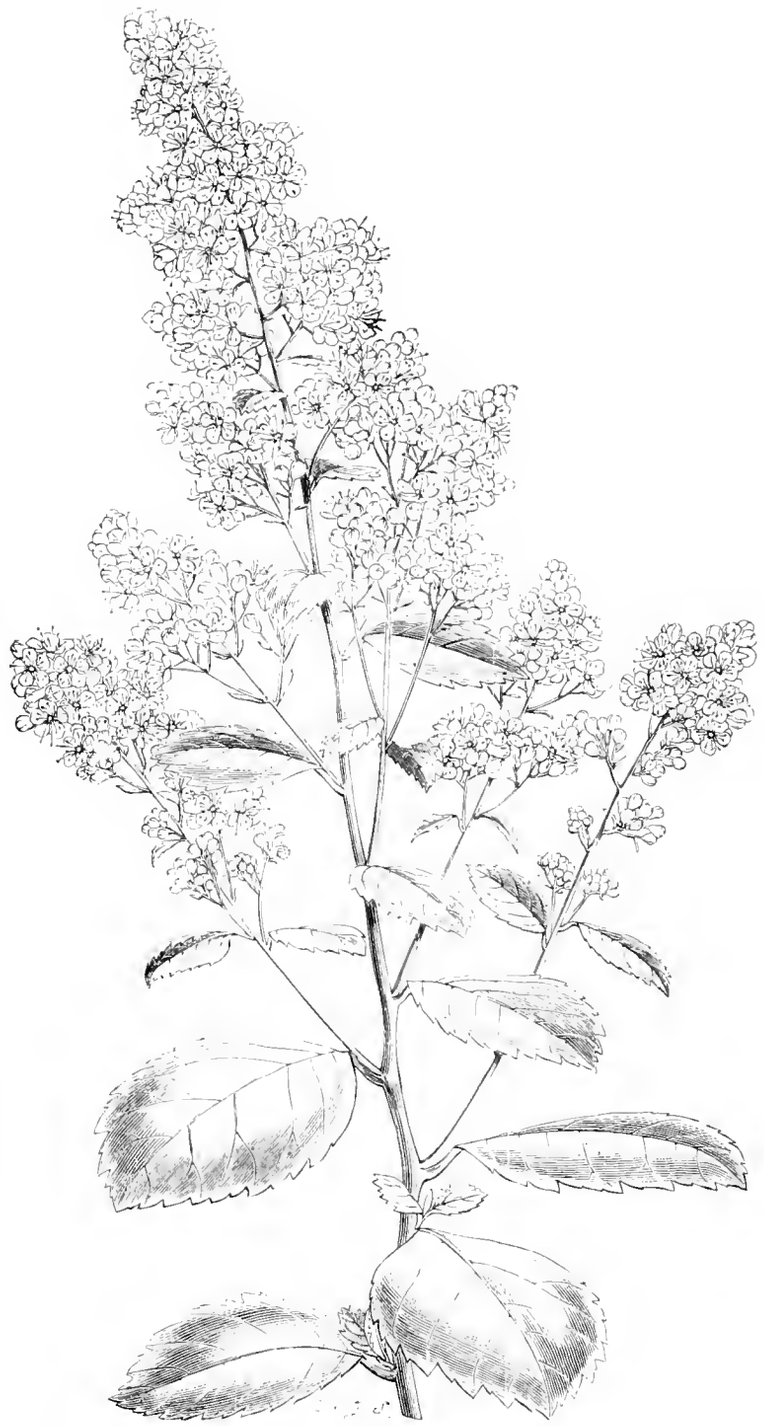


FIG. 186.—SPIRÆA SALICIFOLIA; FLOWERS PINK.

(For text see p. 415.)

these in very much better condition than has been the case for several seasons past. The plants will need judicious feeding and plenty of water for some time to come, but great care must be taken not to be too liberal in feeding, and especially in applying patent manures. Valuable as these are when properly applied, too many people often do not follow the directions given, the result being that more harm than good is done.

THE HARDY FRUIT GARDEN.

By F. JORDAN, Gardener to The DOWAGER LADY NUNBURNHOLME, Warter Priory, Yorkshire.

Insect pests.—Of the many items of work claiming attention during June and July, the combating of insect pests, including the numerous species of caterpillar, is one of the most important. It is almost impossible to save a crop of fruit when a tree has once become badly attacked by caterpillars, but at least the effort should be made by hand-picking and washing with insecticide to lessen their numbers that they may be less destructive another season. In bad cases where the crop is hopelessly ruined, and upon trees which are bearing no crop, the syringing may be done with Paris Green at the rate of 2 ounces to 30 gallons of water. This will quickly kill all insects upon the tree, and the liquid is quite safe to apply at this strength if the trees have already made considerable growth. Paris Green should only be applied with very great care upon trees bearing satisfactory fruit. It is not always possible to destroy the webs of caterpillars on large orchard trees, but a sharp look-out should be kept on smaller trees, such as pyramids and bush-trained specimens, while the operation of summer pruning is in progress, removing the webs carefully and casting them into a bucket containing some petroleum. Gather all fallen Apples and burn them, as they probably contain the caterpillars of the Codlin moth or other pest.

American blight.—Rub over any parts affected with American blight with a stiff brush dipped in methylated spirit, unless in cases where the trees are very badly affected, when they may be syringed, as recommended in a former Calendar.

Figs.—Fig trees should now be freely disbudded, to prevent the shoots becoming overcrowded and in order that the fruits may be fully exposed to the light and air. Remove the extra strong shoots and retain those that are short-jointed, as these latter will mature better and prove most fruitful. Trees growing in properly-constructed borders and carrying full crops of fruit require liberal waterings of liquid manure until the fruits show signs of ripening, when they must be discontinued, but do not apply manures of any sort to barren trees or specimens that are inclined to grow too strongly. Remove sucker growths from old trees and thin the fruits if necessary, but do not stop the shoots. Very little, if any, syringing is necessary for Figs out-of-doors.

Hoeing.—Use the hoe frequently in all the fruit quarters at this season, remembering that should the weather prove very dry, hoeings and mulchings have an excellent effect in conserving the moisture contained in the soil.

FRUITS UNDER GLASS.

By T. COOMBER, Gardener to LORD LLANGATTOCK, The Hendre, Monmouthshire.

The Orchard house.—Pot trees of Cherries Peaches, and Nectarines that are cleared of their fruits should be carefully watered, and have their foliage kept clean by daily syringings of clear water. The house should be kept freely ventilated at all times, and as soon as the shoots have become well hardened the trees may be placed in a warm, sheltered position out-of-doors. It will be an advantage if the pots are plunged in a bed of fine ashes. Later fruiting trees of the kinds named, also those of Plums, Pears, Apples, &c., that are swelling their fruits, should, if not been already done, be finally top-dressed with a mixture of loam, wood-ashes, and a suitable artificial fertiliser. Do not allow the roots to become dry, but examine them twice daily in this respect, and well water any that need moisture. Occasional doses of diluted liquid manure, made from deer manure, or from the droppings in cow-sheds will prove of great benefit, especially in the case of heavily-cropped trees. Syringe the trees with soft water daily, and ventilate the structure liberally both by day and night. Promote the formation of spurs upon Plum and Pear trees by stopping the shoots; also remove superfluous growths upon Peach and Nectarine trees, especially those that were overlooked when the trees were disbudded.

Fig trees in pots.—Large specimens that were forced early should, as soon as they have matured their second crop of fruit, be thoroughly cleansed of scale and red spider, if any be present, with a solution of soft soap made at the rate of 3 ounces to one gallon of water. In the case of red spider, the specific may be applied with a strong force from the syringe, but to eradicate scale a soft brush should be used. Remove exhausted soil from the surface of the pots, and replace it with a moderately dry compost, made firm by ramming. The plants at this stage are benefited by doses of diluted liquid manures. Young trees needing increased root room should be given a shift into larger pots, that must be provided with ample material for drainage. A compost consisting of fibrous loam, mixed with crushed mortar rubble, wood-ashes, and bone meal, or horse manure, should be used. The new soil should be in a fairly dry condition, and be made quite firm in the pots. Encourage fresh root action by placing the trees in a glass-house, where the atmospheric temperature can be maintained at 60°. Syringe the trees daily, and after a few weeks' time gradually increase the amount of ventilation until the trees are sufficiently hardened to be placed out-doors upon a firm bed of ashes.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Appointments for July.

WEDNESDAY, JULY 1—
Newcastle-upon-Tyne Flower Sh. (3 days). Ipswich and East of Eng. Hort. Soc. Sh. Hanley Park Floral Fête (2 days). Sutton (Surrey) Rose Sh.

FRIDAY, JULY 3—Nat. Rose Soc. Exh. in Regent's Park.

SATURDAY, JULY 4—
Soc. Franc d'Hort. de Londres meet. German Gard. Soc. meet.

TUESDAY, JULY 7—
Roy. Hort. Soc. Summer Exh. at Holland Park (2 days). Wolverhampton Floral Fête (3 days). Nat. Amateur Gard. Assoc. meet. Bath Rose Sh. (2 days).

WEDNESDAY, JULY 8—Croydon Flower Sh.

THURSDAY, JULY 9—Newmarket Fl. Sh.

MONDAY, JULY 13—
United Hort. Ben. and Prov. Soc. Com. meet.

WEDNESDAY, JULY 15
Hereford and W. of England Rose Sh. Women's Agric. and Hort. International Union Exh. at Regent's Park.

SATURDAY, JULY 18—German Gard. Soc. meet.

TUESDAY, JULY 21—
Roy. Hort. Soc. Coms. meet. British Gard. Assoc. Ex. Council meet. National Rose Sh. at Manchester. Highland Agric. Soc. Sh. at Aberdeen (4 days).

WEDNESDAY, JULY 22—
Nat. Carnation and Picotee Soc. Exh. at Hort. Hall, Westminster. Cardiff Fl. Sh. (2 days).

THURSDAY, JULY 23—Roehampton Fl. Sh.

FRIDAY, JULY 24—
Nat. Sweet Pea Soc. Exh. at Roy. Hort. Hall, Westminster.

WEDNESDAY, JULY 29—
Bishop's Waltham Fl. Sh. Midland Counties Sweet Pea Soc. Exh. at Wolverhampton. Chesterfield Fl. Sh.

THURSDAY, JULY 30—
Royal Lancashire Agric. Soc. Sh. at Manchester (4 days).

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich 61·6°.

ACTUAL TEMPERATURES—
LONDON.—*Wednesday, June 24* (6 P.M.) Max. 75°; Min. 55°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, June 25* (10 A.M.). Bar. 30·3; Temp. 59°; *Weather* Overcast.

PROVINCES.—*Wednesday, June 24* (6 P.M.). Max. 68° Chelmsford; Min. 54° Lancaster.

SALES FOR THE ENSUING WEEK.

FRIDAY NEXT—
Importation of Cattleya Trianæ, also choice imported and established Orchids, Orchids in flower and bud, at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

The Index Kewensis.

Botanists, especially those engaged in the systematic study of plants, as well as serious students of horticulture will welcome a new Supplement to the *Index Kewensis**. This Supplement includes the names of species of flowering plants published during the years 1901-1905; and the thanks of all interested are due to the Director of the Royal Gardens, Lt.-Col. Prain, and the herbarium Staff for this useful compilation. Only those who were working before the publication of the *Index*, less than 20 years ago, can fully appreciate its value, and that of the supplements. It is so simple a matter to turn up the name in the *Index*, that those who have not been obliged to work without it can hardly realise the amount of research which was often required to get at the earliest publication of a name, or to collect the names of the various species of a genus. That the *Index* has been used in ways in which it should not have been used, for instance, as authoritative for generic or specific reductions, does not detract from its value as an index indicating the place of publication of genera and species. While it may be helpful to know that genus or species A has been referred to genus or species B, it is the duty of the worker to satisfy himself as to the botanical validity of such reference. An illegitimate use of the *Index* by careless or thoughtless workers has been the source of no little trouble, and added not a few names to synonymy.

A list of new species or new names which have appeared during a period of five years is of interest as giving some idea of the work done during that period, and the fact that the present Supplement includes 194 pages, each with three closely-printed columns, indicates that systematists have not been idle. A glance through the pages gives an insight into the character of the work done. The eight columns of new names under Crataegus, credited to three American botanists, shows that this genus is becoming as troublesome for workers in America as is Rubus in Europe; the latter, however, keeps up the running with eight columns also. It is an instance of the difficulty experienced in dealing with genera containing highly variable species, a difficulty which makes their critical study impossible except for the extreme specialist. The Hawkweeds (Hieracium) are disposed of in a column, but, in addition, a useful list is given of the literature dealing critically with European forms. A column and a half under Impatiens, the great majority credited to *Hook. f.*, is a gratifying record of another important contribution to Indian botany, and of the remarkable energy of the veteran botanist. Progress in important floristic works such as the *Flora Capensis* and the *Flora of Tropical Africa* accounts for a preponderance of new names in the genera of certain families, such as a column and a half of new Heaths from South Africa; and similar evidence is found of advance in the great series of monographs—*Die Pflanzenreich*—edited by Dr. Engler of Berlin. The fact that very much more remains to be done in careful botanical exploration, especially of the tropics, is shown by the large number of novelties which any good collector brings home. For instance, under Calceolaria 29 new species are recorded from the work of three collectors in Central and South America.

New or resuscitated views as to limitations of genera are responsible for many of the new names. Thus, the American botanist, Prof. E. L. Greene, is of opinion that the groups Bistorta, Persicaria, and Bilderdykia, which Linnæus put together under Polygonum, should be regarded as genera, hence we find under each of these three names a long list of new combinations due to Greene. This, by the way, affords an instance of a kind of botanical selection exercised by the compilers of the *Index*; Bistorta and Bilderdykia are printed in the roman type used for synonyms, whereas Persicaria is given the honour of clarendon type, and thus its claim to generic rank is allowed. Similarly with two genera of Ochnaceæ established by Van Tieghem, due not to a new discovery, but the result of a critical investigation of the order, one, Polyochnella, is allowed, the other, Campylospermum, is tabooed. These are instances of that kind of information which, though often extremely useful, we have no right to expect from an index, and with regard to which each worker must satisfy himself.

We cannot, however, refrain from regretting the omission of the date from the great majority of the citations; its inclusion would have been a useful addition, and would not have materially increased the labour of compilation.

* *Index Kewensis* Plantarum Phanerogamarum, Supplementum III. (1901-1905); Roy. pp. iv. 194. Clarendon Press, Oxford, 1908. Price 28s. net.

NATIONAL ROSE SOCIETY.—The summer exhibition, which is to be held on Friday, July 3, in the gardens of the Royal Botanic Society, Regent's Park, promises to be one of the finest the National Rose Society has held for many years. The weather generally has been favourable for Roses, and this year there has been an absence of late spring frosts, while during June the cold periods have never lasted more than a day or two, so that the growth of the plants has at no time received any serious check. Among interesting new features of this year's exhibition will be competitive groups of the varieties which obtained the first, second, and third places in the recent ballot for the best dwarf and climbing Roses for ordinary garden cultivation. The hon. secretary is Mr. EDWARD MAWLEY, Rosebank, Berkhamsted, Herts.

NATIONAL CHRYSANTHEMUM SOCIETY.—We are informed by the secretary that the annual Outing will, this year, take place on Monday, July 27, when, by special permission, a visit will be paid to the Royal Gardens at Frogmore. The party will travel to Windsor Station, and immediately proceed to the gardens. Lunch will be served at Layton's Restaurant at 1.30 p.m. After lunch there will be time for a short visit to St. George's Chapel, and at 3.30 p.m. the party will embark at Windsor Bridge on the steam launch "La Marguerite" for a trip up the river. A halt will be made at Maidenhead for tea at the Dumb Bell Restaurant (about 5.30), and after tea the party will return so as to reach Windsor in time to catch the 8.28 p.m. train to Paddington. The price of tickets, inclusive of the railway fare to and from Windsor, launch to Maidenhead and return, lunch and tea, will be ten shillings and sixpence.

YORKSHIRE GALA.—Notwithstanding the adverse weather conditions of the opening day, this show proved a success, the attendance of the public on the second and third days being very large. The deputation of the Royal Horticultural Society, including the President, Sir TREVOR LAWRENCE, Bart., were entertained to a banquet on the evening of Wednesday, 17th inst., by the LORD MAYOR of York. Four Gold Medals were offered for the best exhibits of Orchids, stove plants, trees and cut flowers respectively. The winners of these medals were announced in our report, but after this was dispatched the Committee granted four additional Gold Medals, the recipients being Messrs. KER & SONS, Liverpool; SUTTON & SONS, Reading; WEBB & SONS, Wordsley; and JOHN PEED & SON, West Norwood. In addition to having the Gold Medals of the Yorkshire Society and the Veitch Memorial Trustees, Lieut.-Col. HOLFORD (gr. Mr. Alexander) was awarded the Gold Medal of the Royal Horticultural Society.

FLOWERS IN SEASON.—From Messrs. KELWAY & SONS, Langport, Somersetshire, we have received a beautiful bouquet of Pyrethrum roseum. There are single and double varieties, and the colours are variable and attractive. Double Pyrethrums are as ornamental for the flower border as they are for use in a cut state, and in this latter condition they will last effective for a considerable period. Some magnificent Pæonies have also been sent us by Messrs. KELWAY.

———Messrs. W. BULL & SONS have sent us unusually well-flowered sprays of Bougainvillea "Maude Chettleburgh." This variety formed the Supplementary Illustration to the *Gardeners' Chronicle*, November 12, 1904, and it is remarkable for the intense colour of the ornamental bracts.

———Some specimens of varieties of Cytisus scoparius Andreanus, sent us by Mr. T. SMITH, Newry Nurseries, Ireland, show what diversity there is now to be seen in this form of the common Broom. The varieties include The Ghost, with pale-coloured flowers, in which the crimson colouring is almost absent; Newry Seedling, in which the crimson markings are rather more pronounced; May Fly, a very handsome variety, with large flowers in which the rich orange and crimson shades are very conspicuous; Fire Fly, Daisy Hill, Butterfly, Moonlight (a very distinct variety, almost one shade of yellow), Sulphureus, Fulgens, and other attractive varieties that are at present unnamed.

———A consignment of specimens from the Coombe Wood Nurseries of Messrs. JAMES VEITCH & SONS, LTD., illustrate some of the choicer trees and shrubs in flower at the moment, some of which, although familiar at the exhibitions, are not planted nearly so commonly as they should be. Styrax japonicum (fig. 166 in *Gardeners' Chronicle*, December 12, 1885, p. 745), with its pure white, single flowers, is a handsome shrub, and the sprays, if cut and arranged in vases, are exceptionally pleasing. Rodgersia pinnata (fig. 44 in *Gardeners' Chronicle*, August 23, 1902, p. 131) is one of the boldest flowering plants suitable for planting near water or in the damper portions of a rockery, and has pinkish panicles of flower. The variety alba now received has white flowers and may also be used in a cut state in a bold scheme of decoration. Ozothamnus rosmarinifolius is a shrub with small white flowers that we have frequently described in these columns. Magnolia parviflora is one of the most striking species of this handsome flowering genus. Robinia Neo-mexicana, a species from the Rocky Mountains, and R. Decaisneana, a fragrant variety of the false Acacia. Lonicera etrusca superba is a very fine variety of this brightly-coloured species, and the other specimens include Euonymus fimbriatus and Berberis vulgaris integerrima.

———A strain of Streptocarpus sent us by Messrs. STORRIE & STORRIE, Glencarse Nurseries, Perth Line, are commendable for their large flowers and brilliant and varied colours. The individual spikes are very strong, usually reaching a height of about 12 inches, but occasionally as much as 20 inches. The colours range from white to crimson and violet.

———Messrs. HUGH LOW & CO., Bush Hill Park Nursery, have sent us a flower of a variety of Souvenir de la Malmaison Carnation. In appearance it is like an improved form of the pink-flowered type. Messrs. Low state that this variety is raised from Lady Grimston crossed with Princess of Wales. The outer petals are very much better in form than those of the original type, and the colour of the whole flower is of a softer yet richer tone of pink. It bears the name of "The Gala," and we are informed that the variety will be exhibited at the Holland Park Show.

MR. ATLEE BURPEE ON THE PARIS SPRING SHOW.—Writing in the *American Florist* of June 13, Mr. ATLEE BURPEE, now on a visit to Europe, says: "I was fortunate in spending May 23 in Paris and vicinity. I then had an unexpected treat in viewing the Cours la Reine exposition of the Societe Nationale d'Horticulture de France. By far the largest of the many fine exhibits and most notable was that of Messrs. VILMORIN, ANDRIEUX & CO. I could not have believed it possible that any firm would go to so much trouble and expense for an exhibition of one week; in fact, never have I seen at one time and in any one group such a variety and grand display made by any firm, even at the World's Fair." Mr. BURPEE then expresses the hope that such a display could be made in America and gives full details of the exhibit by Messrs. VILMORIN & CO., to which we also alluded briefly in our report of the Paris Spring Show, published in the issue for June 6, p. 374.

FIG. 187.—HELIANTHEMUM ROSEUM IN FLOWER. (See text p. 420.)

LAWES AGRICULTURAL TRUST.—The Committee of the Lawes Agricultural Trust held their annual meeting for the inspection of the Rothamsted Experimental Station on June 19. A vote of condolence was addressed to Lady EVANS, expressing the sympathy of the committee in the loss she had sustained through the death of Sir JOHN EVANS, who had been Chairman of the committee since the foundation of the Trust, and to whose endeavours the organisation and extension of its work had been largely due. In the afternoon the laboratory and field experiments were inspected by a small party, which included the Duke of DEVONSHIRE, Sir J. T. BRUNNER, M.P., Sir HUGH SHAW STEWART, Sir A. K. ROLLIT, Col. E. H. CARLILE, M.P., Mr. J. F. MASON, M.P., Mr. B. MUNRO FERGUSON, M.P., Mr. F. G. OGILVIE, Professor W. A. TILDEN, and Dr. B. DYER.

ROYAL SOCIETY OF ARTS.—The annual conversazione will take place at the Natural History Museum, Cromwell Road, London, S.W., on Thursday next, July 2. The reception, by Sir STEUART COLVIN BAYLEY, K.C.S.I., C.I.E., Chairman, and other members of the Council, will be held in the Central Hall from 9 to 10 p.m.

*** LONDON SOCIETY OF FRENCH GARDENERS.**—We have received for the nineteenth year in succession the annual *Bulletin* of this very flourishing and useful Society, which now occupies a prominent position among the leading European horticultural societies, for it is supported by most of the leading English, Belgian, and French nurserymen, besides others holding responsible positions as gardeners and curators of public gardens at home and abroad. The *Bulletin* for 1908 contains a record of the work during the past year, and is described by our contemporary, *La Tribune Horticole*, of Brussels, whose editor, M. LOUIS GENTIL, was once the secretary of the Society, as being decidedly the finest that has ever yet been issued. There are several excellent illustrations, Mr. THOMAS BEVAN, an old friend of the Society, being honoured by having his portrait as the frontispiece, accompanied by a biographical notice. The annual report, rules, list of officers, and the ever-increasing lists of members are also given, together with the Library Catalogue and reports of the monthly meetings. In the literary part of the *Bulletin*, we note with pleasure the heading "La Fête Schneider," which contains an account of the several meetings in England and in France at which Mr. GEO. SCHNEIDER was entertained to celebrate his well-deserved promotion to the rank of Officier du Merite Agricole. We also draw our readers' special attention to the lengthy and interesting article by M. P. AQUATIAS, entitled "Intensive Culture of Vegetables—French System," a subject that is now attracting much attention on the part of English growers. The article is written in English, an innovation for the benefit of English members of the Society. The subjects dealt with include choice of the ground, materials, lights, shed, disposal of the grounds, horse-dung, hot-beds, culture, winter crops, Spinach, Lamb's Lettuce or corn salad, Passion Lettuce, Sorrel, Chervil, Strawberries, a calendar of work for the various months, choice of seeds, diseases and insects, and an explanatory plan of a French garden, double-paged, is given for an area of 2 acres. Other literary matter includes papers in French on such subjects as Carnations in England, the Temple Show, Roses, enemies of horticulture, horticulture in Egypt, the Crystal Palace Chrysanthemum Show, report of a visit to Messrs. CUTBUSH & SON'S nursery, and notices of new books. These articles are written mostly by the young members of the Society who are resident in England, and are read at the monthly meetings of the Society. The meetings take place in the evening of the first Saturday in the month at the Society's meeting place. The French Horticultural Society is practically a mutual improvement society, and has no shows to help to increase its funds. Notwithstanding this fact, it has a balance in round figures of £232, besides a sum in the hands of the Paris Committee of the Society. The annual dinner is held in January, and this *Bulletin* contains a full report of the last one, at which Mr. H. J. VEITCH, of Chelsea, presided.

* *Bulletin de la Société Française d'Horticulture de Londres.* (Office of the Society, 66, Long Acre, London, W.C.)

FRENCH HORTICULTURISTS IN LONDON.—At the meeting of the Royal Horticultural Society on Tuesday last, the President and Council received a deputation of about 100 members of the Société Nationale d'Horticulture de Française, entertaining them to a light luncheon. The visitors included the President, Mons. VIGER, and MM. LEBOUF (treasurer), ABEL CHATENAY (secretary), and MAURICE DE VILMORIN.

HELIANTHEMUM ROSEUM.

THIS member of the "Sun Rose" family is now regarded as a variety of H. polifolium, a species coming very near the more woolly-leaved forms of H. vulgare. The variety is a most attractive one from the garden point of view, and the illustration at fig. 187 will serve to show how decorative the Helianthemums are when seen in a goodly mass. Like all the sub-shrubby species and their varieties, H. roseum is especially suited for sunny ledges of rockwork or sloping rocky ground, and in these positions the plants will thrive for a number of years with but little attention. Some of the species of Helianthemum are apt to become straggling in growth in certain localities, and where this is seen the garden shears should be used without hesitation, in order to induce a branching habit and increased vigour. H. roseum has blossoms of a rosy red hue, which are very showy when seen in the sunlight. *E. J.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

THE PRINCIPLES OF MANURING.—The leading article on p. 384 places before its readers a subject of much interest to gardeners and agriculturists, but its use to the gardener is what concerns us most. The composition of the ash of plants and trees, as shown by analysis, is sometimes given as an indicator of what a plant may require, and it has been recommended in many works on this subject that all the cultivator has to do is to supply the particular ingredients set forth in the analysis to grow the plants and fruits to perfection. Now it appears to me that these scientific teachers and blenders of manures have started at the wrong end, for they seem to treat all soils the same. If when stating the results of their experiments they also gave the composition of the soil in which the subjects grew, we then might be on the right road to success. Take, for instance, Potato manures. There are several on the market, all recommended as being the one thing needful to ensure a good crop, either for table use or exhibition. They may produce some tubers for the latter purpose, but for consumption the crop may be worthless. I have tried many of these manures, and the results said to have been obtained by their use may be quite true in some soils, but that does not prove that they will be equally valuable in others. The same thing applies to other subjects grown. We want an analysis of the soil with which we have to deal obtainable at a moderate price. We then should be better able to supply any deficiencies which such analysis showed, or abstain from putting into the soil what was not required. The presence of iron in the soil has, as you say, long been recognised as being productive of high colour. This is most noticeable in the Hereford district, and in soils of Devon and Somerset. If it is not iron, what is the cause of this high colour which these red soils produce? Dr. Griffiths is evidently a great believer in the use of iron, for in his work on *Special Manures for Garden Crops* he frequently recommends it, and says "It is a direct and an indirect plant food." But if Dr. Griffiths had stated in what kind of soil he carried out his experiments, the value of his observations would have been greatly enhanced. I have used his recipes for many things, but in our soil they have been useless. For Palms he recommends with other ingredients iron sulphate, and also in addition a few crystals of iron sulphate being placed on the surface of the soil. With our soil the best colouring agent and fertiliser I have found for Palms is nitrogen. I think we have too much iron in our soil already, or some other similar substance. We certainly have something in it that Muscat vines cannot assimilate; this type of vine merely exists. Now the soil used for these vines is the top 2 inches of turf from the Deer Park, a soil that generally suits all else which we grow. Why should it not suit Muscats? *T. H. Slade, Poltimore Gardens, Devonshire.*

A NEW IVY.—In your issue of June 13, p. 389, we notice you report the new variegated Ivy exhibited by Mr. Russell as having been raised by him. We would point out that this variety (Hedera Helix dentata variegata) was raised by us in our own nurseries and was supplied to Mr. Russell by us. *Pennell & Sons, Lincoln.*

VAPORITE FOR WIREWORM.—Vaporite is often recommended for the destruction of wireworms, but it is absolutely useless on our gravelly land, even at double the strength recommended. It is better to apply sulphate of ammonia and superphosphate, as it stimulates growth, and thus assists the plants to resist an attack. *G. H. H. Wassell, Heath End House, Baughurst, Basingstoke.*

SOCIETIES.

ROYAL HORTICULTURAL.

JUNE 23.—There was a good display of flowers, fruits, and a few vegetables at the meeting on Tuesday last. Garden flowers formed the major portion of the exhibition, but there were also displays of Orchids, Crotons, Carnations, Roses, Gloxinias, Caladiums, &c.

The meeting was visited by a party of French horticulturists, who were entertained by the Council to luncheon. The Orchid Committee granted no fewer than five Botanical Certificates besides other awards; the Floral Committee conferred Awards of Merit upon thirteen novelties. At the afternoon meeting of the Fellows a lecture was given by the Rev. Prof. Geo. Henslow on the "Absorption of Rain and Dew by the Green Parts of Plants."

Floral Committee.

Present: H. B. May, Esq. (in the Chair), and Messrs. Chas. T. Druery, W. A. Bilney, Jas. Hudson, Jno. Green, G. Reuthe, C. Blick, R. W. Wallace, Jno. Jennings, Chas. Dixon, Jas. Dixon, Jas. Douglas, Chas. E. Pearson, J. H. Barr, W. Cuthbertson, H. J. Cutbush, E. H. Jenkins, R. C. Notcutt, E. A. Bowles, Walter T. Ware, R. Hooper Pearson, and R. C. Reynolds Nevill.

Messrs. JAMES VEITCH & SONS, LTD., King's Road, Chelsea, contributed several pleasing displays. On the table they usually furnish with indoor plants, they displayed Gloxinias, Kalanchoe flammea, K. kewensis, Swainsonia galegifolia and Lobelia tenuior. The Gloxinias were noteworthy for their general excellence, both in regard to their culture and their wide range of colours. Opposite this exhibit was another of hardy annuals, and a selection of Spanish Irises. Under the wall opposite the entrance the same firm showed Pæonies in great variety, Campanula media, a batch of Eremurus Warei, Rodgersia pinnata, and other subjects. (Silver-Gilt Flora Medal.)

Messrs. H. B. MAY & SONS, The Nurseries, Edmonton, showed a representative collection

of Codiæums (Crotons)). Most of the old favourite varieties were included, and all gave evidence of skilful culture. A selection of the best kinds displayed includes Reidii, with broad, handsome foliage; Mooreanum, having handsome green and yellow leaves that recurve at their apices; Duke of Buccleuch, the young foliage being bright yellow; Edmontoniense, richly coloured with red and gold; Invicta, Imitabile, &c. (Silver-Gilt Flora Medal.)

Messrs. WM. CUTBUSH & SON, Highgate, London, N., showed Carnations of fine quality, Metrosideros floribunda, Calceolaria "Decorator," Roses, the bronzy-red-leaved Coleus Cordelia, Astilbes (Spiræas), &c. (Silver-Gilt Banksian Medal.)

Messrs. JOHN LAING & SONS, Forest Hill, London, put up a semi-circular group of handsome Caladiums, with Selaginellas, Dracænas, Ficus elastica, Nertera depressa, &c., interspersed. (Silver Banksian Medal.)

Anthuriums of the Andreanum section were shown by Mr. A. TRUFFAUT, 40, Rue des Chantiers, Versailles. There were several varieties, all differing in the degree of colouring in the spathes. The largest inflorescence was labelled awarded a Silver Flora Medal. Other exhibitors of Roses were Messrs. W. & J. BROWN, Peterborough (Silver Banksian Medal); Messrs. BEN CANT & CO., Colchester (Silver Banksian Medal); Messrs. PAUL & SON, Cheshunt, who also displayed Pæonies and other hardy flowers (Silver Flora Medal); Messrs. W. PAUL & SON, Waltham Cross, Herts.; and Messrs. W. SPOONER & SON, Arthurs Bridge Nursery, Woking (Bronze Banksian Medal).

Mr. JAMES DOUGLAS, Edenside, Great Bookham, showed a large number of Pinks, in all 150 plants, embracing about 30 varieties. If we were to select one variety only, our choice would be the beautiful Snowflake, white, as its name implies, but with a suspicion of rose colour in the bases of the petals.

Mr. W. J. GODFREY, Exmouth, Devon, displayed a number of show Pelargoniums and a batch of small plants of Solanum Wendlandii, all well-flowered. (Silver Banksian Medal.)

Messrs. WM. BULL & SONS, King's Road, Chelsea, showed Spanish Irises in variety, and another exhibitor of these seasonable flowers was M. U. HOMAN, Holland. (Silver Banksian Medal.)

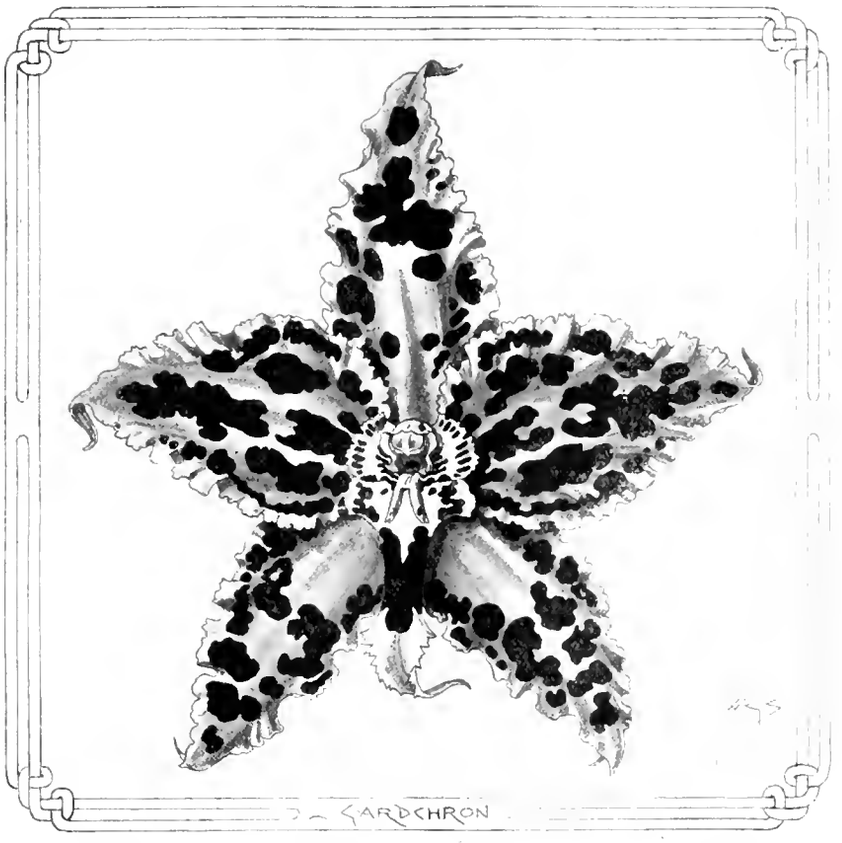

FIG. 188.—ODONTOGLOSSUM × PHŒBE: FLOWER WHITE WITH REDDISH-PURPLE MARKINGS.

(First-Class Certificate at R.H.S. meeting on June 9. See description on ante p. 390.)

Queen Alexandra, but the big bract was only partially coloured red, the remaining portion being leaf-like.

Messrs. HUGH LOW & Co., Bush Hill Park, Enfield, exhibited pot plants of Souvenir de la Malmaison Carnations. The plants were examples of good culture, the blooms being very fine in quality. (Silver Banksian Medal.)

Mr. ROBERT NEAL, Trinity Road, Wandsworth, displayed vases of Sweet Peas.

Messrs. H. CANNELL & SONS, Swanley, Kent, showed a large batch of Gloxinias and boxes of Roses. The Gloxinias included such fine varieties as Lady Dyke, Miss Matthews, Purple Queen, Prince of Wales, &c. (Silver Banksian Medal.)

Mr. WM. PROFITSLICH, Twickenham, exhibited on behalf of Messrs. Waverin and Kruijff pink-flowered Astilbes (Spiræas), the variety Queen Alexandra being especially fine.

Several displays of Roses were seen. Mr. GEO. MOUNT, Canterbury, showed a group in his inimitable style, and for which he was awarded a Silver Flora Medal. Other exhibitors of Roses were Messrs. W. & J. BROWN, Peterborough (Silver Banksian Medal); Messrs. BEN CANT & CO., Colchester (Silver Banksian Medal); Messrs. PAUL & SON, Cheshunt, who also displayed Pæonies and other hardy flowers (Silver Flora Medal); Messrs. W. PAUL & SON, Waltham Cross, Herts.; and Messrs. W. SPOONER & SON, Arthurs Bridge Nursery, Woking (Bronze Banksian Medal).

Mr. AMOS PERRY, Enfield, Middlesex, staged a beautiful group of hardy flowers, amongst which spikes of Delphinium were a feature. The exhibit was well arranged, the foreground having a tank with Nymphæas and other water-loving plants. In the centre and at the back of the water-garden was a batch of tall Eremurus and Liliums in many varieties. The front was of stonework, among which were introduced Ferns, Funkias, Calla Rehmannii, Epimediums, &c. A selection of seasonable garden flowers was also included in the group. (Silver-Gilt Flora Medal.)

Messrs. DOBBIE & Co., Rothesay and Mark's Tey, showed vases of Spanish Irises in great variety and all of fine quality. Notable varieties were Soleil d'Or; Pearson, heliotrope and violet colourings, with yellow on the falls; Thunderbolt, having brown and yellow falls which are extremely pretty; L. Unique, white falls with blue in the other segments; L'Innocence, white with yellow marking; La Nuit, King of the Blues, &c. (Silver Banksian Medal.)

Messrs. BAKER'S, Wolverhampton, showed an assortment of choice garden flowers and some Alpine plants, disposed in a setting of Virgin cork. A large, deep-yellow-coloured Gaillardia was shown under the name of Lady Rolleston. (Silver Banksian Medal.)

Messrs. WALLACE & Co., Kilnfield Nurseries, Colchester, staged many select garden flowers, including several hybrid Heucheras, Pentstemon pygmæus, some splendid spikes of Lilium monadelphum Szovitzianum, L. Hansonii, Gladiolus Ne Plus Ultra, Allium albopilosum, &c. (Silver-Gilt Banksian Medal.)

Messrs. BARR & SONS, King Street, Covent Garden, London, exhibited an assortment of hardy flowers, amongst which were varieties of Gladioli, Irises, Campanulas, hardy Nymphæas, Delphiniums, Geum, Pæonies, and other showy subjects. (Silver Banksian Medal.)

The GUILDFORD HARDY PLANT NURSERY, showed hardy succulent plants, principally Sedums and Sempervivums.

Messrs. JAS. KELWAY & SON, Langport, Somerset, showed Pæonies, Delphiniums, and Pyrethrums. Amongst the Delphiniums was a new variety with deep cobalt blue flowers, labelled King Edward VII. (Silver Banksian Medal.)

A batch of hybrid Delphiniums was shown by C. FERGUSON, Esq., Weybridge (gr. Mr. F. W. Smith). The best were labelled Samara (fine deep blue colour), Kandaules (magenta), Idaia (Cambridge blue), Polykrates, and Hammurabi

Other exhibitors of garden flowers were Messrs. JOHN PEED & SON, West Norwood, London; Mr. GEO. REUTHE, Keston, Kent (Silver Flora Medal); T. S. WARE, LTD., Feltham, Middlesex; Mr. J. R. BOX, West Wickham; the Misses HOPKINS, Shepperton-on-Thames; and the COTTAGERS' SOCIETY, Letchworth.

Flowering shoots of Schizophragma hydrangeoides were shown by Mrs. HOLDEN, Nuttall Temple, Notts.

A batch of small plants of Erica cinerea coccinea was exhibited by H. WHITE, Esq.

AWARDS.

AWARDS OF MERIT.

Anthurium "President Viger."—A very bold Anthurium with large, deep red-coloured spathe, similar to A. Andreanum. This was exhibited by Mons. A. TRUFFAUT, Versailles, who contributed several other additional varieties.

Begonia Col. Lausedat.—A neat-habited, tuberous-rooted variety, with double flowers of bright, rich yellow. It will be valuable for cultivation as a pot plant, and for bedding out in summer-time. Shown by Messrs. JAS. VEITCH & SONS, LTD.

Campanula Raddeana.—This is a new hardy species raised from seeds obtained from the Ural Mountains. The plant and flowers as shown were 9 or 10 inches high, and the growth very slender. The leaves are scarcely ½-inch in diameter, ovate, and much crenated. The corolla is 1 inch across, perfectly bell-shaped, deep violet-purple in colour, and having the yellow pistil obtruding ½ inch. The divisions of the calyx have very hairy margins. Shown by Mr. G. REUTHE.

Delphinium Cambyses.—This very fine variety, with large double flowers, coloured pale blue with white centre, was exhibited by C. FERGUSON, Esq.

Eremurus Bungei magnifica.—This is a very robust form of the yellow-flowered species E. Bungei, with much-enlarged inflorescence. Shown by Messrs. J. VEITCH & SONS, LTD.

Erica cinerea pygmea.—A dwarf form of this ornamental Heath, and the plants shown were not more than 4 inches high. With its brilliantly-coloured flowers this plant will be valued for the rockery. Shown by Mr. G. REUTHE.

Eccremocarpus Mikado.—A brilliantly-coloured orange-scarlet variety, with a suspicion of copper shade. Shown by Mr. W. H. GARDINER, Mill Street, St. Osyth.

Hybrid Sweet Briar Refulgens.—This variety, exhibited by Messrs. W. PAUL & SON, is probably the result of a cross between a hybrid Briar back again upon a Rose, as the fragrant foliage partakes much more after the Rose than the Briar. The semi-double flowers are 3 inches or more in diameter, and are produced in

moderate clusters The colour is purplish-crimson with a white centre.

Knipofia Goldelse.—A very slender-growing yellow variety of only moderate height (see illustration in *Gardeners' Chronicle*, July 21, 1906). Shown by Messrs. WALLACE & Co.

Pelargonium Fred. T. Hamilton.—This is evidently a cross between a zonal-leaved and an ivy-leaved variety. The green leaves are of sufficient thickness to cause them to break when doubled. The flowers are borne on spikes 1 foot in length, in excellent trusses, and each bloom is semi-double and of good form. The colour is a vivid shade of carmine-scarlet, with very slight violet markings on the upper petal. Shown by Messrs. W. H. ROGERS & SONS, LTD., Basset, Southampton, who submitted it as a "zonal" variety.

Stokesia cyanea alba.—This white variety of a well-known hardy plant was exhibited by Mr. AMOS PERRY.

Sweet Pea Dobbie's Mid-Blue.—A flower of moderate size with erect standard, the award being given for its degree of blue colouring.

Sweet Pea The King.—A variety having reddish-coloured flowers shaded with orange. Shown by Messrs. DOBBIE & Co.

Orchid Committee.

Present: J. Gurney Fowler, Esq. (in the Chair), and Messrs. Jas. O'Brien (hon. sec.), Harry J. Veitch, de B. Crawshay, H. Little, W. Boxall, J. Forster Alcock, Stuart Low, F. Sander, R. G. Thwaites, F. J. Hanbury, A. A. McBean, W. Cobb, J. Charlesworth, A. Dye, W. H. White, H. A. Tracy, H. Ballantine, Gurney Wilson, R. Brooman-White, N. C. Cookson, and C. H. Curtis.

Messrs. CHARLESWORTH & Co., Heaton, Bradford, were awarded a Silver Flora Medal for a select group, containing choice plants throughout. At the back of the group were some splendid varieties of Lælio-Cattleya Canhamiana. Amongst other plants of special note were a home-raised Cattleya Mossiæ Wageneri, with four pure white flowers; C. Mossiæ Mrs. A. Goodson, the beautiful flower being coloured rose-purple, and handsomely flaked with white; and C. Mendelii alba, a finely-shaped, white variety, with a slight pink tinge on the front of the lip. Other plants included Odontoglossums, Miltonias, Phalænopsis, and Ornithocephalus grandiflorus.

DE B. CRAWSHAY, Esq., Rosefield, Sevenoaks (gr. Mr. Stables), was voted a Silver Flora Medal for a very interesting group of hybrid Odontoglossums, all raised at Rosefield The plants were magnificently grown and finely flowered. Among them were several good forms from the same batch which gave the handsome Odontoglossum "Queen Alexandra" Crawshayanum. The selection of about 30 plants contained the new hybrid between O. Hallio-crispum and O. triumphans, a pleasing yellow flower heavily blotched, and nearest in appearance to O. Leo (Hallii × triumphans), which was also shown One of the largest and best was O. Crawshaynum (Harryanum × Hallii), which had a very large labellum; O. Amneris, O. Urania, O. Nemesis, and O. Astarte were also well shown, together with a very deep blood-red variety of Renanthera Imschootiana

Messrs. STANLEY & Co., Southgate, secured a Silver Banksian Medal for an effective group of varieties of Cattleya Mossiæ, C. Mendelii, C. Warneri, and C. Adaudiæ Among the examples of C. Mossiæ were many white forms, including C. M. Heather Bell, pearly-white, with a lavender-blue tint on the lip; C. M. Blue Bell, white, with a pale-pink tinge on the front of the lip; C. M. Trodiæ, clear white, with chrome-yellow tint in the centre of the lip, &c.

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr. Mr. Hopkins), sent Cattleya Mendelii Majestica, a very large flower, white, with a slight lavender tint on the petals, the tube of the lip being pure white, the broad front rosy-mauve; and C. Mendelii Venus, a broad-petalled, clear-white flower, the central area of the lip being yellow, a few purple lines extending from the base to the front, which is rose-purple veined with white

HENRY LITTLE, Esq., Baronshalt, Twickenham (gr. Mr. Howard), showed Lælio-Cattleya Iris-alba, Little's variety, a large, light-rose coloured flower, with claret-purple front to the lip

G. HAMILTON SMITH, Esq., Killoran, Finchley (gr. Mr. Coningsby), sent Lælio Pacavia Mrs. G. Hamilton Smith, a showy, rosy-lilac flower, with claret veining on the lip.

H. S. GOODSON, Esq., Fairlawn, Putney (gr. Mr. G. E. Day), showed Odontoglossum crispum Mrs. Humphrey, a good white flower with clusters of light-brown spots on the inner parts of the segments

J. FORSTER ALCOCK, Esq., Exhims, Northchurch, showed a seedling Sobralia, with flowers of medium size tinged with claret colour.

H. J. ELWES, Esq., Colesborne, staged a small group of well-grown Thunias.

Monsieur MERTENS, Ghent, showed six hybrid Odontoglossums.

Lt.-Col. G. L. HOLFORD, C.I.E., C.V.O., Westonbirt (gr. Mr. H. G. Alexander), showed a very fine plant of Dendrobium Dalhou-nobile, with flowers as large as those of D. Dalhousianum, but produced along the pseudo-bulbs, and coloured as in D. nobile.

SIR TREVOR LAWRENCE, Bart., K.C.V.O., Burford (gr. Mr. W. H. White), showed the singular pale-green Catasetum planiceps; Epidendrum aromaticum, and others which will be found under Awards.

AWARDS.

FIRST-CLASS CERTIFICATE.

Odontoglossum crispum Princess of Wales, from Baron Sir H. SCHRÖDER, The Dell, Egham (gr. Mr. H. Ballantine). One of the largest and best of the typical forms of O. crispum yet shown. The large, broad-petalled flowers are white, the sepals slightly tinged with rose, the labellum having a brown blotch in front of the yellow crest.

AWARDS OF MERIT.

Odontioda Wickhamensis (O. crispum × Cochlioda sanguinea), from G. W. BIRD, Esq., Manor House, West Wickham (gr. Mr. Redden). An elegant little hybrid, with flowers comparable with O. heatonensis (O. cirrhosum × C. sanguinea), but with segments rather broader and less acute than in that species. The flowers are tinted with rose-pink, and spotted with reddish rose.

Epidendrum varicosum, from SIR TREVOR LAWRENCE, Bart., K.C.V.O. (gr. Mr. W. H. White). A pretty and fragrant Guatemalan species, with erect, branched spikes of flowers. Sepals and petals pale green; lip white, with some purple lines at the base.

Dendrobium Jodomianum, from Sir TREVOR LAWRENCE, Bart. A very rare and pretty species received by SIR TREVOR LAWRENCE from Coorg, in the Western Ghats, India, and shown by him on February 29, 1900, when a Botanical Certificate was given. The plant is nigro-hirsute, dwarf, compact, and bears a profusion of orange-coloured flowers.

BOTANICAL CERTIFICATES.

Bulbophyllum fusco-purpureum, from SIR TREVOR LAWRENCE, Bart. A remarkable species from the Nilgiri Hills The flowers are produced in a terminal raceme, each on a long pedicel, and about an inch in length; deep brownish-purple in colour, the labellum darker The long filaments at the tips of the petals form a curious feature

Eulophia nuda, from SIR TREVOR LAWRENCE, Bart. An Indian species with stout spikes of pale-green flowers with white labellums.

Phalænopsis Imdoni, from Messrs. CHARLESWORTH & Co. The foliage is similar to that of P. Schilleriana; the flowers resemble those of P. rosea, but they are larger and with a broader and differently-shaped lip. Flowers white, tinged with rose colour. The species is a native of the Philippine Isles

Bifrenaria tetragona, from Messrs. CHARLESWORTH & Co. Flowers closely arranged around the pseudo-bulbs, wax-like, greenish, with a fleshy labellum that is white on the outside and dark purple within.

Vanda pumila, from Messrs. MOORE, LTD., Rawdon, Leeds. An extremely rare species from the Sikkim Hills, where it was found at an altitude of about 2,000 feet. It is dwarf in habit, and in general appearance resembles V. alpina and V. cristata. The flowers are borne in pairs, cream-white, with purple lines on the upper side of the ridged labellum, which differs from V. cristata in not having the diverging horns at the apex

Fruit and Vegetable Committee.

Messrs. DOBBIE & Co., Mark's Tey, Essex, showed two dozen baskets of Potatos, grown in the open in Cornwall. They were planted on February 3, and were remarkably fine samples, reminding one of best exhibition tubers. Midlothian Early, Climax, Cardinal (red), Sharpe's Victor, Beauty of Hebron, Milecross Early, and Russett Queen are some of the finer varieties shown. Adjoining the Potatos were some Radishes, both turnip-rooted and conical. White Delicacy (conical) was one of the largest kinds, and next to it was Long Ou Rave Rose a Bout Lance, the roots being as large as small Carrots. The variety labelled D'Eté Jaune d'Or Ovale was tinged with a yellowish bronze shade. White Olive Shaped, Violet Olive White Tipped, Half Long Scarlet, Long Blanc de Mai, and Woods' Early Frame appeared to be the pick of the varieties. (Silver Knightian Medal.)

The NEW SOUTH WALES GOVERNMENT exhibited a number of Apples, Seedless Oranges, and Lemons. Amongst the Apples was the handsome Rome Beauty variety, also Monroe's Favourite and Granny Smith; the latter is a large yellow-skinned variety of excellent flavour. (Silver Knightian Medal.)

An exhibit of Grapes came from the gardens of H. J. KING, Esq., Eastwell Park, Kent (gr. J. G. Weston). The varieties were Black Hamburg, Gros Maroc, Foster's Seedling, and Muscat of Alexandria. The centre bunch of three of the variety Foster's Seedling, was a fine sample; the Black Hamburgs were good bunches, and the Muscat of Alexandria, although small in berry, were well finished. (Silver Knightian Medal.)

Messrs. JAMES VEITCH & SONS, LTD., King's Road, Chelsea, exhibited vegetables grown under the "French" system of forcing. There were large Lettuces of the Green Market variety, Oxheart Cabbages, Bellot and Nantes Market Carrots, and very large Cauliflowers of the Lamblin kind.

HORTICULTURAL SHOW AT THE FRANCO-BRITISH EXHIBITION.

JUNE 24, 25, and 26.—The first of the few flower shows arranged to take place at the Franco-British Exhibition at Shepherd's Bush was opened on Wednesday last. The display was made in the Palace of Music, and the arrangement was of the stolid English type, long formal tables ranging lengthwise down the centre and sides of the hall, on which were placed the exhibits.

The one really artistic feature was seen on the Orchestra, where, on either side, Messrs. H. B. MAY & SONS, and Messrs. HILL & SONS had grouped fine collections of Ferns. But the centre, which, in the midst of such a mass of green foliage, should have been a bold bank of colour, had a low bank of hardy flowers, and some pot fruit trees. Large as the hall is, the fine arcade running all round it outside, and having one side quite open, also contained long formal banks of hardy flowers, some plants, and a considerable representation of vegetables. The most effective groups, apart from the Ferns, were of Orchids. Facing these were, on the floor, groups of ornamental foliage plants and Caladiums. On the tables behind, and throughout, were Begonias, Gloxinias, Roses, Carnations, Sweet Peas, hardy flowers; all these in very great quantities, and doubtless affording visitors much to delight them. Special features were the fine lot of fruit trees in pots from Sawbridgeworth, Cannas from Swanley, Begonias from Feltham, Sweet Peas from Mark's Tey, and the splendid vegetables from Aldenham Gardens, Reading, Wordsley, and Castle Ashby.

The primary French exhibits included a medium collection of Orchids, one of Carnations, a very large one of cut Nymphæas, set up in vases, probably 100, but not a flower open, one of gathered Strawberries, some sixty varieties, the fruits much coated with sulphur, and one of vegetables, which could not be compared favourably with the Lord ALDENHAM's collection.

The issue of a schedule of competitive classes brought very little competition, the exhibition being provided generally by means of traders' exhibits.

The awards were made by a body of jurors of both nationalities.

GARDENERS' ROYAL BENEVOLENT.

JUNE 24.—The sixty-ninth anniversary festival dinner took place on the evening of the above date at the Hotel Metropole. The Rt. Hon. the Lord Aldenham presided, and there were about one hundred and ninety subscribers and friends present.

In proposing and responding to the various toasts, speeches were made by the Chairman, and by Messrs. Harry J. Veitch (treasurer and chairman of committee), George Paul, George Munro, Mons. Viger (president of the Société Nationale d'Horticulture de Française), the Rt. Hon. Col. Mark Lockwood, M.P., and Mr. G. J. Ingram.

The secretary (Mr. G. J. Ingram) announced that the subscriptions and donations, paid and promised, amounted to upwards of £2,000.

ROYAL BOTANIC.

JUNE 17.—The summer show of the above Society was held on Wednesday in one large marquee, and though the exhibits were not very numerous, they were of considerable interest, and provided a display of varied and brilliant colours.

Messrs. PAUL & SON, Cheshunt, contributed a choice group of Pæonies, mostly double varieties, but including some excellent single varieties as well, diversified in colour and form.

Many other hardy flowers were also shown in this collection, but those which commanded most attention were the Heucheras. The same firm had a superb group of Roses in pots, and stands of cut Rose blooms representing numerous favourite old and new varieties. (Gold Medal.)

Messrs. KELWAY & SON, of Langport, Somerset, contributed an extensive and beautiful collection of Pæonies, Delphiniums, Pyrethrums and Amaryllises, for which the Royal Botanic Society's Gold Medal was awarded. The Pyrethrums included a fine double white variety named Aphrodite, a rich cream double named Alfred, and a very distinct form with primrose centre and blush outer florets.

A Silver-Gilt Medal was adjudged to Messrs. JOHN PEED & SONS, West Norwood, for a varied and interesting group of hardy herbaceous flowers, comprising large numbers of handsome Pæonies, Pyrethrums, and Irises of the leading varieties Delphiniums, Spiræas, and Heucheras were also employed with good effect.

Messrs. BARR & SONS, King Street, Covent Garden, secured a premier award, the Society's large Gold Medal, for a magnificent collection of Pæonies, Ixias, Gladiolus and Irises, with Heucheras and Campanulas. Not only were the varieties well selected and distinct, but the general arangement was also tasteful and excellent.

A Silver-Gilt Medal was awarded to Messrs. PAUL & SON, Waltham Cross, for a choice group of Roses and six boxes of the brilliant crimson hybrid Briar Rose Refulgence, a most charming addition to its class.

Messrs. T. S. WARE, LTD., Feltham, secured a Gold Medal for an excellent exhibit of single and double tuberous Begonias in fine condition. With them as a background were vases of Pæonies and Delphiniums, flanked by stands of Carnations.

Mr. S. MORTIMER, Farnham, had a charming group of Carnations, including some of the best varieties in cultivation, such as Harry Fenn (dark maroon), and Lady Bountiful (white), Victory (scarlet), Fair Maid (pale pink), and Winsor, a beautiful blush shade or delicate pink. A Gold Medal was awarded.

AWARDS.

Tea Rose Hugo Roller (PAUL & SONS).—An extremely beautiful novelty, with creamy flowers heavily margined with deep crimson, the flowers of good size and substance. (First-Class Certificate.)

Hybrid Sweet Briar Refulgence (W. PAUL & SONS).—An extremely beautiful, semi-double, fragrant Rose, deep glossy crimson, with the yellow centre stamens making a fine contrast. (Award of Merit.)

Pæony Langport Belle (Messrs. KELWAY).—A handsome full pink and white flower, very soft and delicate in tint. (Award of Merit.)

Pæony Fair Maid (Messrs. KELWAY).—A large, single flower, with incurving petals, bright rose, shading to the margins, and showing the dense cluster of yellow stamens. (First-Class Certificate.)

MARKETS.

COVENT GARDEN, June 24.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—ED.]

REMARKS.—English Cherries are now in the market; the fruits are of good quality but small. Southampton Strawberries have been a glut all the week up till to-day (Wednesday); consignments this morning were not large enough to meet the demands. English Peaches and Nectarines are a good trade, but supplies of best fruits are short. Trade both in the Vegetable and the Fruit departments is good. *E.H.R., Covent Garden, Wednesday, June 24, 1908.*

Potatos.

Up-to Date (grey soil)	80-	90
Maincrop (grey soil)	80-	90

REMARKS.—The demand for Jersey, St. Malo and Cherbourg Potatos continues fair; there are a few good samples from Kent, and these are selling slowly at the above prices. Lincoln and Blackland Potatos promise well and will probably be ready for digging in about a fortnight. *E. J. Newborn, June 24, 1908.*

COVENT GARDEN FLOWER MARKET.

POT PLANTS.

Ordinary flowering plants are plentiful, including good yellow Marguerites, but they do not sell so readily since the yellow summer flowering Chrysanthemums have been so extensively grown. The market nurserymen have an improved strain of this Chrysanthemum in plants of dwarfer and better habit generally. There are also improved varities of the ordinary white Marguerites. Fuchsias are plentiful, but during the whole season I have been unable to note any new or improved varieties. Verbenas have not sold well this season, except in the case of those required for special orders; they are plentiful in pink, white, purple and scarlet colours. Pelargoniums are good: Ivy-leaved varieties are not selling well, Zonals are offered at low prices, and the show or decorative varieties are not much in demand. The hybrid Crassulas are good, but the old *C. coccinea* seems to be the one most appreciated.

Mignonette is good from some growers, but from others it has rather a starved appearance. Great care needs to be exercised in purchasing flowering plants at this season as many are far advanced.

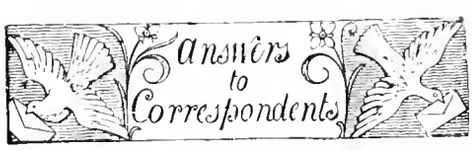
In bedding plants there are still some good samples, but the majority are either drawn or starved and stunted.

CUT FLOWERS.

Supplies of most things are abundant, but any special subject required needs to be ordered beforehand. Hardy flowers are the chief feature. The herbaceous Pæonies are of the very best varieties, but to obtain the names from the salesmen is an impossibility. It is the same with Pyrethrums. I learned from one special grower of new plants that a market grower bought the whole stock of one of the best varieties. The Cornflower (Centaurea cyanus) is seen in three distinct colours: white, pink, and a beautiful shade of blue. Iceland Poppies are also seen in improved varieties. Campanula isophylla alba is well grown, but it will not sell readily while Lilums are so plentiful. The best Lilium longiflorums have been down to the lowest price I have ever known. Lily of the Valley has been cheaper, yet in one trade paper the prices for this flower are quoted above the average. It is very difficult to furnish a correct price list. In the first place quality varies greatly, and some growers who send second quality produce to be sold on commission are under the impression that what they are sending is equal to the very best. All growers should visit the market. I have again had my attention called to the bad bunching and bad packing of some samples, and not only is this the case with Sweet Peas, but also with Roses, which are sometimes quite spoiled in transit. *A. H., Covent Garden, Wednesday, June 24, 1908.*

Obituary.

WILLIAM NEILD.—We regret to record the death of this gentleman, at the age of 57 years, on June 15. Deceased was connected with the Holmes Chapel Agricultural and Horticultural College, Cheshire. His remains were interred at St. Wilfrid's, Northenden, on the 17th inst.



ADDRESSES: *Bees, Limited.* These things are very annoying, but if owners choose to sell letters to such advertisers as those to which you refer, there can certainly be no illegality in the transaction.

APPLE SHOOTS: *G. W. S.* The fungus causing brown rot has attacked the branches. Clear away all diseased shoots and spray the bushes next spring with the Bordeaux mixture at half strength soon after the leaf-buds have expanded.

BEGONIA: *G. A. B.* There is no fungus disease present. The injury is in some way connected with culture, and strongly suggests too much moisture in the air and lack of ventilation.

BIRCH TREES: *D. B., Dumpies.* Probably there is some disease which is accountable for the failure. We think the best thing to be done will be to have the trees examined by an expert on the spot.

BOOKS: *D. J. B.* We do not know of a work dealing with fuhsia from the horticultural point of view you require.

BOUGAINVILLEA: *L. H. and Young Gardener.* This plant is most decorative when grown up a pillar in the conservatory or in a somewhat lofty greenhouse, so that the flowering sprays may depend from the roof and be seen from below, as they are more effective in this manner. They may also be trained up the rafters of any glasshouse provided with means of heating. Old plants should be cut back somewhat severely each winter, and in spring the growths should be thinned out so that each will have plenty of space and light to develop strongly. The plant may be propagated by cuttings taken from short young growths in spring, but care should be taken to detach them with a "heel," or it will be difficult to induce them to make roots.

BURMESE DENDROBIUMS: *McG., Putney.* We know of no book which deals exclusvely with Burmese Dendrobiums. Probably the most complete enumeration will be found in *The Orchids of Burma*, by B. Grant. The work is not illustrated, but good descriptions of the species, including those of the Andaman Isles, are given. The Dendrobiums, however, only form part of the work which enumerates also most of the Burmese Orchids.

CATERPILLARS ON APPLE TREES: *L. Fosbrooke.* The caterpillars are apparently those of the Winter Moth (Cheimatobia brumata). The larvæ of this species vary very much in colour, and the account you give of the habits of those you sent quite agree with those of the Winter Moth. The eggs are laid in the early winter. Grease-banding the stems to prevent the wingless females from ascending the trees is the best preventive. Spraying with arsenate of lead wash, or Paris green is very useful as soon as the fruit has set, or even now, as it poisons the leaves on which the caterpillars feed.

CORRECTION. In the note on Wynyard Park Gardens, p. 403, the number of bedding plants used there annually was, by a printer's error, made to read 7,000. The correct number is 75,000.

DIPTEROUS LARVA IN SEAKALE: *A. O. W.* Evidently a muscid of some kind, and apparently related to the genus Anthomyia. If we succeed in rearing the imago we will endeavour to identify it and communicate in a later issue. What was the extent of the injury?

FIGS: *C. B.* The spots are due to a fungus. Sponge the leaves at intervals of four days with a rose-coloured solution of Condy's fluid. Remove all diseased leaves and burn them.

INSECTS *F. R., Welbeck.* The small black chrysalis is that of a species of Tortrix; the "looper" caterpillars are possibly those of the "Mottled Umber" moth (Hybernia defoliaria), but as you have not supplied them with food they had shrivelled up so much as to render determination of the species well nigh impossible. The spider had disappeared. In future, pack your consignments of insects more carefully and place a little of the host plant with them.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. *Correspondents not answered in one issue are requested to be so good as to consult the following numbers.*

PLANTS: *L. G. M., Wilts.* 1, Neillia opulifolia lutea; 2, Pyrus Aucuparia; 3, Populus alba; 4, Laburnum alpinum; 5, Diervilla hybrida var. "Abel Carrière"; 6, Spiræa discolor; 7, Philadelphus grandiflorus; 8, Philadelphus coronarius; 9, Spiræa filipendula = *H. G. Luckhurst.* 1, Pseudotsuga Douglasii; 2, Abies Nordmanniana; 3, A. magnifica; 4, Thuya plicata; 5, Sequoia gigantea; 6, Cedrus atlantica glauca. *Caesar.* 1, Crataegus orientalis; 2, Spiræa prunifolia flore pleno.—*R. M. L.* Cytisus Scoparius sulphureus "Moonlight Broom." A well-known garden plant but rarely found growing wild. *H. W.* 1, Allium Moly; 2, Hemerocallis flava; 3, Olearia stellulata; 4, Clerodendron fœtidum; 5, Phlomis fruticosa; 6, Nepeta Mussini.—*J. H.* 1, Habenaria bifolia var. chlorantha; 2, Thalictrum aquilegifolium; 3, Campanula Portenschlagiana.—*Miss L. E.* 1, Rubus ulmifolius var. foliis variegatus; 2, Iris pallida var.; 3, Geranium Endressii.—*R. T.* 1, Miltonia Clowesii; 2, Oncidium crispum; 3, Odontoglossum Lindleyanum; 4, Brassia verrucosa; 5, Cœlia Baueriana.—*Hulfield.* Burlingtonia (Rodriguezia) fragrans.—*H. W.* Crinum Moorei, quite hardy if planted deeply, under a wall, in a sheltered situation.—*Rochuck.* Probably Dendrobium moschatum, but the flower is decayed and labellum wanting. It may be Dendrobium Dalhousieanum.—*A. K.* Buddleia globosa.—*J. H. B.*—Brassia verrucosa, a rather small form of it.—*F. H.* 1, Pteris longifolia; 2, Pteris tremula; 3, Polypodium aureum.—*Cymru.* 1, Dactylis glomerata variegata; 2, next week; 3, Eriophorum angustifolium (Cotton Grass); 4, Dictamnus Fraxinella.

ODONTOGLOSSUM CRISPUM: *J. W.* There is no fungus disease present. The leaves appear to be killed by some deleterious substance, probably the smoke complained of.

ONIONS: *F. E. A.* The Onions are attacked by eelworms—Heterodera devastatrix. The land will be infected, and should be treated with gas-lime or sulphate of potash before fresh crops are planted.

PEACH: *J. N. L. Q.* The injury cannot be attributed to insect or fungus, but is due to imperfect fertilisation, or some deficiency in nutriment.—*H. H.* The leaves are badly affected with fungus disease, and many of the shoots are quite dead. As you are situated in such a favourable locality for the cultivation of this and other choice fruits, and seeing also that the trees are trained to a wall facing to the south, we think that there must be something wrong with the constitution of the borders. The trees are so unsatisfactory that the best plan would be to clear them out, and after making suitable borders, start with a fresh stock.—*Royal George.* The stones have not formed perfectly. We should be inclined to water the border with lime water, and in the winter season it will be well to fork in a little lime into the surface soil.

PEAR LEAVES: *Islander.* The little cigar-shaped objects on the Pear leaves are the larval cases of two species of small moths belonging to the Coleophora. The young larvæ usually mine the leaves at first, and when partly developed protect their bodies with portions of the leaves of the food plant in which they pass the rest of their lives. Spray with Paris green (poison) at the rate of 2 ozs. to a gallon of water. Two applications may be necessary. Your record is of much interest, as these insects rarely attack fruit trees.

ROSE: *S. J. R.* The disease is black spot, caused by a fungus named Actinonema rosæ. Spray the plants at intervals of four days with a solution of liver of sulphur—one ounce in three gallons of water. Pick off and burn any badly diseased leaves.

ROSE BUSHES: *H. N. L.* The mixture has evidently scorched the foliage. The proportions used were correct, but probably the lime was more or less air slacked, for when this is the case it always produces scorch.

SOUVENIR DE LA MALMAISON CARNATION: *G. W. I.* The injury is caused by the punctures of aphides. Fumigate the house with tobacco or the XL-All vaporising compound.

SULPHATE OF POTASSIUM: *A. H.* The term used in a contemporary was doubtless intended for sulphate of potassium, a manurial element. The other substance is an insecticide.

WISTARIA: *Col. H. C.* All you can do with the Wistaria is to thin out the growths each season and expose them to all the sunlight possible. This plant flowers much more freely when it has attained to some considerable age, and it may be that your specimen will eventually flower satisfactorily. The piece you have enclosed is quite dead, but this may be from some local cause, and there is nothing in the specimen itself to lead us to suppose that the plant is affected with disease.
